SAPUI5: UI Development Toolkit for HTML5

THE BEST RUN SAP

Content

SAPUI5: UI Development Toolkit for HTML5

Create apps with rich user interfaces for modern web business applications, responsive across browsers and devices, based on HTML5. (Documentation patch 1.75.0)

SAPUI5 offers powerful development concepts:

- One consistent user experience for your apps
- Responsive across browsers and devices - smartphones, tablets, desktops
- Built-in extensibility concepts at code and application level
- Data binding types and Model-View-Controller (MVC)
- Feature-rich UI controls for handling complex UI patterns and predefined layouts for typical use cases. UI controls automatically adapt themselves to the capabilities of each device.
- Full translation support
- Keyboard interaction support and accessibility features

And many more....

Check the SAPUI5 playlist in the SAP Technology YouTube channel for the latest highlights videos!

SAP Fiori apps are built with SAPUI5 and follow the SAP Fiori design guidelines to ensure consistent design and a high level of design quality. See SAP Fiori Design Guidelines.

For more information about SAP Fiori, see http://www.sap.com/fiori

> → Tip
>
> Looking for the Demo Kit for a specific SAPUI5 version?
>
> Check at https://ui5.sap.com/versionoverview.html which versions are available. You can view the version-specific Demo Kit by adding the version number to the URL, e.g. `https://ui5.sap.com/1.38.8/`
>
> For more information, see Versioning of SAPUI5 [page 29].
>
> Need a PDF version of the SAPUI5 documentation? Go to https://help.sap.com/viewer/p/SAPUI5.

What's New in SAPUI5

Find out what's new in the latest versions of SAPUI5.

Check the latest videos in the SAPUI5 playlist in the SAP Technology YouTube channel and the OpenUI5 YouTube channel.

What's New in SAPUI5 1.75

With this release SAPUI5 is upgraded from version 1.74 to 1.75.

New Features

UI Adaptation: Embedding External Content

If you have enabled an app for UI adaptation (see SAPUI5 Flexibility: Enable Your App for UI Adaptation [page 1450]), users of this app can now embed external content, such as maps or videos, as iFrames. This feature is available for key users at runtime in UI adaptation mode as well as for developers within the SAPUI5 Visual Editor in SAP Web IDE.

Improved Features

Card Explorer

We have introduced a schema validation feature in our samples in the Card Explorer. With this option, developers can see a more detailed report for mistakes inside the card manifest. Things like wrong names of properties, bad property types or bad structures are easily spotted. For more information, explore the samples in Card Explorer.

Currency Codes

When displaying ISO currency codes using `sap.ui.core.format.NumberFormat`, `sap.ui.model.type.Currency` or `sap.ui.model.odata.type.Currency`, the currency code is now displayed by default after the amount, ignoring locale, in order to be consistent with SAP design guidelines. The core configuration parameter `trailingCurrencyCode` can be used to switch the behavior globally.

If currency symbols are enabled (formatting option `currencyCode: false`), they continue to follow locale-specific placement.

SAPUI5 OData V2 Messages

With the new version of the SAPUI5 OData V2 model, the target of server messages is shortened by removing associated pairs of navigation properties. For example, a `/SalesOrderSet('1')/ToLineItems(SalesOrderID='1',ItemPosition='10')/ToHeader/GrossAmount` message target gets reduced to `/SalesOrderSet('1')/GrossAmount` if the `ToLineItems` and `ToHeader` navigation properties have the same relationship in the service metadata. If the second navigation property references a collection, the message target path is reduced only if the referenced entity is the same as without the navigation.

SAPUI5 OData V4 Model

The new version of the SAPUI5 OData V4 model introduces the following features:

- When displaying aggregated data with a list binding using either the `$$aggregation` binding parameter or `sap.ui.model.odata.v4.ODataListBinding#setAggregation`, you can filter by properties that are part of the original entity set but not of the result set. Note that these filters need to be provided as `sap.ui.model.Filter` objects.
- `sap.ui.model.odata.v4.Context#requestSideEffects` now supports updating in parent bindings by specifying navigation properties to the parent entities in the path expressions. The respective navigation properties from the parent binding to the binding of the context and back to the parent need to be marked as partners in the metadata.
- When using `autoExpandSelect`, paths with navigation properties can now be added to `$select`. The binding will evaluate this and automatically derive `$select` and `$expand`.
- For `sap.ui.model.odata.v4.ODataPropertyBinding`, a `$$noPatch` binding parameter is provided, so that values can be changed in the model without updating them in the back end.
- The `resume` method of the `v4.ODataContextBinding` and `v4.ODataListBinding` classes now works synchronously.

> ! Restriction
>
> Due to the limited feature scope of this version of the SAPUI5 OData V4 model, check that all required features are in place before developing applications. Double-check the detailed documentation of the features, as certain parts of a feature may be missing. While we aim to be compatible with existing controls, some controls might not work due to small incompatibilities compared to `sap.ui.model.odata.(v2.)ODataModel`, or due to missing features in the model (such as tree binding). This also applies to smart controls (`sap.ui.comp` library) that do not support the SAPUI5 OData V4 model, as well as controls such as `TreeTable` and `AnalyticalTable`, which are not supported in combination with the SAPUI5 OData V4 model. The interface for applications has been changed for easier and more efficient use of the model. For a summary of these changes, see Changes Compared to OData V2 Model [page 971].

For more information, see OData V4 Model [page 918], the API Reference, and the Samples in the Demo Kit.

Title Support in Nested Components

The `title` property can now also be defined on routing targets of type `Component`. When set with a binding syntax, it is resolved in the context of the root view of the component loaded by this target.

The router of a nested component may also have a `title` property defined on its own target(s) and eventually fire its own `titleChanged` event once such a target is displayed. A new configuration `propagateTitle` allows the `titleChanged` event to propagate from an individual `Component` target to the router of its parent component. In the routing configuration, this can also be enabled for all `Component` targets, so that it is not necessary to define the `propagateTitle` property on each `Component` target.

For more information, see Using the title Property in Targets [page 1083] and Enabling Routing in Nested Components [page 1086]. In addition, the Sample application introduced in the previous release to feature routing of nested components has been enhanced. It now shows how the new title definition and title propagation could be used in an application built with nested (or reuse) components.

Improved Controls

`sap.m.InitialPagePattern`

We have introduced the initial page floorplan as a Demo Kit sample. The floorplan allows users to navigate to a single object to view or edit it. The interaction point on the screen is a single input field and it relies on assisted input to direct the user to the object in as few steps as possible (using features such as value help and live search). For more information, see the SAP Fiori Design Guidelines and the Sample.

`sap.m.Link`

The `text` property can now be changed using UI adaptation at runtime. This enables key users to provide meaningful link text according to the application context.

For more information, see the Samples.

`sap.m.MessageBox`

We have introduced a new `emphasizedAction` property. This allows developers to specify which button in the dialog will receive the type `Emphasized`. If `emphasizedAction` is empty with no actions provided, the default value applies. For more information, see the API Reference and the Samples.

`sap.m.ObjectStatus`

We have enhanced the `sap.ui.core.IndicationColor` palette. Three new colors were added to the palette as numbers 6, 7, and 8. These colors enable developers to represent statuses that don't require a meaning in the sense of good-bad, but should be visually distinguishable. For example, statuses such as Updated, New, or Active. For more information, see the API Reference and the Sample.

`sap.ui.comp.smartfilterbar.SmartFilterBar`

- The export and import functionality of the `SelectionVariant` is now enhanced and includes the related texts that are used in the filters when fields are set. The feature is available without further configuration. For more information, see the Sample.
- We have introduced the option to define different columns in the table of the `ValueHelpDialog` and the suggestion list of the `SmartFilterBar`. In the `ValueList` annotation, each parameter can be statically annotated as important using the `Importance` annotation with `EnumMember` set to `High`. For more information, see the API Reference.
- We have enabled the `useDateRangeType` property so that it can be modified from the UI adaptation at runtime.

`sap.ui.integration.widgets.Card`

We have enhanced the capabilities of the Adaptive Card (Experimental).

- You can now load the Adaptive Card manifest/descriptor from a URL.
- The Adaptive Card supports templating, which enables the separation of data from the layout.

For more information, see the Adaptive Card in the Card Explorer.

`sap.ui.table.AnalyticalTable, sap.ui.table.Table, sap.ui.table.TreeTable`

A more comprehensive message text is now shown if no data is available because all table columns are hidden. For more information, see the Sample.

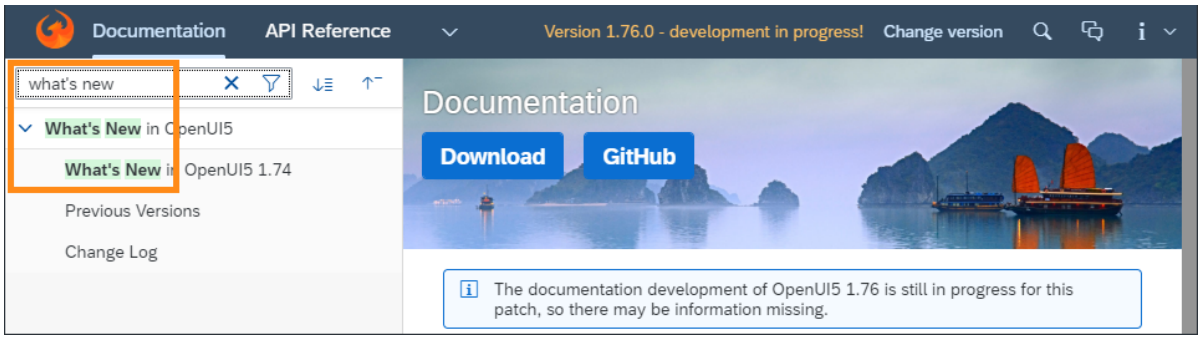
SAP Fiori Elements

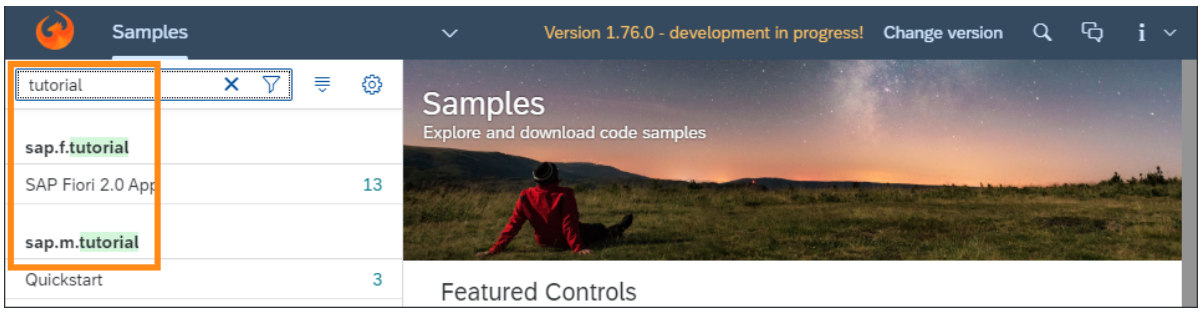
- **Option to Show an Error Message on an Empty Table in the Object Page**
  You can now show an error message strip if a table is empty or if any of the table rows contain an error in a section or subsection of an Object Page.
- **List Report Page Loaded with Data on Launch**
  By default, the list report page is loaded with data when an application is launched. For more information, see List Report Elements [page 1623].
- **Option to Set Vertical Alignment for Responsive Tables in List Report and Object Pages**
  You can now set the vertical alignment property for the whole responsive table via a manifest property `tableColumnVerticalAlignment` under the settings of `sap.ui.generic.app`. You can set the value of this string to `Top`, `Middle`, and `Bottom`.
- **Option to Define the Table Type for Each Tab of a List Report**
  You can now define the table type for tabs with different entity sets in a List Report page. For more information, see Multiple Views on List Report Tables [page 1645] and Defining Multiple Views on a List Report with Different Entity Sets and Table Settings [page 1656].

Demo Kit Improvements

Search Highlighting in the *Documentation* and *Samples* sections

The search highlighting functionality is now also available in the *Documentation* tree filter and the *Samples* list.





What's New in SAPUI5 1.74

With this release SAPUI5 is upgraded from version 1.73 to 1.74.

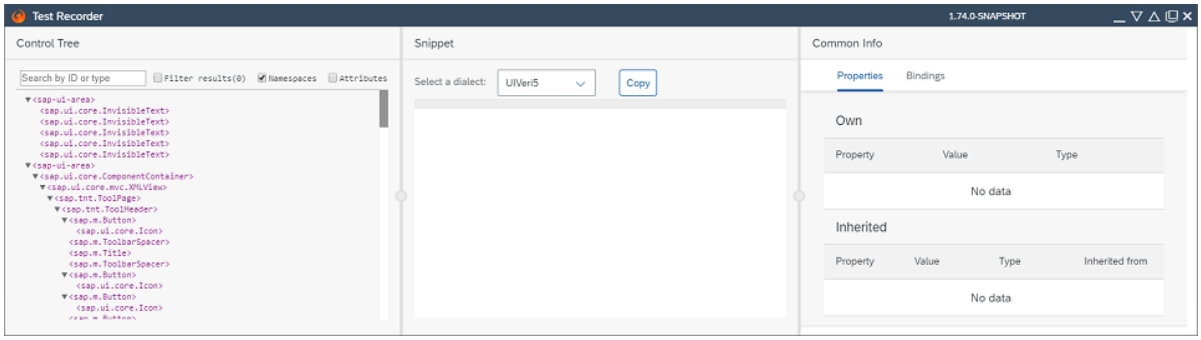
New Features

Rule Builder Control

You can model a text rule to perform an append operation on data objects or attributes in expression language 2.0. For more information, see **Operations** in Features [page 548].

Test Recorder

The Test Recorder tool is now part of the SAPUI5 framework and is available in all browsers. Use it in any SAPUI5 app to inspect the rendered user interface, view the control properties, and get hints about writing tests. The tool is aligned with the two official SAPUI5 testing tools – OPA5 and UIVeri5.



For more information, see Test Recorder [page 1251].

Improved Features

`Card Explorer`

We have enhanced the functionality to download samples from the Card Explorer, and now there are 3 optional file formats available: JSON, ZIP, and CARD. For more information, see Card Explorer.

Navigation in Nested Components

In recent releases, the capabilities to Navigate with Nested Components [page 1090] were enhanced significantly. In addition to the available documentation, a Sample has been added to showcase some fundamental possibilities of using components to structure applications and how to interconnect them via routing.

Negative Predefined CSS Margin Classes

We've introduced the following negative CSS margin classes to help you align controls that have their own default margins:

- `sapUiTinyNegativeMarginBeginEnd`
- `sapUiSmallNegativeMarginBeginEnd`
- `sapUiMediumNegativeMarginBeginEnd`
- `sapUiLargeNegativeMarginBeginEnd`

For more information, see Using Predefined CSS Margin Classes [page 1046] and the Sample.

Responsive Padding Enablement

We've introduced responsive paddings to the `sap.m.IconTabBar`, `sap.m.ObjectHeader`, and `sap.m.TabContainer` controls. For more information, see Enabling Responsive Paddings [page 1052].

SAPUI5 OData V4 Model

The new version of the SAPUI5 OData V4 model introduces the following features:

- The `autoExpandSelect:true` model setting has been enhanced for property bindings that are added later.
- We have added the `sap.ui.model.v4.ODataListBinding.getDownloadUrl` method.
- `sap.ui.model.v4.AnnotationHelper.format` can now be used for operation parameters.
- For messages returned in error responses of operation calls, targets pointing to operation parameters are now parsed correctly.
- The `sap.ui.model.v4.Context.setProperty` method can be used to set properties locally on the client by specifying `null` as the `groupId`. The set value is then not included in PATCH and POST requests to create the new entity.
- Annotation targets for (overloaded) bound operations in 4.01 Format are also supported in value list metadata.

> ! Restriction
>
> Due to the limited feature scope of this version of the SAPUI5 OData V4 model, check that all required features are in place before developing applications. Double-check the detailed documentation of the features, as certain parts of a feature may be missing. While we aim to be compatible with existing controls, some controls might not work due to small incompatibilities compared to `sap.ui.model.odata.(v2.)ODataModel`, or due to missing features in the model (such as tree binding). This also applies to smart controls (`sap.ui.comp` library) that do not support the SAPUI5 OData V4 model, as well as controls such as `TreeTable` and `AnalyticalTable`, which are not supported in combination with the SAPUI5 OData V4 model. The interface for applications has been changed for easier and more efficient use of the model. For a summary of these changes, see Changes Compared to OData V2 Model [page 971].

For more information, see OData V4 Model [page 918], the API Reference, and the Samples in the Demo Kit.

Improved Controls

`sap.m.Avatar`

We've added *remove* and *reveal* actions in the `Avatar` design-time metadata. Now, the control can be removed and revealed when using UI adaptation at runtime. For more information, see the Samples.

`sap.m.ColorPalette`

We have introducted a *Recent Colors* section, showing the last 5 recently used colors. This feature is enabled by default, making it is easier to find and select the exact colors. For more information, see the API Reference and the Sample.

`sap.m.DateRangeSelection`

We have introduced the ability to select month and year ranges. This improves the user experience when only a month or a year range has to be selected, and is defined by the `displayFormat` property. For more information, see the API Reference and the Sample.

`sap.m.List, sap.m.Table, sap.m.Tree`

The busy indicator is now displayed in the center of the visible area of the UIs of these controls and is no longer vertically centered and therefore not always visible. For more information, see the Sample.

`sap.m.NavContainer`

In version 1.69, the default value for the `defaultTransitionName` property was visually updated to behave as a slide & fade animation and the classic slide animation was no longer an option. Now, we've added the previous slide behavior as a new type of transition. To use it, set the `defaultTransitionName` property to `baseSlide`. For more information, see the API Reference and the Sample.

`sap.m.NotificationListItem`

The avatar background color can now be managed by the application developer using the new `authorAvatarColor` property. Now, if any of the `authorPicture` or `authorInitials` properties are not set, the default icon will not be displayed. For more information, see the API Reference and the Sample.

`sap.m.plugins.DataStateIndicator`

This plugin for the table controls (`sap.m.List, sap.m.Table, sap.ui.table.Table`) allows you to implement binding-related messages and show them on the UI using a message strip. For more information, see the API Reference and the Sample.

`sap.m.Select`

With the new `required` property, you can now indicate whether user input is required. This property is helpful for accessibility purposes when a single relationship between the field and a label can't be established, for example, when one label exists for multiple fields. For more information, see the API Reference.

`sap.m.StandardListItem`

The new `infoStateInverted` property changes the rendering behavior of the information state and information text. If it is set to `true`, the color defined by the `infoState` property is then shown as the background color of the information text. For more information, see the API Reference and the Sample.

`sap.m.Table`

A more comprehensive message text is now shown if no data is available because all table columns are hidden. For more information, see the Sample.

`sap.m.ViewSettingsDialog`

We have introduced a new button to display only the selected items in the filter tab, and to hide items that are not selected. This button works in combination with the Search field, so the displayed items are both filtered by title and selection. For more information, see the API Reference and the Sample.

`sap.m.Wizard`

We have enhanced the `sap.m.Wizard` control for better integration in the `sap.f.DynamicPage`. In order to make use of it, you need to make certain configurations. For more information, see the API Reference.

`sap.tnt.InfoLabel`

We have introduced the option to add an icon to the `sap.tnt.InfoLabel` content. It is defined by the new `icon` property. For more information, see the API Reference and the Sample.

`sap.ui.comp.smartfield.SmartField, sap.ui.comp.smartfilterbar.SmartFilterBar`

We've introduced support for fiscal dates. The service metadata property must be of type `Edm.String` annotated with one of the fiscal annotations (`IsFiscalYear`, `IsFiscalPeriod`, `IsFiscalYearPeriod`, `IsFiscalQuarter`, `IsFiscalYearQuarter`, `IsFiscalWeek`, `IsFiscalYearWeek`, `IsDayOfFiscalYear`). For more information, see the API Reference for `SmartField`, the API Reference for `SmartFilterBar` and the Sample for `SmartFilterBar`.

`sap.ui.comp.smartfilterbar.SmartFilterBar, sap.ui.comp.smarttable.SmartTable`

We've updated the available exclude operators to match the include operators for each field type. The change affects the *Define Conditions* tab of the `ValueHelpDialog` in `SmartFilterBar` and the *Filter* tab of `TablePersoDialog` in `SmartTable`. For more information, see the Sample for `SmartFilterBar` and the Sample for `SmartTable`.

`sap.ui.comp.valuehelpdialog.ValueHelpDialog`

We've improved the behavior of the `ValueHelpDialog` basic search for `SmartFilterBar` and `SmartField`. Now, only the entered (or modified) value is taken over into the basic search. The search is triggered automatically when the dialog opens and takes over the value into the basic search (if it's not empty). Only the entered characters are taken, regardless if the suggestion list is displaying a typeahead. For more information, see the Sample for `SmartField` and the Sample for `SmartFilterBar`.

`sap.ui.export.Spreadsheet`

This class has been further improved to facilitate the export functions. The class now supports `sap.ui.model.Binding` as a `dataSource` parameter. For more information, see the API Reference.

`sap.ui.integration.widgets.Card`

- A new experimental Calendar Card type is now available . Its purpose is to give an overview of a single entity (a person, for example). It consists of an interactive calendar, legend, and a schedule. For more information, see Calendar Card in the Card Explorer.
- We have enabled Data Sources to be used in the descriptor for `sap.ui.integration.widgets.Card`. Data Sources are named and reusable manifest entities that hold configuration settings for services. Referenced using special double-bracketed syntax, they are used to construct data request URLs. Data Sources are defined in the `sap.app` part of the manifest. For more information, see Data Sources in the Card Explorer.
- We have introduced new number formatters to represent the data on the UI in human-readable format. Now we have predefined number formatters for:
  - Currency
  - Date and Time
  - Floating-point numbers
  - Integers
  - Percent
  - Units of measurement

  For more information, see Card Formatters in the Card Explorer.
- We now also support objects as values for manifest parameters. Until now only string values were supported. For more information, see Manifest Parameters section in the Card Explorer.
- We have introduced a new experimental type of card - Adaptive Card. With this type of card, you can visualize and reuse cards created using the Microsoft Adaptive Cards specification and manifest, while achieving fully adapted SAP Fiori 3 user experience, out of the box. For more information, see Adaptive Card in the Card Explorer.

`sap.uxap.ObjectPageLayout`

You can now move the corresponding section numbers that are displayed in the `AnchorBar` when using UI adaptation at runtime. For more information, see the Samples.

SAP Fiori Elements

- **Smart Multi-Input Control in Smart Tables**
  It is now possible to include a smart multi-input field in a smart table on an object page. For more information, see Using the Smart MultiInput Control on the Object Page [page 1720].
- **Flexible Column Layout: Displayed Item on Object Page Highlighted in Master List**
  The navigation row in the table is highlighted in blue to correlate with the object being displayed in applications with flexible column layout.
- **Object Page Saves and Restores State of Control Variants**
  This means that the selected table variants are stored in the same way as the control variants for the list report page.
- **Configuration of Relevant Links**
  SAP Fiori Elements now gives you the option of configuring relevant links in Related Apps. For more information, see Enabling the Related Apps Button [page 1697].
- **Option to Set Initial Expansion Level in List Report and Analytical List Page Tables**
  You can now set `initialExpansionLevel` using the `PresentationVariant` annotation to set the number of expanded levels for tables and trees. For more information, see Initial Expansion Level for Tables in List Reports & Analytical List Pages [page 1620].
- **Themes**
  SAP Quartz Light is now available by default for applications that are generated by the SAP Web IDE wizard and plugin.

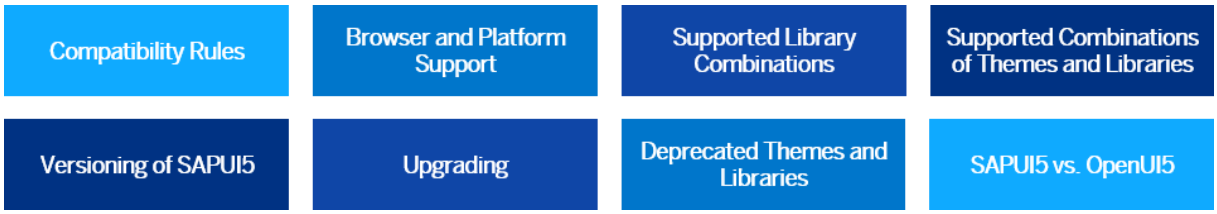
Documentation

Performance Checklist

Ensuring that your SAPUI5 apps run fast is an important topic in application development. To support you in this task, we have improved the existing performance-related documentation as well as added some new information. Please use the comprehensive Performance Checklist [page 690] as a starting point for best practices to help you to review and speed up your SAPUI5 apps.

Read Me First

Before you start using SAPUI5 productively, please read the **important information** in the section. Here you read everything you need to know about supported library combinations, the supported browsers and platforms, and so on.



- Compatibility Rules [page 17]
- Browser and Platform Support [page 20]
- Supported Library Combinations [page 26]
- Supported Combinations of Themes and Libraries [page 27]
- SAPUI5 vs. OpenUI5 [page 37]
- Deprecated Themes and Libraries [page 34]
- Upgrading [page 31]
- Versioning of SAPUI5 [page 29]

Compatibility Rules

The following sections describe what SAP can change in major, minor, and patch releases. Always consider these rules when developing apps, features, or controls with or for SAPUI5.

> ⚠ Caution
>
> As an app developer, **never** do the following:
>
> - Never manipulate HTML/CSS via JavaScript (`domRef.className = "someCSSClass";`) or directly via CSS, for example. Always follow our recommendations under CSS Styling Issues [page 1464].
> - Never use or override "private" functions that are not part of the API Reference. Private functions are typically (but not always) prefixed with a preceding "_". Always double-check the API Reference, private functions are not listed there.

API Evolution

Unless otherwise mentioned, the word "API" in this section refers to "public API", meaning functions, classes, namespaces, controls along with their declared properties, aggregations, and so on. The sole definition of the

public API is the API Reference, which is included in the SAPUI5 Demo Kit. Features that are **not** mentioned there are **not** part of the API.

The following rules apply for introducing new APIs or making incompatible changes to existing APIs:

Major release (**x**.yy.zz): A new major version can introduce new APIs or make incompatible changes to existing APIs.

Minor release (x.**yy**.zz): A new minor version can introduce new APIs but must not contain incompatible changes to **any** APIs.

Patch release (x.yy.**zz**): A new patch version only contains fixes to the existing implementation, but does not usually contain new features or incompatible API changes.

> **i** Note
>
> Exceptions to these rules are possible, but only in very urgent cases such as security issues. Such exceptions are documented in the Change Log.

Compatible Changes

The following changes to existing APIs are compatible and can be done anytime:

- Adding new libraries, controls, classes, properties, functions, or namespaces
- Generalizing properties, that is moving properties up in the inheritance hierarchy
- Adding new values to enumeration types; this means that when dealing with `enum` properties, always be prepared to accept new values, for example, by implementing a `"default"` or `"otherwise"` path when reacting on `enum` values.

Incompatible Changes

The following is not part of the public API and may **change in patch and minor releases**:

- Open source libraries (see Third-Party Open Source Libraries [page 20])
- Log messages

The following changes to existing APIs are incompatible, but **can be done in a new major release**:

- Renaming an API (library, namespace, function, property, control, events, and so on)
- Removing support for parameters
- Removing support for configuration entries
- Reducing the visibility of an API; this does not break JavaScript applications, but changes the contract
- Removing or reordering parameters in an API signature
- Reducing the accepted value range, for example, parameter of a function
- Broadening the value range of a return value (or property). Exception: enumerations
- Moving JavaScript artifacts (namespaces, functions, classes) between modules
- Replacing asserts with precondition checks
- Moving properties (and so on) down in the inheritance hierarchy

- Changing the name of `enum` values
- Changing defaults (properties, function parameters)
- Renaming or removing files

Inheritance

Inheriting from SAPUI5 objects (e.g. by calling `sap.ui.extend` on an existing control to add custom functionality) may endanger the updatability of your code.

When overriding an SAPUI5 lifecycle method (such as `init`, `exit`, `onBeforeRendering`, and `onAfterRendering`), you must make sure that the super class implementation is called, for example like this:

```
MyClass.prototype.onAfterRendering = function() {
  SuperClass.prototype.onAfterRendering.apply(this);
  // do your additional stuff AFTER calling super class
}
```

SAP might add, remove, or change the internal implementation of the parent class at any time. Especially, you should not rely on the following functionality:

- Internal structures and methods that are not part of the public API
- Any internal logic and behavior of the object that is not reflected in the public API
- The parent hierarchy of objects especially for composites where the API parent differs from the real parent (e.g. parent object > internal object > child object). For more information, see API Reference: `sap.ui.base.ManagedObject`.
- All rendering functionality of a control, including the HTML structure and CSS classes
- Naming collisions with SAPUI5 structures and methods. SAPUI5 might introduce new API or internal structures at a later point in time that collide with your implementation. To avoid collisions, a custom prefix may be applied. Don't use namespaces starting with `sap.m.*` or `sap.ui.*` in your app.

We recommend that you test inherited classes very carefully after updating SAPUI5 to make sure that the extended functionality is still working as expected.

Deprecation

If possible and appropriate, we mark old artifacts as deprecated and create new artifacts, instead of making incompatible changes. A deprecation comment in the corresponding API documentation, and perhaps also a log entry in the implementation, explain why and when an artifact has been deprecated and include tips on how to achieve the same results without using deprecated functionality.

Experimental API

Some features or controls delivered with the current SAPUI5 version are flagged as "experimental". These experimental features and controls are not part of the released scope of the delivered SAPUI5 version. Do not

use experimental features or controls in a productive environment, or with data that has not been sufficiently backed up.

Experimental features and controls can be changed or deleted at any time without notice, and without a formal deprecation process. They may also be incompatible to changes provided in an upgrade.

Third-Party Open Source Libraries

SAPUI5 contains and uses several third-party open source libraries, such as `jQuery`. These libraries can also be used by applications and/or custom control libraries, but the SAPUI5 compatibility rules described in this document do not apply to these third-party libraries.

If you want to use the third-party open source libraries included in SAPUI5, note the following restrictions:

- SAP decides which versions and modules of the used libraries are provided.
- SAP can upgrade to a higher version of the used libraries even within a patch release.
  If we change to a new default version of a library, we document our findings that might have an effect on SAPUI5 apps (see Upgrading [page 31]). Make sure that you adapt your code if necessary!
- For important reasons such as security, SAPUI5 can stop providing a library at any time.
- The third-party libraries are provided "as is". Extensions, adaptations, and support are not performed or provided by SAP.

> **i Note**
>
> Do not use different versions of these libraries as this might lead to unforeseen side effects..

For a list of the third-party open source software used in SAPUI5, see the *Included Third-Party Software* link in the *About* dialog in the Demo Kit.

API Reference

Browser and Platform Support

Browser and platform support for the SAPUI5 libraries on iOS, Android, macOS, and Windows platforms.

> **i Note**
>
> The single source of truth about supported browsers and platforms is the Product Availability Matrix (PAM) that you can find at https://support.sap.com/pam. SAPUI5 is not a product of its own, so please check the PAM for the product you're using SAPUI5 with. For more information, see SAP Note 1716423.
>
> The following sections only contain additional information on restrictions and platform support information for specific SAPUI5 libraries in a summarized form.

As SAPUI5 is based on CSS3, HTML5, and the ECMAScript 5 (ES5) JavaScript API, only browsers with HTML5 capabilities are supported. In general, only major versions that are also supported by the respective platform can be supported by the SAPUI5 framework.

> **! Restriction**
>
> We currently do not guarantee that newer ECMAScript standards, such as ES6/ES2015, work with SAPUI5.

Depending on the platform your SAPUI5 apps run on, different browsers in different versions are supported. If you know which platform and which browsers are used by your users, you can decide on which libraries to use for your app.

Overview of Supported Browsers, Platforms, and Reference Devices

The following tables give a general overview of the browsers, platforms, and reference devices supported by the main SAPUI5 libraries.

Browser and Platform Support Matrix

> **i Note**
>
> SAPUI5 plans to end the support for Microsoft Internet Explorer 11 as future direction (end of 2021 or later). Legacy web applications, which use active browser plugins that require Microsoft Internet Explorer 11, cannot run embedded inside an SAP Fiori launchpad that depends on a SAPUI5 version released after support ended.
>
> Integration of SAPUI5 applications in SAP GUI for Windows through the SAP HTML Control also use the Microsoft Internet Explorer Control. Alternatives for this Microsoft Internet Explorer Control are presently under investigation.

1) The next stable SAPUI5 release that comes after SAPUI5 1.71 will be the last SAPUI5 release to support Microsoft Edge (EdgeHTML).
2) In regards to handling touch events, there are some issues with Windows 8. For more information, see Windows 8 Support - Known Issues [page 2202].
3) Internet Explorer 11 requires add-ons *XML DOM Document* and *XML DOM Document 3.0* to be activated for XML parsing support.
4) Not supported for `sap.ui.commons` and `sap.ui.ux3`.
5) Not supported for `sap.gantt`. Note that gantt charts consuming `sap.gantt` can be displayed on tablet devices.
6) Not supported for `sap.ui.vbm`.
7) Not supported for `sap.ui.vk`.

Supported Reference Devices

For mobile operating systems, support is restricted to specific reference devices.

When creating support incidents, make sure that the device you refer to belongs to the listed ones:

> **i Note**
>
> Touch-enabled devices are not supported by the `sap.ui.commons`, `sap.ui.ux3` and `sap.gantt` libraries.

Platform	Device	End of Support Date
iOS SAP always supports the 2 latest releases of the iOS operating system, not exceeding 3 years from vendor release date. SAPUI5 supports Apple iPhone and iPad series until 3 years from the vendor device release date, except defined otherwise.	Apple iPhone 8	September 2020
	Apple iPhone X	November 2020
	Apple iPhone XS	September 2021
	Apple iPhone XR	October 2021
	Apple iPhone 11	September 2022
	Apple iPad (5th)	March 2020
	Apple iPad Pro (2nd)	June 2020
	Apple iPad (6th)	March 2021

Platform	Device	End of Support Date
	Apple iPad Pro (3rd)	October 2021
	Apple iPad Air (3rd)	March 2022
	Apple iPad Mini (5th)	March 2022
	Apple iPad (7th)	September 2022
Android Android OS based devices are very fragmented in matters of operating system variants and hardware diversity. SAPUI5 supports Samsung Galaxy S and Galaxy Tab S series until 3 years from vendor device release date, except defined otherwise.	Samsung Galaxy S8	April 2020
	Samsung Galaxy S9	March 2021
	Samsung Galaxy S10	March 2022
	Samsung Galaxy Tab S3	March 2020
	Samsung Galaxy Tab S4	August 2021
	Samsung Galaxy Tab S5e	April 2022
	Samsung Galaxy Tab S6	August 2022
Windows SAPUI5 supports Microsoft Surface Pro reference devices until 3 years from vendor device release date, except defined otherwise.	Microsoft Surface Pro (2017)	June 2020
	Microsoft Surface Pro 6	October 2021
	Microsoft Surface Pro 7	October 2022
	Microsoft Surface Pro X	November 2022

Additional Information

- **General**
  - Internet Explorer 11 (IE11) provides specific document and enterprise modes for compatibility reasons. SAPUI5 supports only the IE11 document mode. For backward compatibility, IE11 allows to enable a special enterprise mode that can simulate either an IE8 or IE7 within an IE11, which is NOT supported for SAPUI5 apps. This functionality should be used only for critical apps that require an older browser version to run. For more information, see "Fix web compatibility issues using document modes and the Enterprise Mode site list " in the Microsoft Windows IT Center.
  - The PhantomJS browser is not supported. If you are using it for testing purposes, make sure that you use version 2.x or higher. Otherwise you may get an error message, such as "`TypeError: 'undefined' is not a function (evaluating 'f.bind(null,undefined)')(line 146)`".
  - `sap.ui.core`, `sap.ui.layout`, `sap.ui.unified` are basic libraries, supporting all platforms or browsers that are supported by any of the other libraries.
- `sap.m`
  - For the `maxLines` property of the `sap.m.Text` control, multiline ellipsis handling is not supported for all browsers and devices and is not supported at all for right-to-left text direction. For more information, see Visual Degradations [page 24].
- `sap.ui.vk` - the supported browsers are all WebGL-compatible.

Visual Degradations

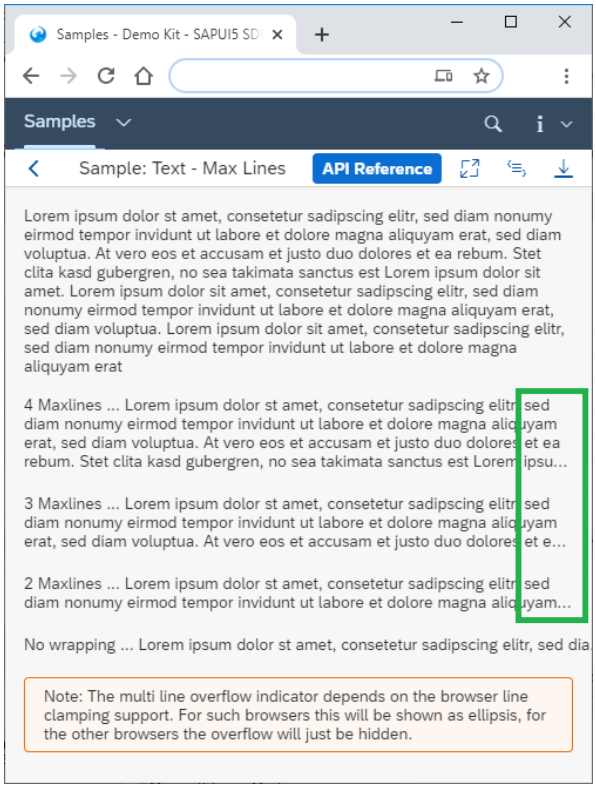
Depending on the combination of device and browser, visual degradations may occur in the `sap.m` library.

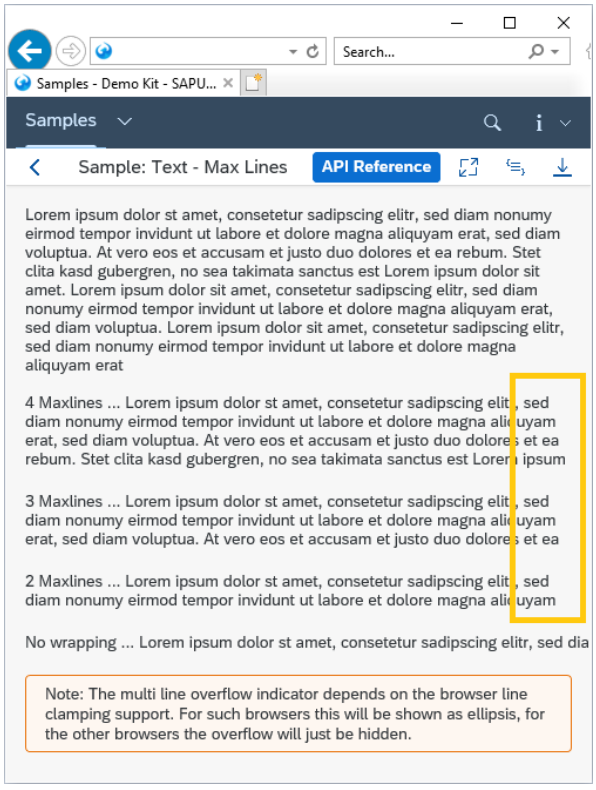
The following sections give an overview of the known degradations.

sap.m.Text - maxLines (property), sap.m.Text - text (property), sap.m.ObjectListItem - title (property), sap.m.ObjectHeader - title (property)

The visual aid for indicating multiline overflow is an ellipsis at the end of a line. This ellipsis is displayed if the text string exceeds the maximum number of lines displayed on screen. Depending on the line-clamping support offered by your browser, this visual aid may not be displayed at all, meaning the text is simply truncated without any visual indication that it is incomplete. The table below outlines which browsers fail to support the multiline ellipsis handling of the `maxLines` property, and also shows examples the visual degradation along with what the display should look like when it is supported:

Table 1: maxLines Visual Degradations

What it Should Look Like	Visual Degradation
Google Chrome	Internet Explorer 11
	




placeholder Property in sap.m.Input and sap.m.TextArea

As there is no W3C specification for how to use the placeholder property, browser handling for this property varies greatly. Some browsers use a native placeholder property, but for browsers that do not support this, SAP implements its own placeholder version.

The following overview outlines which browsers use which version, and which limitations or degradations apply in each case for the `sap.m.Input` control and `sap.m.TextArea` control.

Table 2: placeholder Property in sap.m.Input

Browser	Situation
Google Chrome	Google Chrome supports the native placeholder property and displays the ellipsis correctly, indicating that the placeholder text stretches beyond the field that is currently visible Internet Explorer Version 11	This version supports the native placeholder property but does not display the ellipsis, instead it simply truncates the placeholder text string  **i Note** If you focus in the field, the placeholder disappears from view. If you leave the focus without typing anything, the placeholder is then displayed again.
Mozilla Firefox	Mozilla Firefox currently supports the native placeholder property and displays the ellipsis correctly, indicating that the placeholder text stretches beyond the field that is currently visible 
Whereas `sap.m.Input` contains just a single line placeholder, `sap.m.TextArea` is a multiline control, meaning it brings with it different issues to the ones listed above. These issues are different depending on the browser and are listed below.

Table 3: placeholder Property in sap.m.TextArea

Browser	Situation
Google Chrome	Google Chrome supports the native placeholder property and displays multiple lines along with a scrollbar Internet Explorer Version 11	Internet Explorer 11 supports the native placeholder property and displays multiple lines along with a scrollbar.  **i Note** Clicking the scrollbar sets focus from a technical perspective, meaning the placeholder text disappears and makes scrolling impossible. Scrolling with the mouse wheel does not set focus, and enables you to read the entire placeholder text.
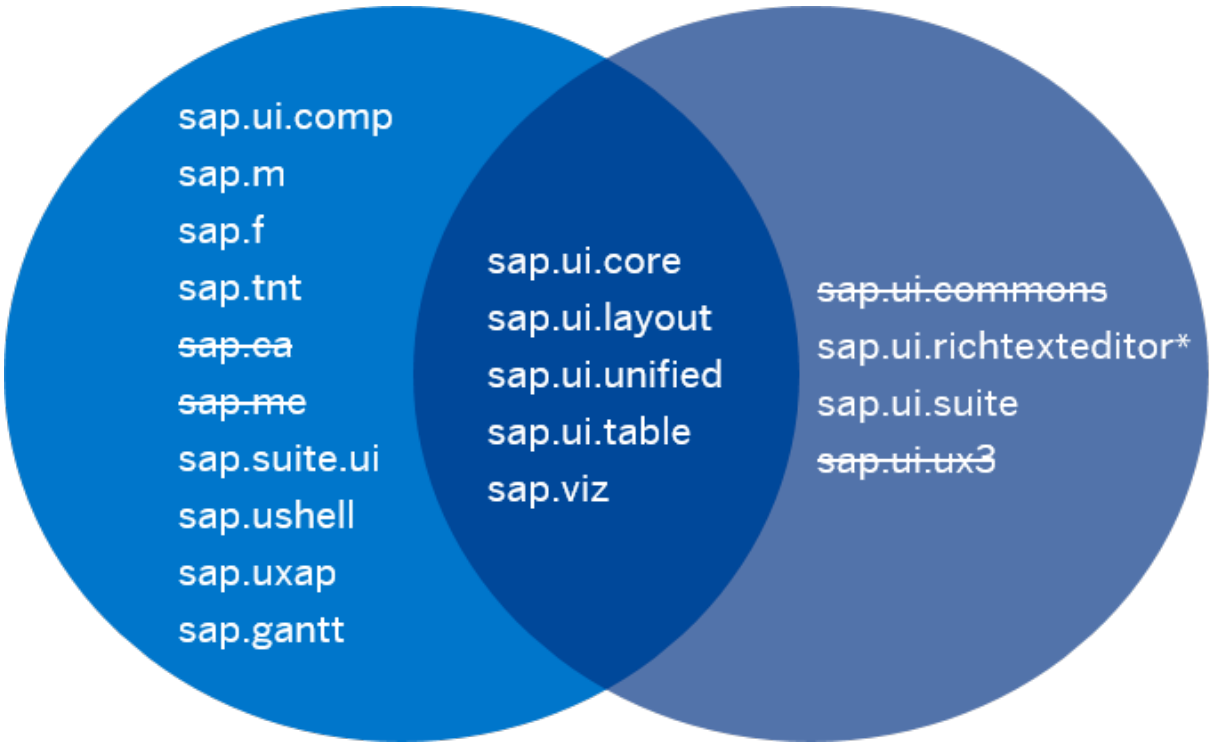
Mozilla Firefox	Mozilla Firefox supports the native placeholder property but does not display a scrollbar or an ellipsis, instead it simply truncates the placeholder text string 
Supported Library Combinations

SAPUI5 provides a set of JavaScript and CSS libraries, which can be combined in an application using the combinations that are supported.

There are two sets of possible library combinations, which are best described using the diagram below. Any of the libraries listed on the lefthand side can be used with those listed in the middle, and any of the libraries listed on the righthand side can be used with the ones listed in the middle. The libraries listed on the lefthand side **cannot** be used in combination with the libraries listed on the right, and vice versa:

i Note

Libraries that are not mentioned explicitly, belong to the lefthand side.



*Combinations between `sap.m` and `sap.ui.richtexteditor` are allowed only for desktop apps when using version 4 of TinyMCE.

Deprecated Themes and Libraries [page 34]

Supported Combinations of Themes and Libraries

This chapter gives an overview of the possible combinations of themes and libraries for the SAPUI5 versions that are still in maintenance.

Active Libraries

The following table shows which themes are available for the active SAPUI5 libraries. Even though the `sap_bluecrystal` and the `sap_hcb` themes are now deprecated, they currently are still available, but will not be maintained. We recommend that you migrate your existing apps to the supported themes.

Table 4: Themes for Supported Libraries

	1.38	1.44	1.46	1.65	1.69	1.74
`sap_fiori_3_dark`	n/a	n/a	n/a	n/a	n/a	■
`sap_fiori_3`	n/a	n/a	n/a	■	■	■
`sap_fiori_3_hcb` `sap_fiori_3_hcw`	n/a	n/a	n/a	n/a	■	■
`sap_belize` `sap_belize_plus`	n/a	■	■	■	■	■
`sap_belize_hcb` `sap_belize_hcw`	n/a	n/a	■	■	■	■
`sap_bluecrystal`	■	⚠	⚠	⚠	⚠	⚠
`sap_hcb`	■	■	⚠	⚠	⚠	⚠

■ = Supported, ⚠ = Not Supported

Deprecated Libraries

Should you decide to ignore the deprecation of libaries and continue, for example, using `sap.ui.commons` and `sap.ui.ux3`, we recommend you use the `sap_bluecrystal` or `sap_belize` theme.

The `sap_bluecrystal` theme is also no longer supported, but offers full coverage of the `sap.ui.commons` and the `sap.ui.ux3` library. It is currently still shipped, **but will be removed in one of the next versions.**

The `sap_belize` theme offers an initial implementation for the `sap.ui.commons` and the `sap.ui.ux3` library to allow for a smoother transition, but it is not supported for this library and will not be maintained. We recommend that you consider migrating your existing apps to actively developed libraries, such as `sap.m`, and use `sap_belize` as the default theme going forward.

Table 5: Themes for the Deprecated Libraries `sap.ui.commons` and `sap.ui.ux3`

	1.38	1.44	1.46	1.48	1.65
`sap_fiori_3`	n/a	n/a	n/a	n/a	
`sap_belize` `sap_belize_plus`	n/a				
`sap_belize_hcb` `sap_belize_hcw`	n/a	n/a			
`sap_bluecrystal`					
`sap_hcb`					
`sap_goldreflection`					
`sap_platinum`					
`sap_ux`					

= Supported, = Not Supported, = Deprecated, = Removed

Deprecated Themes and Libraries [page 34]

Versioning of SAPUI5

Versioning and maintenance strategy for SAPUI5.

SAPUI5 uses a 3-digit version identifier, for example 1.60.2. The digits have the following meaning:

- The first digit (1) specifies the release number (major version).
- The second digit (60) specifies the version number (minor version).
- The third digit (2) specifies the patch number.

To view the documentation for a specific version, check at https://ui5.sap.com/versionoverview.html which versions are available. You can view the version-specific Demo Kit by adding the version number to the URL, for example, `https://ui5.sap.com/1.60.2/`.

To get an overview of the new features of each version, see What's New in SAPUI5 [page 6], to see the fixes contained in each patch check the Change Log.

Maintenance Strategy

Every month, SAPUI5 releases a new version for productive usage:

- On SAP Cloud Platform, all SAPUI5 versions are shipped.
- On AS ABAP, only two SAPUI5 versions per year are shipped as part of the SAP_UI component.

The release strategy follows the principle of "one innovation code line": subsequent versions ensure continuous innovation with an evolving code line.

Once a year, a version with long-term support is released and available on both SAP platforms. This SAPUI5 version is included in a release of the SAP_UI component, usually as part of SP02 of the respective SAP_UI release. All other versions do not have a maintenance period and no patches are provided. Required fixes are available with the next minor versions together with the new features. However, in exceptional cases, also the most recent version may be patched with correction code.

For the decision to consume a new version, we recommend the following guideline:

- For SAP Cloud Platform, we recommend to upgrade to the latest available SAPUI5 version.
- For AS ABAP/SAP Fiori Frontend Server, or in case regular version updates are not feasible, we recommend to update to the respective long-term maintenance versions as outlined in the *Minimal Installation Requirements* and *SAP Fiori Frontend Server* notes.

For example, the following versions have a long-term maintenance:

- 1.38 which is included in SAP_UI 7.50 and UI add-on 2.0
- 1.44 which is included in SAP_UI 7.51
- 1.52 which is included in SAP_UI 7.52
- 1.60 which is included in SAP_UI 7.53

In the version overview at https://ui5.sap.com/versionoverview.html, you can see which of the SAPUI5 versions have an extended maintenance.

For more information on the SAPUI5 maintenance strategy for SAP NetWeaver AS for ABAP, see SAP Note 2217489.

Availability of Multiple Versions on the Akamai Content Delivery Network

All SAPUI5 resources are available on the content delivery network Akamai. There, you can also find multiple SAPUI5 versions, and you can use them in your code as described in Variant for Bootstrapping from Content Delivery Network [page 696].

Check the available versions with respective maintenance status at https://ui5.sap.com/versionoverview.html.

SAPUI5 Version vs. OpenUI5 Version (Core Version)

You can find which patch versions you use in you app in the technical information dialog (Ctrl + Left Alt + Shift + P).

The patch version number of the SAPUI5 version and the OpenUI5 version that is included, may be different.

OpenUI5 includes the core runtime libraries and some additional libraries.

To access the SAPUI5 version at runtime, you can use the following code:

```
sap.ui.require([
    "sap/ui/VersionInfo",
    "sap/base/util/Version"
], function(VersionInfo, VersionUtil) {
    VersionInfo.load().then(function(oCurrentVersionInfo) {
        var oVersionUtil = new VersionUtil(oCurrentVersionInfo.version);
        // ...
    });
});
```

To access the OpenUI5 version (core version) at runtime, you use the following code:

```
var oConfig = sap.ui.getCore().getConfiguration();
var oVersion = oConfig.getVersion();
```

For more information, see SAPUI5 vs. OpenUI5 [page 37].

Upgrading

The following sections describe what you have to consider when upgrading to a new version of SAPUI5.

Upgrading from a Version Below 1.40

Older jQuery Versions Removed

As of this version, SAPUI5 only contains one version of jQuery (the current version is 2.2.3). This standard version is always used when no other jQuery version is included in the bootstrap of an app. If you need a specific jQuery version for your app, add and load it explicitly as described in noJQuery Variant for Bootstrapping [page 698]. Check the console for the related warning message if you are unsure which version you are using.

Upgrading from a Version Below 1.38

When upgrading to the current SAPUI5 version from a version below 1.38 (released in June 2016), check whether the changes listed below influence your apps.

With this SAPUI5 version, jQuery has been upgraded to version 2.2.3.

This upgrade may impact your SAPUI5 apps. The following sections give an overview of our findings and how to deal with them.

> **i** Note
>
> If you use additional open-source libraries that depend on jQuery, check whether they need to be upgraded as well.

jQuery.Event

Problem

jQuery removed some robustness checks in its event handling code. Without these checks, the `jQuery.trigger` function must only be called with events that either have no `originalEvent` property or where the `originalEvent` has all methods that `window.Event implements` (especially `preventDefault`, `stopPropagation` and `stopImmediatePropagation`).

When a `jQuery.Event` is constructed with an object literal (`properties`) or when `originalEvent` is set to some object after construction, this constraint is not fulfilled. Unfortunately, many SAPUI5 unit tests used this approach to simulate mouse or key events.

Solution

For each code that creates events, you have to apply the following fix:

The module `QUnitUtils` now rewrites the `jQuery.Event` constructor so that any given object literal is enriched with the missing methods. Most SAPUI5 unit tests include the `QUnitUtils` module early, which then fixes the issue.

Application code that needs to simulate an event, either should omit the `originalEvent` or use `Event.create` to create a native event and only then create a `jQuery.Event`.

jQuery.fn.position

Problem

`jQuery.fn.position` now takes the scroll positions of the parent element into account. This change was recoginzed as incompatible by the jQuery team and reverted with version 2.2.1.

Solution

Nothing, this is automatically fixed.

jQuery.now

Problem

`jQuery.now` is now set to `Date.now` for all browsers. But as the jQuery property represents a separate reference to that function, it is not touched by code that modifies `Date.now`, especially not by Sinon fake timers. Therefore Sinon fake timers don't work with jQuery 2.2 if Sinon is started after `jQuery`.

Solution

As a workaround, `QUnitUtils` redefines `jQuery.now` so that it delegates to the current `Date.now`. This will then use any installed fake timer.

:visible selector

Problem

Somewhere between jQuery 1.11.1 and 2.2.0, the behavior of the `:visible` selector has changed. For empty inline elements (for example, a `span` with no text), the selector now reports `:visible = true` whereas jQuery 1.1.1 reported it as `hidden`. There was only one functionality in the `sap.ui.dt` library where this change in behavior caused problems.

Solution

Instead of using `:visible`, that functionality now uses its own implementation similar to jQuery 1.11.1.

Sizzle attribute selector ([name=value])

Problem

In Microsoft Internet Explorer, the attribute selector no longer works when the attribute value is unquoted and starts with a hash (`#`). This is the case when hash-name-references are searched for, like with the `usemap` attribute of the `IMG` element.

Solution

Use quotes (`""`) for attribute values in those cases.

jQuery.isPlainObject

Problem

jQuery 2.2.0 simplified the implementation of `jQuery.isPlainObject`. As a side-effect, objects with a `constructor` property with a non-function value (like a `string` value) caused a runtime error when `jQuery.isPlainObject` was applied.

Solution

This issue is fixed with jQuery 2.2.2.

Descriptor for Applications, Components, and Libraries

If you want to add new attributes of a descriptor version higher than V2 (SAPUI5 1.30) to your existing `manifest.json` file, see Migration Information for Upgrading the Descriptor File [page 775].

Deprecated Themes and Libraries

As SAPUI5 evolves over time, some of the UI controls are replaced by others, or their concepts abandoned entirely. This chapter gives an overview on theme and library level of the most important deprecations. Individual control deprecations and more information about the controls replacing them can be found in the API reference within the Demo Kit.

Themes that are no longer supported

sap_hcb

The `sap_hcb` theme is deprecated as of version 1.48. It has been replaced by the `sap_belize_hcb` theme.

`sap_hcb` is the High Contrast Black theme used for the already deprecated `sap_goldreflection` and `sap_bluecrystal` themes. For `sap_belize` and `sap_belize_plus` there are two high contrast themes available: `sap_belize_hcb` (High Contrast Black) and `sap_belize_hcw` (High Contrast White).

sap_bluecrystal

The `sap_bluecrystal` theme is no longer supported as of version 1.40. It has been replaced by `sap_belize` as the default theme for SAPUI5 applications.

Custom themes based on `sap_bluecrystal` are no longer supported with 1.40 or higher.

sap_ux

The `sap_ux` theme is no longer supported as of version 1.40. This was one of the very first SAPUI5 themes and is only implemented by a small subset of the `sap.ui.commons` and `sap.ui.ux3` controls, which are also deprecated.This theme has been removed with SAPUI5 version 1.48.

sap_platinum

The `sap_platinum` theme is no longer supported as of version 1.40. This was one of the very first SAPUI5 themes and is only implemented by a small subset of the `sap.ui.commons` and `sap.ui.ux3` controls, which are also deprecated. This theme has been removed with SAPUI5 version 1.48.

sap_goldreflection

The `sap_goldreflection` theme is no longer supported as of version 1.40. This was one of the first SAPUI5 themes and is only implemented by the `sap.ui.commons` and `sap.ui.ux3` controls, which are also deprecated. This theme has been removed with SAPUI5 version 1.48.

Deprecated Libraries

sap.ui.commons

The `sap.ui.commons` library is deprecated as of version 1.38.

`sap.ui.commons` was available from the very beginning of SAPUI5. It contains a large number of basic UI controls like buttons, input fields and dropdowns. With version 1.16, the `sap.m` library was introduced. It contains semantically identical controls (button, input and select) that, at that time, were only supported on mobile platforms. In later versions, `sap.m` was extended to support desktop platforms as well. For more information about this, see Browser and Platform Support [page 20]. The `sap.m` controls were bigger in size to support mobile displays that require a larger touch area. The "Compact Content Density" feature explained under Content Densities [page 1142] was then added to SAPUI5, allowing you to display a control in a more compact screen size. Today, applications should be built one single time using `sap.m` (and other libraries) and their content density switched at runtime depending on the environment. As such, the redundant library `sap.ui.commons` should no longer be used.

Some of the controls in `sap.ui.commons.layout` have been replaced by the new dedicated layout library called `sap.ui.layout`, which runs on the same platforms as `sap.m`.

Some of the old controls have been made available again through the non-deprecated `sap.ui.unified` library (e.g. FileUploader, Menu), which runs on the same platforms as `sap.m`.

Some concepts such as Accordion and Row Repeater have been abandoned completely.

sap.ui.ux3

The `sap.ui.ux3` library is deprecated as of version 1.38.

This library contains more complex UI controls that were based on `sap.ui.commons` along the UX3 design approach. The `sap.m` library - successor to `sap.ui.commons` - implements SAP's new SAP Fiori design [http://experience.sap.com/fiori-design/], which supersedes UX3. As such, the `sap.ui.ux3` library is also deprecated. Some of the UX3 concepts are reflected in SAP Fiori, some are abandoned, as outlined in the following table:

Concept	What's Happened?
Feeds	Replaced by sap.m (`sap.m.Feed*`).
Notification Bar	Replaced by sap.m (`sap.m.MessagePopover` and `sap.m.semantic*`).
Thing Inspector	Indirectly replaced by a different design for displaying object data.

Concept	What's Happened?
Shell	Partially replaced by `sap.ui.unified.Shell`.
Data Set	Not part of SAP Fiori.
Exact	Not directly part of SAP Fiori. Use `sap.ui.comp.FilterBar` or `sap.m.IconTabBar` for filtering.
Quick Views	Concept abandoned as the concept of "hovering with the mouse pointer over a control" does not exist on mobile devices.

For more information about the SAP Fiori design, see the SAP Fiori design guidelines.

sap.ca

The `sap.ca` library is deprecated as of version 1.22.

This library contains a mixture of controls for various use cases. Some were replaced by `sap.m` (e.g. DatePicker, Message) and some were discontinued without being replaced (such as Hierarchy or OverflowContainer).

sap.me

The `sap.me` library is deprecated as of version 1.34.

The main feature within the `sap.me` library are the calendar controls. You find replacement controls in the `sap.ui.unified` library covering most but not all features of the `sap.me` calendars.

sap.makit

The `sap.makit` library is deprecated as of version 1.38.

The `sap.makit` library contains a few chart controls that only support mobile platforms and do not support accessibility measures. This library is replaced by `sap.viz`.

Supported Combinations of Themes and Libraries [page 27]

SAPUI5 vs. OpenUI5

With SAPUI5 and OpenUI5 we provide two deliveries of our UI development toolkit. Both are very closely related, but have their differences.

Licenses

The main difference is the license.

OpenUI5 is Open Source, free to use, released under the Apache 2.0 license. Since we also use many Open Source libraries, we try to return the favor and also benefit from the experience and knowledge of developers all over the world.

SAPUI5 is not a separate SAP product with a separate license. It's integrated, for example, in the following products:

- SAP HANA
- SAP Cloud Platform
- SAP NetWeaver 7.4 or higher (included in the UI technologies (`SAP_UI`) component)
- User interface add-on for SAP NetWeaver Application Server 7.3x

Content

The easiest way to get an overview of which libraries are delivered is to have a look at the *API Reference* of the each Demo Kit. You'll see that the list of libraries in SAPUI5 is much longer... which in no way means that OpenUI5 provides just a very limited scope!

Most importantly, the core containing all central functionality and the most commonly used control libraries is identical in both deliveries. (For example, `sap.m`, `sap.ui.layout`, `sap.ui.unified`.)

So OpenUI5 also gives you all the important features needed to build feature-rich Web applications.

The additional libraries in SAPUI5 include more controls on top, like charts, and SAPUI5 also lets you use 'smart controls', for example, which are controls that are automatically configured by OData annotations from the back end. The exact feature range of SAPUI5 also depends on the platform you're using. For example, you can only use the ABAP repository with SAP NetWeaver and not on SAP Cloud Platform.

Contributing to OpenUI5

OpenUI5 is Open Source, and is available on GitHub .

If you find a bug or have an idea for a new feature - just go ahead and propose a GitHub issue or a change. But before you do so, please just read our guidelines first: Contributing to OpenUI5 .

Resources

For the OpenUI5 version, visit http://openui5.org/ where you can download the runtime and the Demo Kit (SDK) at http://openui5.org/download.html.

For the SAPUI5 resources, check your platform installation.

Both resources are also available online via the content delivery network provider Akamai at `https://openui5.hana.ondemand.com/` and `https://sapui5.hana.ondemand.com/`.

Compatibility of OpenUI5 and SAPUI5

Technically, you can switch between OpenUI5 and SAPUI5 (providing you have the respective license), e.g. if you want to use the SAPUI5-specific features.

Just check first which SAPUI5 version you need, because the version numbers of OpenUI5 and SAPUI5 might differ on patch level (last number). You can find this information in the technical information dialog (`Ctrl` + `Alt` + `Shift` + `P`).

If you're using the content delivery network, you can simply replace the bootstrapping reference to `https://openui5.hana.ondemand.com/<1.xx.yy>/` with a reference to `https://sapui5.hana.ondemand.com/<1.xx.zz>/`. For more information, see Variant for Bootstrapping from Content Delivery Network [page 696].

For all other cases, replace the runtime. Since the technical names (of controls, libraries, etc.) and APIs are the same in both OpenUI5 and SAPUI5, the code will still work and you can start enhancing it directly.

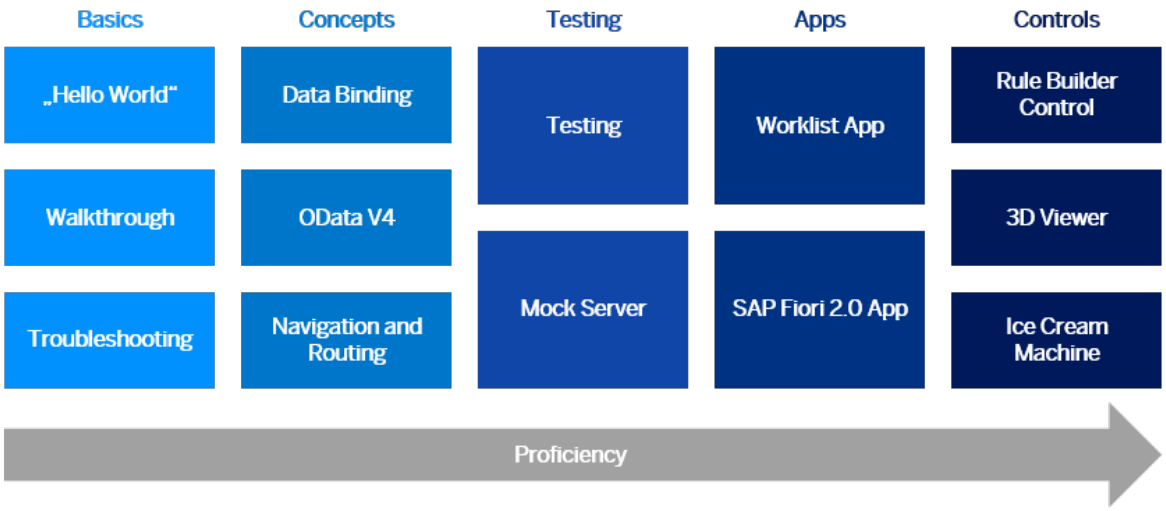
Get Started: Setup, Tutorials, and Demo Apps

Set up your development environment and go through our tutorials. They introduce you to all major development paradigms of SAPUI5 using practical examples in an interactive format. The demo apps show SAPUI5 in action.

Prerequisites and Setup

- You should be familiar with JavaScript.
- Set up your development environment: Get SAPUI5 and place it in a location, which can be accessed in the resources folder (not necessary for SAP Web IDE). For more information, see Development Environment [page 41].
- Set up a folder where you would place the application content. We will refer to this folder as the “app folder”.

Learning Path



- Quick Start [page 57]
- Walkthrough [page 69]
- Troubleshooting [page 194]
- Data Binding [page 219]
- OData V4 [page 261]
- Navigation and Routing [page 291]
- Testing [page 368]
- Mock Server [page 432]
- Worklist App [page 447]
- SAP Fiori 2.0 App [page 488]
- 3D Viewer [page 607]
- Rule Builder Control [page 536]
- Ice Cream Machine [page 640]

→ Tip

Learn with openSAP:

The openSAP course Developing Web Apps with SAPUI5 introduces you to the main concepts of SAPUI5.

The JavaScript exercises for each unit will give you the technical background needed to develop your own responsive Web apps. We'll start from scratch with the very basics and lots of hands-on coding. As we go through the weeks of this course, you'll learn more about the powerful development concepts and truly master SAPUI5.

The openSAP course Evolved Web Apps with SAPUI5 for more experienced SAPUI5 developers and ambitious beginners introduces more advanced scenarios and concepts.

Downloading Code for a Tutorial Step

To download the code from the Demo Kit, follow these steps:

1. Choose the link in the *Coding* section of the tutorial step you want to work on or find the code in the *Samples* section of the Demo Kit (filter by "*Tutorial*" to get a list of the tutorials that are available).
2. Choose the icon with the *Show source code for this sample* tooltip in the right-hand part of the header bar to display all files included in this sample.
3. Choose the *Download* button. A `zip` file is downloaded to your local machine.
4. Extract or upload the `zip` file to your development environment.
5. Adjust the project configuration files to match your development environment as described below.
6. Test the project by calling one of the HTML pages in your development environment and make sure that the app is displaying the features exactly as shown in the preview of the step.

Adapting Code to Your Development Environment

You might have to adapt parts of the coding to your local development environment to make the app work. Please check the following settings carefully:

- **Project Path and Deployment**
  All tutorials assume that the app is deployed and can be accessed under a certain path on a web server. You will not be able to run the app without a Web server as the browser does not allow you to load the required resources locally due to security restrictions.
- **SAPUI5 Resources**
  You can either download and deploy the runtime to your (local) Web server or reference the CDN version located at `https://sapui5.hana.ondemand.com/resources/sap-ui-core.js`. Some development environments such as the SAP Web IDE also provide a local runtime for testing purposes. If you download the code from the samples in the Demo Kit, you will have to adapt the **resource path in the bootstrap section** of all HTML pages included in the project. In the tutorial code, we assume that SAPUI5 can be accessed from the `/resources` path of the server.
- **Accessing Remote Services**
  Browsers typically prevent accessing remote resources due to the Cross-Origin Resource Sharing (CORS) policy. If you would like to call a real service or remote resources, you will have to either configure the development environment or the remote server to accept these requests. This strongly depends on the development environment and is described in more detail below.

Troubleshooting

If you get stuck, check the Troubleshooting [page 1314] section under *Essentials*, or refer to the Troubleshooting tutorial [page 194].

If you can't fix the problem, try downloading the solution of the previews or current step. This should get your project fixed again, just don't forget to check the resource path and the project configuration files again.

See SAPUI5 in Action - Our Demo Apps

If you want to see some practical examples for SAPUI5 apps, check out our Demo Appsour *Demo Apps* section in the Demo Kit. These are fully-functional apps that showcase certain floorplans, control libraries, or other SAPUI5 features. You can also download the source code of each demo app to find out how everything works together. Feel free to explore!

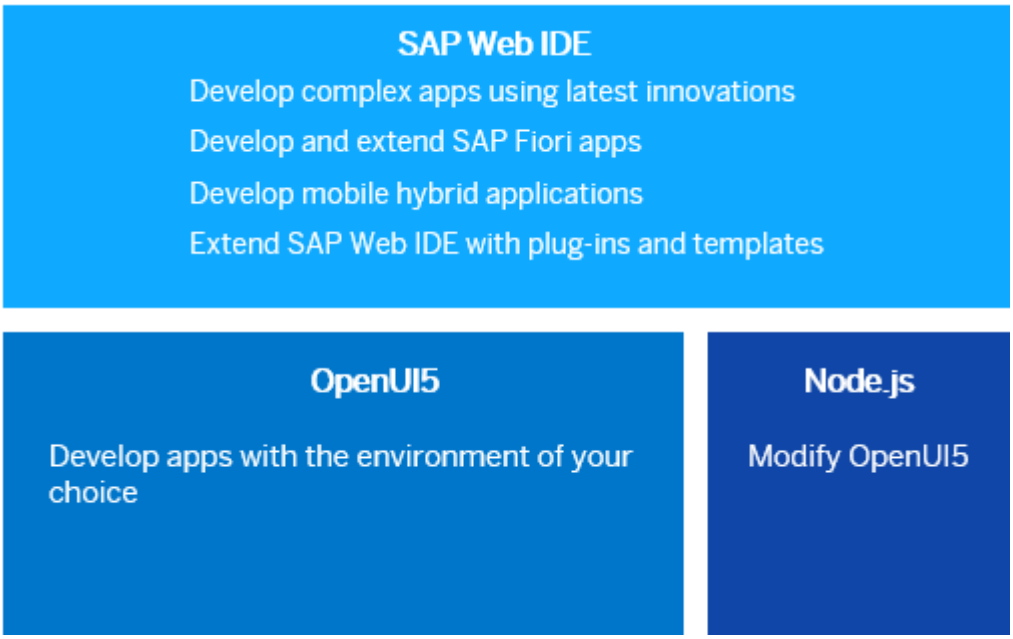
Development Environment

This part of the documentation gives you guidance on the most common and recommended use cases of the installation, configuration, and setup of the SAPUI5 development environment.

> **i** Note
>
> You can use SAPUI5 on different platforms. The license and maintenance conditions of the respective platforms also apply for SAPUI5. If you use SAPUI5 tools on SAP Cloud Platform, for example, the license and maintenance conditions of the SAP Cloud Platform apply.

Depending on your use case, you can choose one of the following development environments.



- App Development Using SAP Web IDE [page 44]
- App Development Using OpenUI5 [page 42]
- Developing OpenUI5 [page 51]

> **i** Note
>
> The SAPUI5 Tools for Eclipse as a development environment are no longer supported with SAPUI5 versions after 1.71. For more information, see SAPUI5 Tools for Eclipse – Now is the Time to Look for Alternatives. If you are using the SAPUI5 Tools for Eclipse with SAPUI5 version 1.71 or earlier, please consult the documentation for your specific SAPUI5 version.

App Development Using OpenUI5

Develop apps using OpenUI5 and the development environment (editor and Web server) of your choice. You can either download all of the sources or refer to the online version of OpenUI5.

Download OpenUI5

The default way of downloading and installing OpenUI5 is to get the runtime from the OpenUI5 website at http://openui5.org and deploy it on a Web server.

1. Go to https://openui5.org/releases/ and choose *Download Stable Release* to download a ZIP file containing the current stable release of the OpenUI5 sources.

2. Unzip this file and put the entire content on the Web server where your application is running (or you can even package it within your application to deploy it along with the app).
3. In your app's main HTML file, load OpenUI5 by referring to the `resources/sap-ui-core.js` file that was contained in the ZIP file. (See Standard Variant for Bootstrapping [page 694].)

Using OpenUI5 Sources from a Content Delivery Network

If you don't want to download the files and don't want to include them in your deployment, you can use the online version of OpenUI5. For more information, see Variant for Bootstrapping from Content Delivery Network [page 696].

> **i Note**
>
> You can find a list of all available OpenUI5 versions here: https://openui5.hana.ondemand.com/versionoverview.html.
>
> Only use the *Stable* version for productive apps. Nevertheless, if you also want to test the *Nightly* version, you are very welcome to send us your feedback!

Consume OpenUI5 Using the Node Package Manager

You can also use the node package manager (npm) to develop your applications. For this, you need to add the OpenUI5 dependencies to your package.json file:

```
{
  ...
  "dependencies": {
    "@openui5/sap.m": "^1.60.0",
    "@openui5/sap.ui.core": "^1.60.0",
    "@openui5/sap.ui.layout": "^1.60.0",
    "@openui5/themelib_sap_belize": "^1.60.0"
  },
  ...
}
```

To install single dependencies for your application via npm, simply run the npm install command from your terminal:

```
npm install @openui5/sap.ui.core @openui5/themelib_sap_belize [...]
```

You can find a sample application, which uses this mechanism and describes its usage, on GitHub at https://github.com/SAP/openui5-sample-app .

For more information on how to use npm and how to serve your application based on these packages, see the UI5 tooling documentation on GitHub at https://sap.github.io/ui5-tooling/ .

App Development Using SAP Web IDE

SAP Web IDE is a web-based development environment that is optimized for developing SAPUI5 complex apps using the latest innovations, developing and extending SAP Fiori apps, developing mobile hybrid apps, and extending SAP Web IDE with plug-ins and templates.

Key use cases:

- Develop new SAP Fiori apps and SAPUI5 apps
- Extend SAP Fiori apps
- Develop SAPUI5 mobile hybrid apps (HAT plug-in)
- Extend SAP Web IDE with new plug-ins and templates

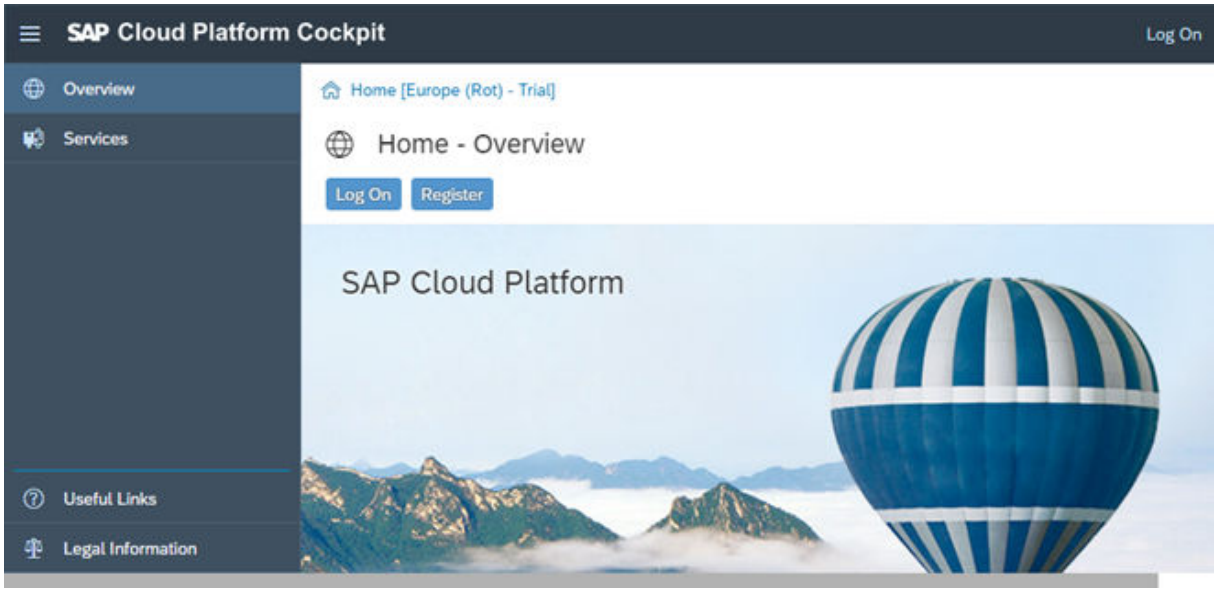
A trial version of SAP Web IDE can be accessed through the SAP Cloud Platform.

For more information about SAP Web IDE, see the documentation for SAP Web IDE on the SAP Help Portal at https://help.sap.com/viewer/p/SAP_Web_IDE.

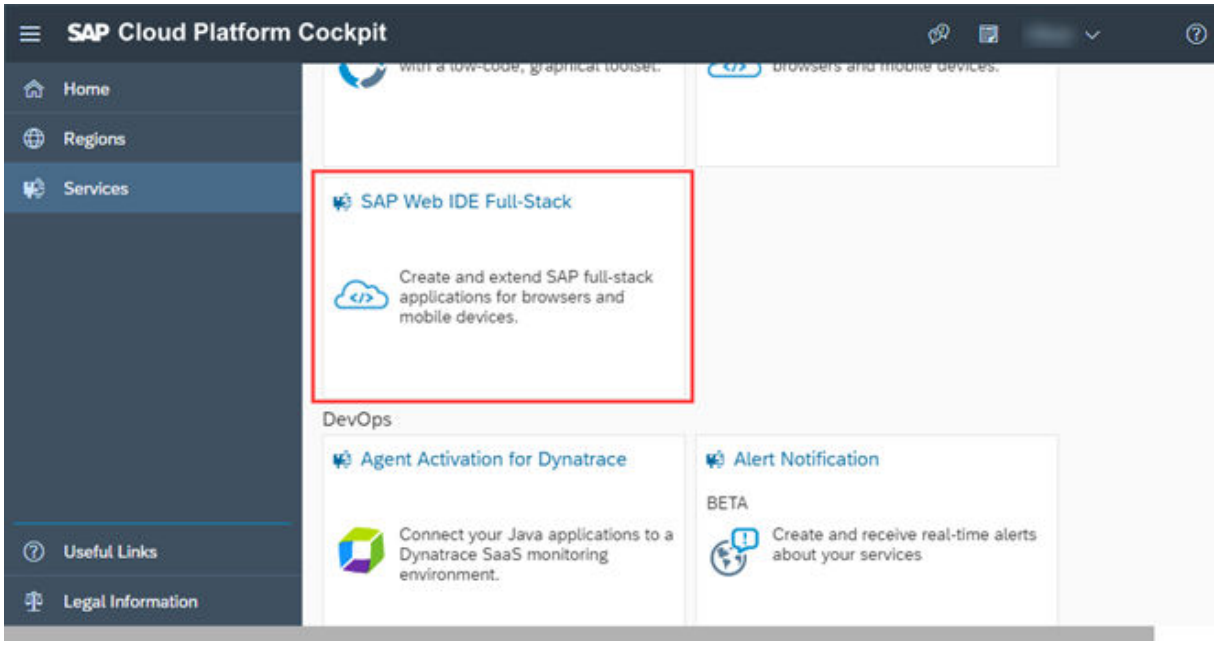
Get a Trial Account and Access SAP Web IDE

Steps for creating an SAP Cloud Platform trial account

If you do not have access to SAP Web IDE, you can create a free account. To create an account, simply register an SAP Cloud Platform trial account at https://account.hanatrial.ondemand.com/, and log on afterwards.



After you have logged on, choose *Services* in the navigation bar of the SAP Cloud Platform cockpit, and open the detailed information on your SAP Web IDE by choosing the SAP Web IDE Full-Stack tile.



> **i** Note
>
> Do **not** choose the simple SAP Web IDE tile (without "Full-Stack" in the title), because this service is not longer available for our purposes.

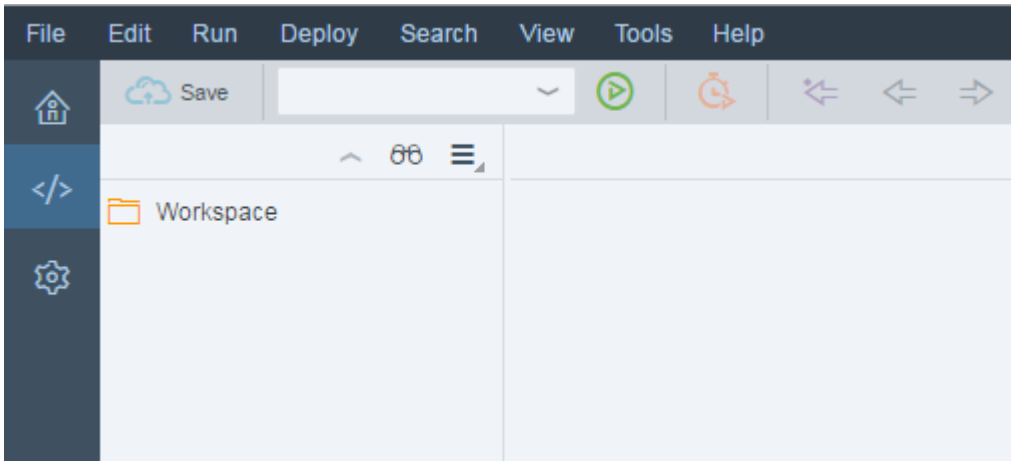
Selecting *Go to Service* leads you to your personal SAP Web IDE.

> **→** Tip
>
> You can bookmark this link to access SAP Web IDE later.

Start SAP Web IDE

Initial Steps in SAP Web IDE

1. Open SAP Web IDE and wait until the initialization has finished.
   When you start it for the first time, you will see a home screen containing more information about SAP Web IDE.
2. Change to the *Development* perspective by clicking the icon with the code symbol on the left sidebar.
   You now see a folder list with an entry *Workspace* on the left side and an empty code editor on the right side.



3. Create your project within the *Workspace* folder by choosing *File* > *New* > *Folder* from the menu or `Ctrl` + `Alt` + `Shift` + `N`. Enter, for example, **`myProject`** as the folder name.

Create a neo-app.json Project Configuration File

The `neo-app.json` file contains all project settings for SAP Web IDE and is created in the root folder of your project. It is a JSON format file consisting of multiple configuration keys. The most important setting for you to configure is the path where the SAPUI5 runtime is located when starting the app.

You do this using the “routes” key and defining an array of resource objects. For running an SAPUI5 tutorial, you only need two entries - one that configures SAPUI5 to be available with the path `/resources`, and another one that configures the test resources needed for the SAP Fiori launchpad integration with the path `/test-resources`.

Create two configuration objects that contain a `path`, a `target`, and a `description` attribute with more configuration settings. The `path` and the `entryPath` values will point to the location on the server where the SAPUI5 resources will be stored.

SAP Web IDE reads these settings automatically when running the app. You can see the whole configuration file in the code block below. Optionally, you can add the key `welcomeFile` to configure the entry point to your app. In web applications, this is typically the `index.html` file.

> **i Note**
>
> Depending on which SAP Web IDE version you are using, you might have to configure the project to run against the "snapshot" version of SAPUI5, otherwise the application will be launched with the SAPUI5 release that is delivered with SAP Web IDE. This is usually the latest version that is released publicly to customers.
>
> You can check which version of SAPUI5 is loaded by opening the SAPUI5 debugging tools with `CTRL` + `SHIFT` + `ALT` + `P`. If the version is too old for certain features of the tutorial, you have to add the `version` attribute to the target configuration entry and set the value to `snapshot`.

Procedure

1. Select the *New File* icon and enter **`neo-app.json`** as the file name.
2. Open the newly created file from the tree structure on the left side of the screen.
3. Paste the following code in the `neo-app.json` and select *Save*:

```
{
  "welcomeFile": "index.html",
  "routes": [
    {
      "path": "/resources",
      "target": {
        "type": "service",
        "name": "sapui5",
        "version": "snapshot",
        "entryPath": "/resources"
      },
      "description": "SAPUI5 Resources"
    },
    {
      "path": "/test-resources",
      "target": {
        "type": "service",
        "name": "sapui5",
        "entryPath": "/test-resources"
      },
      "description": "SAPUI5 Test Resources"
    }
  ]
}
```

Create an index.html File

A minimalistic `index.html` file is needed to test the project configuration. This file contains the SAPUI5 bootstrap and an `sap.m.Text` control that displays the text "**SAPUI5 is loaded successfully!**".

1. Choose the *New Folder* icon in the header toolbar and enter **`src`** as the folder name.
2. Select the newly created folder and create a new `index.html` file inside it by choosing the *New File* icon.
3. Paste the following code in the newly created `index.html` file and select *Save*:
   index.html

```
<!DOCTYPE html>
<html>
    <head>
        <meta http-equiv="X-UA-Compatible" content="IE=edge">
        <meta charset="utf-8">
        <title>SAPUI5 Walkthrough</title>
        <script
            id="sap-ui-bootstrap"
            src="/resources/sap-ui-core.js"
            data-sap-ui-theme="sap_belize"
            data-sap-ui-libs="sap.m"
            data-sap-ui-compatVersion="edge"
               data-sap-ui-async="true"
               data-sap-ui-onInit="module:my/app/main"
               data-sap-ui-resourceRoots='{"my.app": "./"}'
             ></script>
```

```
    </head>
    <body class="sapUiBody" id="content">
    </body>
</html>
```

4. Create new file `main.js` and paste the following code into it:
   main.js

```
sap.ui.define(['sap/m/Text'], function(Text) {
    new Text({
        text: "OpenUI5 is loaded successfully!"
    }).placeAt("content");
});
```

> ⚠ Caution
>
> Adapt the path where the resources are located (`src="/resources/sap-ui-core.js"`) according to your installation. For OpenUI5 you can use `src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"`. For accessing SAPUI5 on the SAP Cloud Platform, for example, use `src="https://sapui5.hana.ondemand.com/resources/sap-ui-core.js"`.
>
> You can use this reference to the latest stable version of SAPUI5 for the tutorial or for testing purposes, but never use this for productive use. In an actual app, you always have to specify an SAPUI5 version explicitly.
>
> For more information, see Variant for Bootstrapping from Content Delivery Network [page 696].

Run the App

SAP Web IDE comes with integrated testing features that let you run the app on a central server without having to set up any additional infrastructure. You can run the app by selecting the `src/index.html` file and clicking the *run* button in the header toolbar.

This launches the app on a central server and a testing tool that allows you to configure the screen size and orientation of the device. This feature can be used to test apps that are specifically targeted for mobile, tablet, and desktop devices. You can change the resolution and the orientation in the header bar very easily.

If you don't want to run the app in the testing tool, you can adjust the *Run Configurations* for the project:

1. Right-click any file in the project and select *Run* > *Run Configurations*.
2. Choose + and select *Web Application* to add a new run configuration.
3. To save the configuration and run your project, choose *Save and Run*.

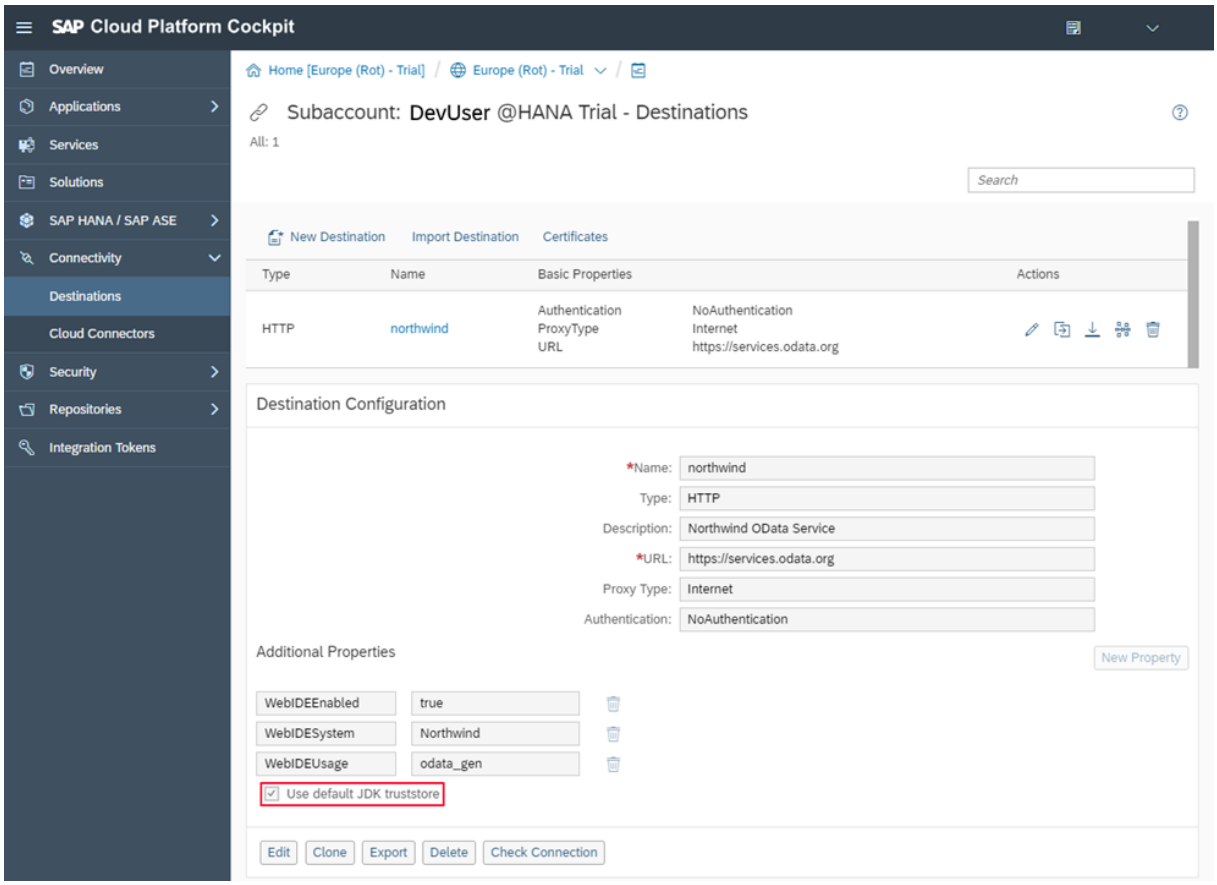
For more information on how to run projects, search for *Configuring How to Run Projects* in the SAP Web IDE Developer Guide for the SAP Cloud Platform on the SAP Help Portal at https://help.sap.com/viewer/p/CP.

Create a Northwind Destination

Configure a destination in the SAP Cloud Platform Cockpit in order to bypass the same-origin policy of the browser.

To be able to test your app, you can use a remote OData service that provides product data from the Northwind demo service of the OData group.

In the navigation bar of the SAP Cloud Platform Cockpit, choose *Destinations* and then choose *New Destination* in the toolbar.



Enter the following values into the corresponding fields:

Field	Value
Name	`northwind`
Type	`HTTP`
Description	`Northwind OData Service`
URL	`https://services.odata.org`
Proxy Type	`Internet`

Field	Value
Authentication	**NoAuthentication**

Also, enter the following properties in the section *Additional Properties*:

Property	Value
`WebIDEEnabled`	**true**
`WebIDESystem`	**Northwind**
`WebIDEUsage`	**odata_gen**
`Use default JDK truststore`	Set the checkmark.

neo-app.json

With this configuration you can use the destination for any app inside SAP Web IDE. Whenever an app calls a (local) service beginning with `/destinations/northwind/*`, the created destination becomes active as a simple proxy. This helps to prevent any possible issues related to the same-origin policy of browsers. For this, you need to add another route to the `neo-app.json`:

```
{
  "welcomeFile": "index.html",
  "routes": [
    {

      "path": "/resources",
      "target": {
        "type": "service",
        "name": "sapui5",
        "version": "snapshot",
        "entryPath": "/resources"
      },
      "description": "SAPUI5 Resources"
    },
    {
      "path": "/test-resources",
      "target": {
        "type": "service",
        "name": "sapui5",
        "entryPath": "/test-resources"
      },
      "description": "SAPUI5 Test Resources"
    },
    {
      "path": "/destinations/northwind",
      "target": {
        "type": "destination",
        "name": "northwind"
      },
      "description": "Northwind OData Service"
    }
  ]
```

```
}
```

webapp/manifest.json

In the app descriptor, the service URL is then defined relative to the destination path specified above:

```
...
"sap.app": {
 "dataSources": {
   "": {
     "uri": "/destinations/northwind/V2/Northwind/Northwind.svc/",
     "type": "OData",
     "settings": {
       "odataVersion": "2.0"
     }
   }
 }
}
...
```

Developing OpenUI5

This section provides information for the initial setup, development workflow, and how tests are executed.

Setting Up the OpenUI5 Development Environment

OpenUI5 content is developed in an environment based on Node.js. UI5 Tooling is used as development server and build tool.

Basic Setup

The basic setup allows you to start a server for the OpenUI5 project in an easy way:

1. Install Node.js. This also includes npm, the node package manager.
2. Clone the OpenUI5 Git repository. You can download and install Git from http://git-scm.com/download :

   ```
   git clone https://github.com/SAP/openui5.git
   ```
3. Install all npm dependencies. Optionally, you can also use Yarn for this. This is described in the Advanced Setup section.

   ```
   cd openui5
   npm install
   ```
4. Start the server and open the TestSuite:

   ```
   npm run testsuite
   ```

To just start the server, enter:

```
npm start
```

5. Your default browser should open automatically and show the TestSuite: You're done!

Configuring the TestSuite Server

The OpenUI5 TestSuite server can be configured using environment variables. For example, to allow remote access to the server, that is, from an interface other than your computer's loopback/localhost, you can configure the server as follows:

```
OPENUI5_SRV_ACC_RMT_CON=true npm start
```

The following server configuration is available:

- `OPENUI5_SRV_OPEN=index.html`
- `OPENUI5_SRV_ACC_RMT_CON=true`
- `OPENUI5_SRV_PORT=9090`

Advanced Setup

The basic setup described above uses a custom setup focused on starting the UI5 server for the OpenUI5 TestSuite project in an easy way.

The advanced setup allows you to use the UI5 CLI and all of its features. The use of Yarn is required in this setup, as npm cannot handle workspaces yet.

Use the advanced setup if you plan to do any of the following:

- Build an OpenUI5 project.
- Serve a project with HTTPS or HTTP/2.
- Use any of the other UI5 CLI features and parameters.

For the advanced setup, proceed as follows:

1. Install the UI5 Tooling CLI globally, seeUI5 Tooling: Installing the UI5 CLI .
2. Install Yarn. See FAQ: What's the thing with Yarn? .
3. In the OpenUI5 repository root directory, install all dependencies using Yarn. This also links all OpenUI5 libraries between each other.

   ```
   yarn
   ```

4. Navigate into the TestSuite project and start the UI5 server:

   ```
   cd src/testsuite
   ui5 serve --open index.html
   ```

You can now use the UI5 CLI in any of your local OpenUI5 libraries. Whenever you make changes to your OpenUI5 repository's `node_modules` directory (e.g. by executing `npm install`), you may need to recreate the links between the OpenUI5 libraries. You can always do this by executing `yarn` in the OpenUI5 root directory.

Legacy Setup

You can continue to use the legacy Grunt-based setup. However, the setups described above are recommended for working with the OpenUI5 repository.

To use the legacy setup, execute `npm run start-grunt`. Note that in the past this was the default `npm start` behavior.

The legacy setup has the following differences to the standard setups as described above:

- `testsuite` path prefix:
  Standard setup: `http://localhost:8080/test-resources/testsuite/testframe.html`
  Legacy setup: `http://localhost:8080/testsuite/test-resources/testsuite/testframe.html`
- SDK documentation generated by `grunt docs` can only be served using the legacy setup.

The Development Process

For a regular development, no build is required. Just modify any source file and reload your browser. Now that's simple, isn't it?

This build-free development process does not feature optimized runtime performance. For example, there are many small requests, which would not be acceptable for remote connections. But it is the most convenient way to modify the OpenUI5 sources. Under the hood there are mainly two mechanisms applied that adapt the sources:

- The Git repository path contains a folder named like the respective control library (e.g. "sap.m"), which is omitted at runtime. The UI5 CLI server is mapping the locations.
- The CSS files are transformed (server-side) by the LESS pre-processor during the first request after a CSS file has been modified. This includes mirroring for right-to-left support.

When you work on OpenUI5 applications or libraries that already make use of the OpenUI5 npm packages, such as the OpenUI5 sample app, you can link your local OpenUI5 repository into that project. This allows you to make changes to the project itself as well as to the OpenUI5 libraries simultaneously and test them immediately.

For a detailed step-by-step guide on how to achieve such a setup with the OpenUI5 sample app, see Working With Local Dependencies .

Building OpenUI5

The UI5 Tooling is used to build a production-ready version of OpenUI5. Every library needs to be built individually.

Usage:

```
ui5 build
```

The build is responsible for the following tasks:

- Creation of the bundled `library.css` and `library-RTL.css` file for all available themes
- Minification of CSS
- Minification of JavaScript
- Bundling the JavaScript modules of the libraries into a single `library-preload.js` file
- Bundling of the most important OpenUI5 Core modules into `sap-ui-core.js`

If you encounter errors like the one below, execute `yarn` in the OpenUI5 root directory. There may be new build tools required which need to be downloaded first.

```
Error: Cannot find module 'xyz'
```

Testing OpenUI5

All OpenUI5 code must conform to a certain ruleset which is checked with ESLint.

To run an ESLint check, navigate to the root directory of the repository and execute:

```
npm run lint
```

Running Tests

Tests can be executed automatically with the Karma Test-Runner.

To run tests of a library, the `--lib` needs to be passed. The `<library-name>` corresponds to the folder within `./src/`, e.g. `sap.m`.

```
npm run karma -- --lib=<library-name>
```

This executes all tests of that library in watch mode, which will automatically re-run tests in case of file changes.

Example

```
npm run karma -- --lib=sap.m
```

Running a Specific Test

Instead of executing all tests of a library, you can also only run one test or a testsuite.

To find the URL, open `http://localhost:8080/test.html` and search for the test. Copy the URL and remove the origin part (`http://localhost:8080/`), so that it starts with `resources` or `test-resources`.

```
npm run karma -- --lib=<library-name> --ui5.testpage="<testpage-url>"
```

> **i** Note
>
> The corresponding `--lib` option still needs to be provided accordingly.

Example

```
npm run karma -- --lib=sap.m --ui5.testpage="resources/sap/ui/test/starter/
Test.qunit.html?testsuite=test-resources/sap/m/qunit/
testsuite.mobile.qunit&test=Button"
```

Coverage

You enable coverage reporting by additionally passing the `--coverage` option:

```
npm run karma -- --lib=<library-name> --coverage
```

Continuous integration (CI)

You enable the continuous integration mode by additionally passing the `--ci` option. This enables Chrome headless and disables the watch mode, so the execution stops after all tests have been executed:

```
npm run karma -- --lib=<library-name> --ci
```

You can combine the options `--ci` and `--coverage`.

Development for Hybrid Web Containers

You can develop mobile apps as hybrid app consisting of a native app wrapper, for example PhoneGap, and an HTML viewer to display the content on the user interface.

Hybrid apps have the advantage that you can publish them in app stores. Also, by embedding the application code and the SAPUI5 library files into the hybrid container, the user needs to install the files only once and does **not** need to download them every time he starts the application. But then the library size becomes important, because every user has to install the files, whereas in web applications, the library is deployed on a server and the user only needs to download the required parts of the library at runtime.

To include the resources you need in your hybrid app, you can use the static mobile runtime package `openui5-runtime-mobile*.zip`. The package is **not** contained in SAPUI5, but in the Open Source version OpenUI5.

The library size of these packages is rather small because the content that is most likely not needed has been removed, for example test pages. A package contains the debug version of all JavaScript files and the optimized and minimized version. Thus, you can use the package for productive use as well as for debugging purposes. To use this package in an app wrapper, such as PhoneGap, unzip the package in the respective resource location of the app development project. The app wrapper build then includes the files and makes them available at runtime.

To ensure that the file is small, it only contains the control libraries that are most likely used and not all control libraries. Depending on the hybrid app it may be necessary to add libraries by copying them from the respective folder of the runtime, or to delete libraries to reduce the package size and, thus, also reduce the installation size for the user.

The file contains the following control libraries:

- `sap.f`
- `sap.m`
- `sap.tnt`
- `sap.ui.core`
- `sap.ui.layout`
- `sap.ui.suite`
- `sap.ui.unified`
- `sap.uxap`

The decision, which libraries to include or not may be disputed. It is only based on a rule of thumb, and adaptations are required anyway for many apps.

Also, the mobile/hybrid package excludes certain types of files which are typically not needed. Your mileage may vary, so you might need to add the respective files for the requirements of your specific app. The

`library-preload.js` files which contain all controls from a library to reduce the number of HTTP requests are not required in hybrid apps because there is no HTTP latency. SAPUI5 will by default try to access them, so you might see a failed attempt to load these files in the log file or developer tools. These error messages do not hurt, though, and you can get rid of them by declaring that no such files exist and by setting the following configuration in the SAPUI5 bootstrap script tag:

```
data-sap-ui-preload=""
```

Optimization of the Package Size

Although the static package is small enough to be included in hybrid apps, you can reduce the size further and optimize the content for a specific application by deleting additional files. The following list gives some examples:

- You can delete all library folders if the respective control library is not needed. For example, in the OpenUI5 version you can delete the `suite` and the `unified` folder.
- In each of the `/resources/sap/* ... */themes` folders, you can delete all theme folders except the one for the theme you are using.

> **i Note**
>
> For all JavaScript files, an optimized version and a debug (`dbg`) version exists. If you delete the files, make sure that you always delete both versions. If you can do without easy debugging and want to achieve a minimum installation size, we recommend to delete all `*-dbg.js` files.

You can delete further files, but the size reduction is limited and to find out the files that are not required gets increasingly difficult.

Device Ready Event

The hybrid web container needs some time for initialization. During this time, the sending of AJAX requests is blocked, meaning that JavaScript code stops once an AJAX request is sent and the code execution stops as well. This leads to a UI freeze effect.

The OData model in SAPUI5 uses AJAX requests internally and the OData model initialization must therefore be done after the hybrid container is ready to avoid a user interface freeze. After initialization, the hybrid web containers fires an event, which is called `deviceready` in PhoneGap. To fix this issue, move the code where the OData model is created and set to the core object or any other controls' model property to the `deviceready` event listener.

Example:

```
<script>
<!-- put the following code in the beginning of the application code -->
function appReady(){
    sap.ui.getCore().setModel(new sap.ui.model.odata.v2.ODataModel(<ODATA_URL>));
}
<!-- bind to the deviceready event -->
document.addEventListener("deviceready", appReady, false);
```

```
</script>
```

Cross Domain Restrictions

If you load data from an external server or service using AJAX, the external domain has to be configured inside the hybrid web container to make the AJAX request go through the cross domain restriction. The following findings result from an integration of the demo applications into PhoneGap:

- Android
  If the AJAX code runs inside the webview in Android, no cross domain restriction exists. This means that you can load data using AJAX from everywhere. The PhoneGap documentation, however, still says that the domain needs to be configured in one XML file.
- iOS
  The restriction in webview in iOS still exists and you need to add the domain that is visited using AJAX to a whitelist file to bypass the restriction. For detailed information about the whitelist file, see the PhoneGap documentation on the PhoneGap website.

Quick Start

Unleash your SAPUI5 skills with this simple three-step tutorial. We start with a simple "Hello World" example, and convert it to a minimalist two-page app.

We create an app with two pages and a navigation button to navigate between the pages.

Preview

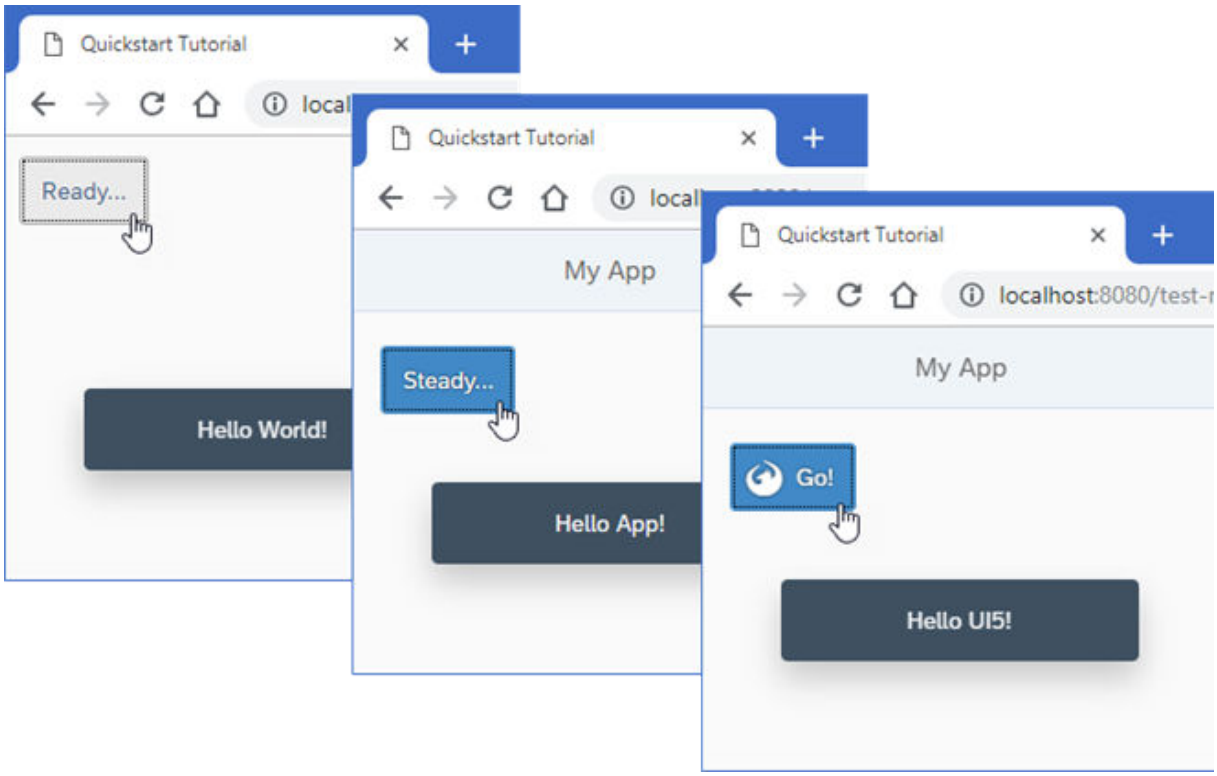


Figure 1: Ready...Steady...Go!

> → Tip
>
> If you want to skip one or more steps, you can jump directly to the step you're interested in. Then simply download the code from the previous step, and start learning from there. You can download the code for each step in the the Quick Start Sample.

> i Note
>
> All you need to build your app, is a Web browser and a development environment of your choice. For more information, see the links below.

Related Information

Development Environment [page 41]

Step 1: Ready...

Let's get you ready for your journey! We bootstrap SAPUI5 in an HTML page and implement a simple "Hello World" example.

Preview

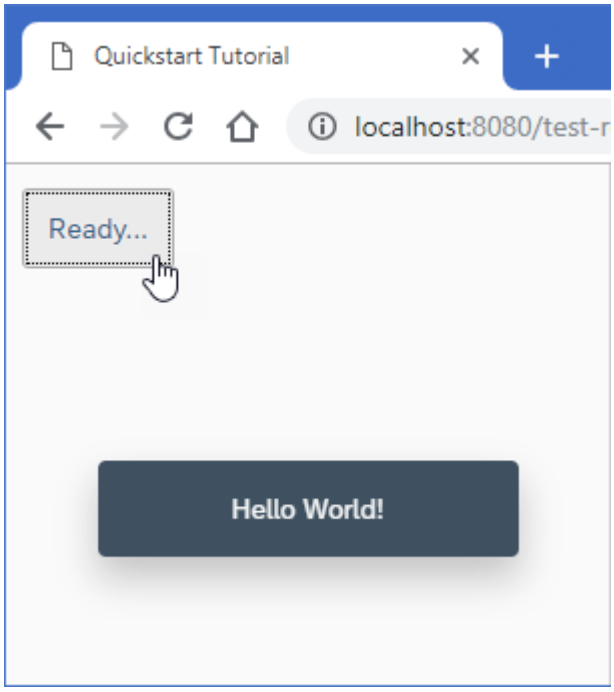

Figure 2: The browser shows a "Ready" button that triggers a "Hello World" message

Coding

You can view and download all files at Quick Start - Step 1.

webapp/index.html (new)

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <title>Quickstart Tutorial</title>
    <script id="sap-ui-bootstrap"
        src="../../../../../../../../resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-libs="sap.m"
        data-sap-ui-resourceroots='{"Quickstart": "./"}'
        data-sap-ui-onInit="module:Quickstart/index"
```

```
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true">
    </script>
</head>
<body class="sapUiBody" id="content"></body>
</html>
```

In your development environment (SAP Web IDE is recommended), create the folder `webapp`. In this folder, create an `index.html` file, and paste the above code to this file.

With the `script` tag, we load and initialize SAPUI5 with typical bootstrap parameters. We define, for example, a theme, control libraries, as well as performance and compatibility flags.

First, we need a source to load SAPUI5 from. To keep things convenient, we use the path to our Content Delivery Network (CDN) for OpenUI5.

The bootstrap property `resourceroots` defines the namespace for all resources of the app. This way, we can easily reference additional files that we are about to create in this step.

The `index` module that we load with the `onInit` parameter will hold the application logic.

The `body` tag is defined with the `sapUiBody` class and the `content` ID. This is where we will add the content of the app in the next steps.

> → Tip
>
> For more information about bootstrapping from the CDN, see Variant for Bootstrapping from Content Delivery Network [page 696].

webapp/index.js (New)

```
sap.ui.define([
    "sap/m/Button",
    "sap/m/MessageToast"
], function (Button, MessageToast) {
    "use strict";

    new Button({
        text: "Ready...",
        press: function () {
            MessageToast.show("Hello World!");
        }
    }).placeAt("content");

});
```

In your `webapp` folder, create a new file `index.js` that will be called as soon as SAPUI5 is loaded and initialized.

We load two UI controls - a button and a message toast - and place the button in the element with the `content` ID. The button is defined with a `text` property and a callback attached to its `press` event.

Now open the `index.html` file in your browser. When the button is pressed, a message toast with the "Hello World" message is shown at the bottom of the screen.

neo-app.json (new, optional)

> **i** Note
>
> This file is necessary if you use SAP Web IDE as your development environment. It contains all project settings and is located in the root folder of your project. This file is **not** part of the downloadable code in the Demo Kit, so just copy the content from here.

```
{
  "welcomeFile": "/webapp/index.html",
  "routes": [
    {
      "path": "/resources",
      "target": {
        "type": "application",
        "name": "sapui5preview",
        "entryPath": "/resources"
      },
      "description": "SAPUI5 Resources"
    },
    {
      "path": "/resources",
      "target": {
        "type": "service",
        "name": "sapui5",
        "entryPath": "/resources"
      },
      "description": "SAPUI5 Resources"
    }
  ],
  "sendWelcomeFileRedirect": true
}
```

Create a neo-app.json Project Configuration File [page 46]
Variant for Bootstrapping from Content Delivery Network [page 696]

Step 2: Steady...

Now we extend our minimalist HTML page to a basic app with a view and a controller.

Preview

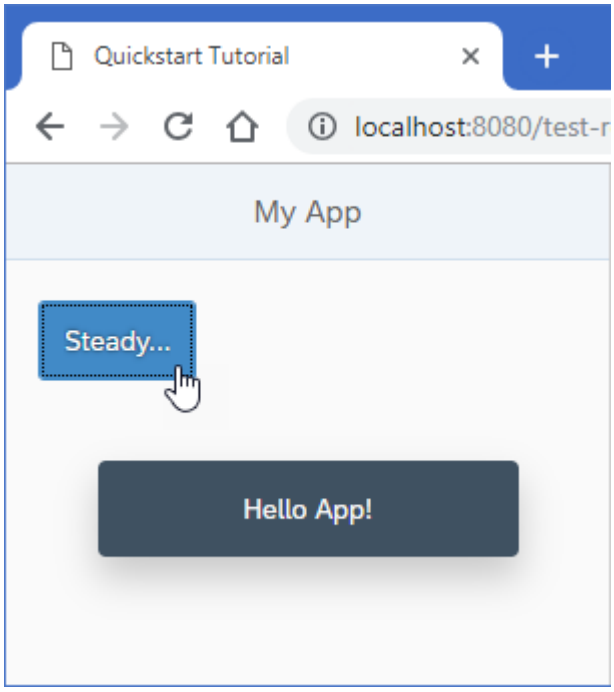

Figure 3: The browser shows a *Steady* button in an app

Coding

You can view and download all files at Quick Start - Step 2.

webapp/index.js

```
sap.ui.define([
    "sap/ui/core/mvc/XMLView"
], function (XMLView) {
    "use strict";
    XMLView.create({viewName: "Quickstart.App"}).then(function (oView) {
        oView.placeAt("content");
    });
});
```

Now we replace most of the code in this file: We remove the inline button from the previous step, and introduce a proper XML view to separate the presentation from the controller logic. We prefix the view name `Quickstart.App` with our newly defined namespace. The view is loaded asynchronously.

Similar to the step before, the view is placed in the element with the `content` ID after it has finished loading.

webapp/App.view.xml (New)

```
<mvc:View
    controllerName="Quickstart.App"
    displayBlock="true"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <App>
        <Page title="My App">
            <Button
                text="Steady..."
                press=".onPress"
                type="Emphasized"
                class="sapUiSmallMargin"/>
        </Page>
    </App>
</mvc:View>
```

The presentation logic is now defined declaratively in an XML view.

UI controls are located in libraries that we define in the `View` tag. In our case, we use the bread-and-butter controls from `sap.m`.

The new controls in the view are an `App` and a `Page`. They define a Web app with a header bar and a title.

The button from the previous examples now also defines a `type` and a `class` attribute. This improves the layout of our button and makes it stand out more.

We outsource the controller logic to an app controller. The `.onPress` event now references a function in the controller.

webapp/App.controller.js (New)

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageToast"
], function (Controller, MessageToast) {
    "use strict";

    return Controller.extend("Quickstart.App", {
        onPress : function () {
            MessageToast.show("Hello App!");
        }
    });

});
```

In our controller, we load the `Controller` base class and extend it to define the behavior of our app. We also add the event handler for our button.

The `MessageToast` is also loaded as a dependency. When the button is pressed, we now display a "Hello App" message.

Now reload your `index.html` file. You can see a title bar and a blue button that reacts to your input. Congratulations, you have created our very first app.

Related Information

XML View [page 787]
Controller [page 807]

Step 3: Go!

Finally, we add a second page to our app showcasing some of the key SAPUI5 concepts.

Preview

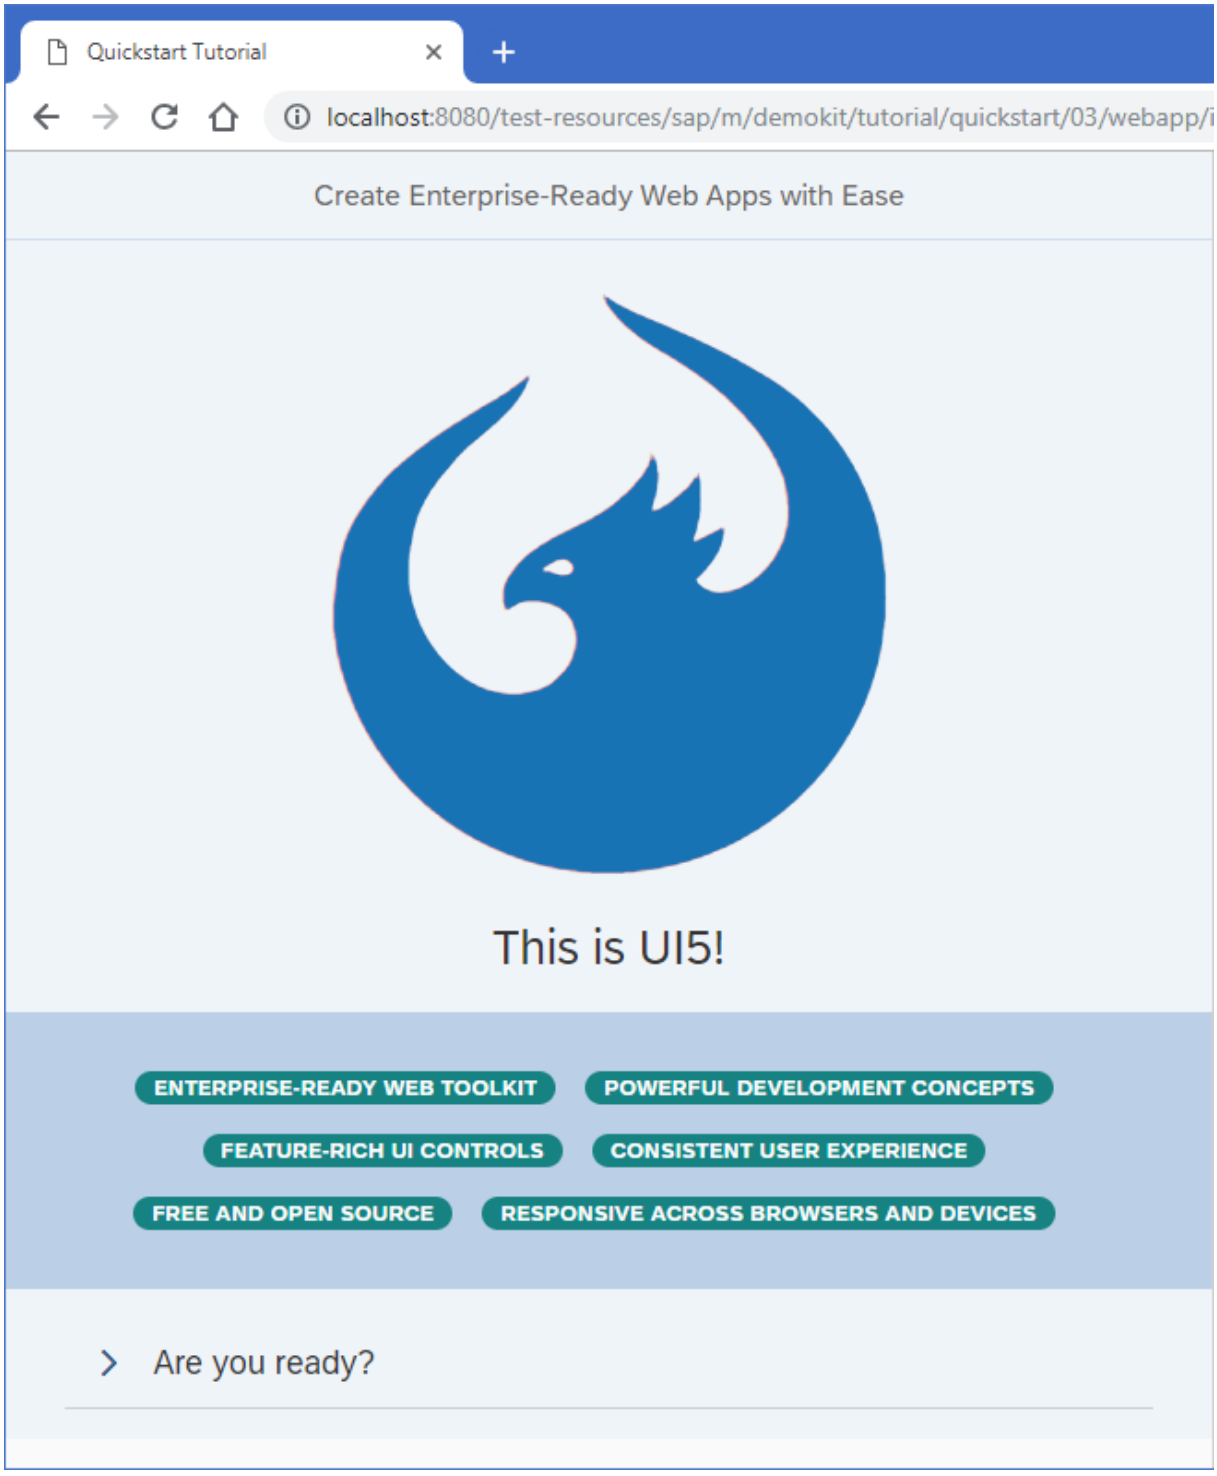

Figure 4: The second page shows plenty of UI controls and concepts to explore

Coding

You can view and download all files at Quick Start - Step 3.

webapp/index.html

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <title>Quickstart Tutorial</title>
    <script id="sap-ui-bootstrap"
        src="../../../../../../../../resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-libs="sap.m, sap.ui.layout, sap.tnt"
        data-sap-ui-resourceroots='{"Quickstart": "./"}'
        data-sap-ui-onInit="module:Quickstart/index"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true">
    </script>
</head>
<body class="sapUiBody" id="content"></body>
</html>
```

Let's spice up our app by adding some more UI controls. We add two more libraries in the bootstrap tag: `sap.ui.layout` and `sap.tnt`.

> → Tip
>
> To browse all available controls and libraries, see the Samples.

webapp/App.view.xml

```
<mvc:View
    controllerName="Quickstart.App"
    displayBlock="true"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:l="sap.ui.layout"
    xmlns:core="sap.ui.core"
    xmlns:tnt="sap.tnt">
    <App id="app">
        <Page title="My App">
            <Button
                icon="sap-icon://sap-ui5"
                text="Go!"
                press=".onPress"
                type="Emphasized"
                class="sapUiSmallMargin"/>
        </Page>
        <Page id="intro" title="Create Enterprise-Ready Web Apps with Ease">
            <l:BlockLayout background="Light">
                <l:BlockLayoutRow>
                    <l:BlockLayoutCell>
                        <core:Icon color="#1873B4" src="sap-icon://sap-ui5"
size="20rem" class="sapUiMediumMarginBottom" width="100%"/>
                        <Title level="H1" titleStyle="H1" text="This is UI5!"
width="100%" textAlign="Center"/>
                    </l:BlockLayoutCell>
                </l:BlockLayoutRow>
                <l:BlockLayoutRow>
                    <l:BlockLayoutCell>
                        <FlexBox items="{/features}" justifyContent="Center"
```

```
wrap="Wrap" class="sapUiSmallMarginBottom">
                            <tnt:InfoLabel text="{}" class="sapUiSmallMarginTop
sapUiSmallMarginEnd"/>
                        </FlexBox>
                    </l:BlockLayoutCell>
                </l:BlockLayoutRow>

                <l:BlockLayoutRow>
                    <l:BlockLayoutCell>
                        <Panel headerText="Are you ready?" expandable="true">
                            <Switch change=".onChange" customTextOn="yes"
customTextOff="no"/>
                            <l:HorizontalLayout id="ready" visible="false"
class="sapUiSmallMargin">
                                <Text text="Ok, let's get you started!"
class="sapUiTinyMarginEnd"/>
                                <Link text="Learn more" href="https://
openui5.hana.ondemand.com/"/>
                            </l:HorizontalLayout>
                        </Panel>
                    </l:BlockLayoutCell>
                </l:BlockLayoutRow>
            </l:BlockLayout>
        </Page>
    </App>
</mvc:View>
```

We also define the two new libraries in the `View` tag and give them a meaningful prefix. To the `App` control, we will assign an ID so that the controller can easily identify it.

The button now receives an icon and triggers our navigation to page two. Therefore, we change the text to "Go!".

Copy the second `Page` control with all its content into the view. It is defined with the `intro` ID and a new title. It contains several new UI controls like a `BlockLayout`, an `Icon`, and a `Panel`.

We use essential SAPUI5 concepts like navigation, data binding, and user interaction to define a nice playground on the second page of our app.

Don't worry too much about the details, we will explain them in the next tutorials.

webapp/App.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageToast",
    "sap/ui/model/json/JSONModel"
], function (Controller, MessageToast, JSONModel) {
    "use strict";
    return Controller.extend("Quickstart.App", {
        onPress : function () {
            MessageToast.show("Hello UI5!");
            this.byId("app").to(this.byId("intro"));
        },

        onInit : function () {
            this.getView().setModel(new JSONModel({
                    features: [
                        "Enterprise-Ready Web Toolkit",
                        "Powerful Development Concepts",
                        "Feature-Rich UI Controls",
```

```
                        "Consistent User Experience",
                        "Free and Open Source",
                        "Responsive Across Browsers and Devices"
                    ]
                })
            );
        },

        onChange: function (oEvent) {
            var bState = oEvent.getParameter("state");
            this.byId("ready").setVisible(bState);
        }
    });
});
```

The `onPress` function now also triggers the navigation to the `intro` page. We fetch the `app` control by its ID and instruct it to navigate by calling the `to` method.

The `onInit` method is a lifecycle hook that is called automatically when the controller is initialized. It defines a simple JSON model with some texts located at the `features` key.

We display these texts on the second page using data binding. The `InfoLabel` tag from our view is a template that is repeated as many times as we have entries in our model.

Finally, we make the Panel in the lower part of the view interactive by attaching an `onChange` event to the switch defined there. SAPUI5 comes with a large set of feature-rich controls that you can combine as you need.

Run the app, and navigate to the second page to see some nice UI controls and interaction. If we expand the panel and click the switch, we toggle the visibility of the text and the link next to it.

You now have a little playground in your app that you can modify and extend as you wish. We intentionally did not go into all the details. If you want to know more, just continue with the Walkthrough tutorial.

Have fun with SAPUI5!

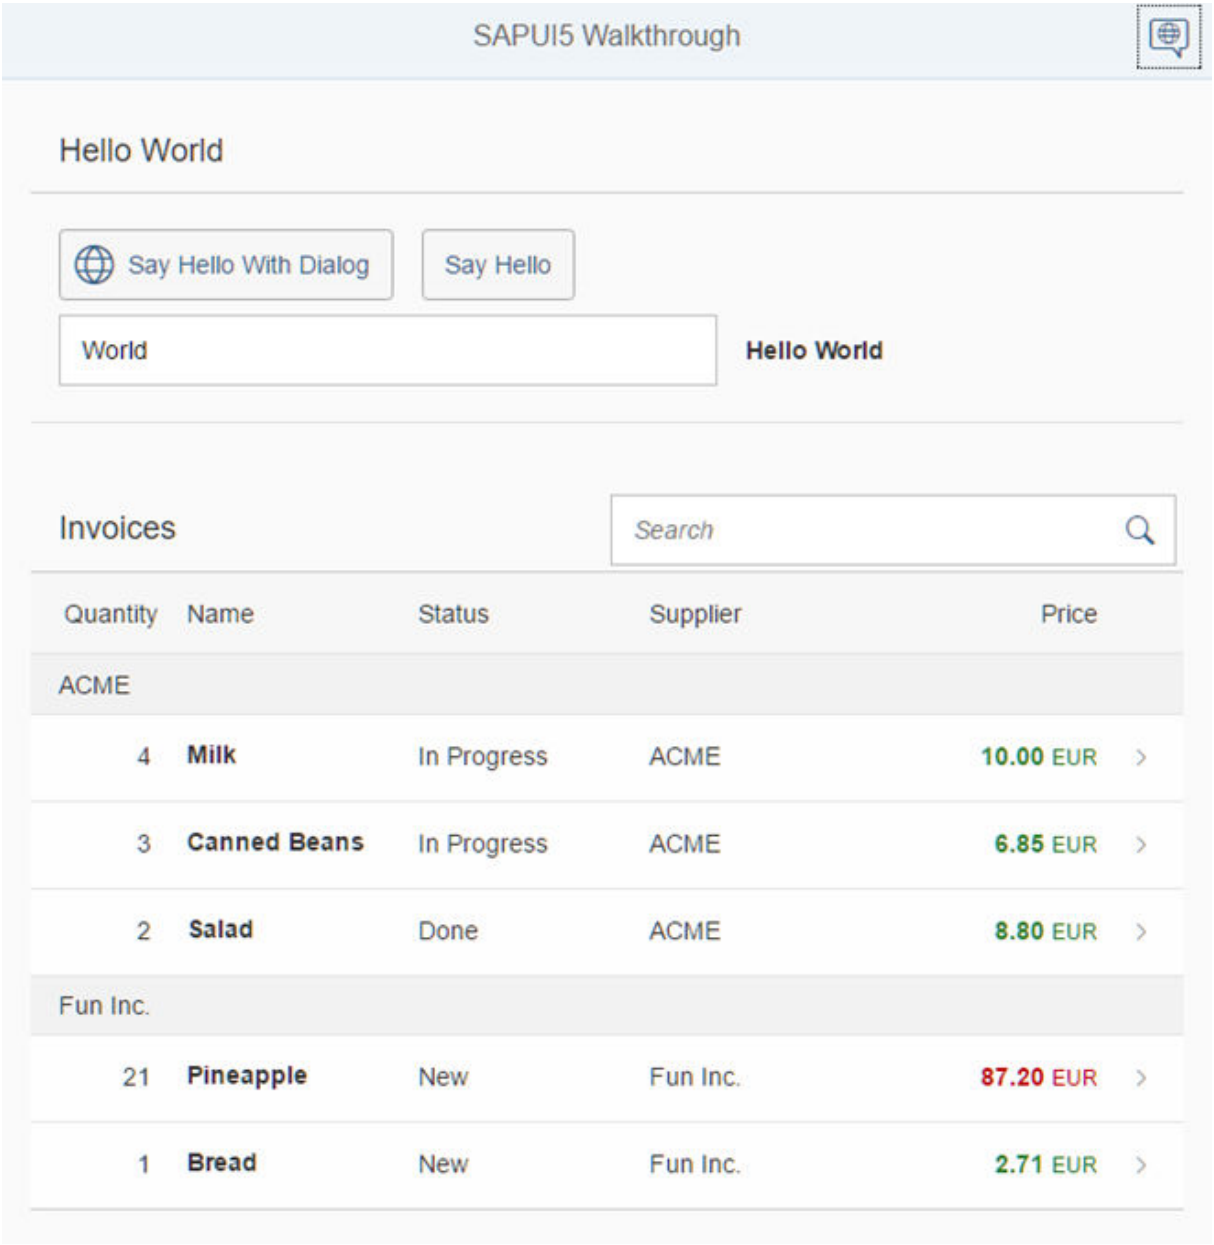
Walkthrough

In this tutorial we will introduce you to all major development paradigms of SAPUI5.

We first introduce you to the basic development paradigms like *Model-View-Controller* and establish a best-practice structure of our application. We'll do this along the classic example of “Hello World” and start a new app from scratch. Next, we'll introduce the fundamental data binding concepts of SAPUI5 and extend our app to show a list of invoices. We'll continue to add more functionality by adding navigation, extending controls, and making our app responsive.Finally we'll look at the testing features and the built-in support tools of SAPUI5.

Preview



→ Tip

You don't have to do all tutorial steps sequentially, you can also jump directly to any step you want. Just download the code from the previous step, copy it to your workspace and make sure that the application runs by calling the `webapp/index.html` file.

You can view and download the samples for all steps in the in the Demo Kit at Walkthrough. Depending on your development environment you might have to adjust resource paths and configuration entries.

For more information check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]

Step 1: Hello World!

As you know SAPUI5 is all about HTML5. Let's get started with building a first "Hello World" with only HTML.

Preview

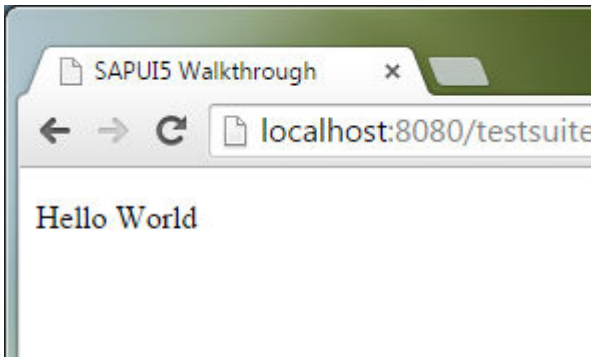


Figure 5: The browser shows the text "Hello World"

Coding

You can view and download all files at Walkthrough - Step 1.

webapp/index.html (New)

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <title>SAPUI5 Walkthrough</title>
</head>
<body>
    <div>Hello World</div>
</body>
</html>
```

Create a new folder `webapp` which will contain all sources of the app we will create throughout this tutorial. Therefore, we refer to this folder as "app folder".

Now create a new root HTML file called `index.html` in your app folder. An HTML document consists basically of two sections: head and body. The head part will be used by the browser to process the document. Using meta tags we can influence the behavior of the browser.

In this case we will tell the browser to use `UTF-8` as the document character set. We will also give our app a title that will be displayed in the browser. Be aware that our hard-coded title can be overruled by the app, for example to show a title in the language of the user.

The body part describes the layout of the page. In our case we simply display “Hello World” by using a `p` tag.

> → Tip
>
> Typically, the content of the `webapp` folder is deployed to a Web server as an application package. When deploying the `webapp` folder itself the URL for accessing the `index.html` file contains `webapp` in the path.

Conventions

- Name the root HTML file of the app `index.html` and locate it in the `webapp` folder.

Step 2: Bootstrap

Before we can do something with SAPUI5, we need to load and initialize it. This process of loading and initializing SAPUI5 is called **bootstrapping**. Once this bootstrapping is finished, we simply display an alert.

Preview

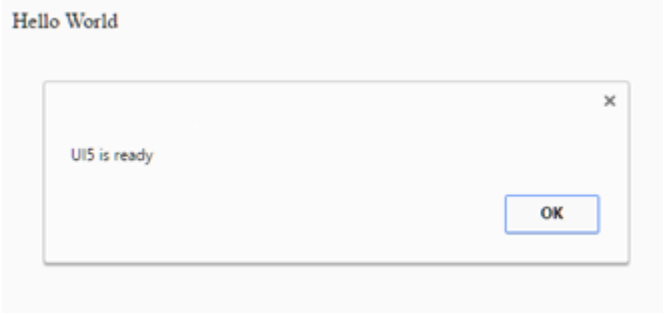

Figure 6: An alert "UI5 is ready" is displayed

Coding

You can view and download all files at Walkthrough - Step 2.

> i Note
>
> SAPUI5 is a JavaScript library that can either be loaded from the same Web server where the app resides, or from a different server. If SAPUI5 is deployed somewhere else on the server or you want to use a different server, then you need to adjust the corresponding paths in the bootstrap (here: `src="/resources/sap-ui-core.js"`) in this tutorial according to your own requirements.

You can use this reference to the latest stable version of SAPUI5 for the tutorial or for testing purposes, but never use this for productive use. In an actual app, you always have to specify an SAPUI5 version explicitly.

For more information about the CDN, see Variant for Bootstrapping from Content Delivery Network [page 696].

In case you are using SAP Web IDE, you can right-click the project and select *New* > *HTML5 Application Descriptor* to make the `/resources...` reference work. This creates the `neo-app.json` file, which configures a URL mapping for this path.

webapp/index.html

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <title>SAPUI5 Walkthrough</title>
    <script
        id="sap-ui-bootstrap"
        src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-libs="sap.m"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true"
        data-sap-ui-onInit="module:sap/ui/demo/walkthrough/index"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.walkthrough": "./"
        }'>

    </script>
</head>
<body>
<div>Hello World</div>
</body>
</html>
```

In this step, we load the SAPUI5 framework from our local webserver and initialize the core modules with the following configuration options:

- The `src` attribute of the `<script>` tag tells the browser where to find the SAPUI5 core library – it initializes the SAPUI5 runtime and loads additional resources, such as the libraries specified in the `data-sap-ui-libs` attribute.
- The SAPUI5 controls support different themes, we choose `sap_belize` as our default theme.
- We specify the required UI library `sap.m` containing the UI controls we need for this tutorial.
- To make use of the most recent functionality of SAPUI5 we define the compatibility version as `edge`.
- We configure the process of “bootstrapping” to run asynchronously.
  This means that the SAPUI5 resources can be loaded simultaneously in the background for performance reasons.
- We define the module to be loaded initially in a declarative way. With this, we avoid directly executable JavaScript code in the HTML file. This makes your app more secure. We will create the script that this references to further down in this step.
- We tell SAPUI5 core that resources in the `sap.ui.demo.walkthrough` namespace are located in the same folder as `index.html`. This is, for example, necessary for apps that run in the SAP Fiori launchpad.

webapp/index.js (New)

```
sap.ui.define([
], function () {
    "use strict";
    alert("UI5 is ready");
});
```

Now, we create a new `index.js` script that will contain the application logic for this tutorial step. We do this to avoid having executable code directly in the HTML file for security reasons. This script will be called by the `index.html`. We defined it there as a module in a declarative way.

Standard Variant for Bootstrapping [page 694]
Compatibility Version Information [page 718]
Variant for Bootstrapping from Content Delivery Network [page 696]
https://jquery.org/
Content Security Policy [page 1481]

Step 3: Controls

Now it is time to build our first little UI by replacing the “Hello World” text in the HTML body by the SAPUI5 control `sap.m.Text`. In the beginning, we will use the JavaScript control interface to set up the UI, the control instance is then placed into the HTML body.

Preview

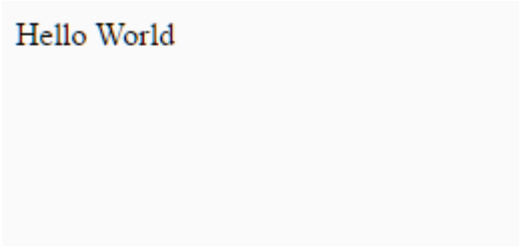

Figure 7: The "Hello World" text is now displayed by a SAPUI5 control

Coding

You can view and download all files at Walkthrough - Step 3.

webapp/index.html

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <title>SAPUI5 Walkthrough</title>
    <script
        id="sap-ui-bootstrap"
        src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-libs="sap.m"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true"
        data-sap-ui-onInit="module:sap/ui/demo/walkthrough/index"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.walkthrough": "./"
        }'>
    </script>
</head>
<body class="sapUiBody" id="content">
</body>
</html>
```

The class `sapUiBody` adds additional theme-dependent styles for displaying SAPUI5 apps.

webapp/index.js

```
sap.ui.define([
    "sap/m/Text"
], function (Text) {
    "use strict";
    new Text({
        text: "Hello World"
    }).placeAt("content");
});
```

Instead of using native JavaScript to display a dialog we want to use a simple SAPUI5 control. Controls are used to define appearance and behavior of parts of the screen.

In the example above, the callback of the `init` event is where we now instantiate a SAPUI5 text control. The name of the control is prefixed by the namespace of its control library `sap/m/` and the options are passed to the constructor with a JavaScript object. For our control we set the `text` property to the value “Hello World”.

We chain the constructor call of the control to the standard method `placeAt` that is used to place SAPUI5 controls inside a node of the document object model (DOM) or any other SAPUI5 control instance. We pass the ID of a DOM node as an argument. As the target node we use the body tag of the HTML document and give it the ID `content`.

All controls of SAPUI5 have a fixed set of properties, aggregations, and associations for configuration. You can find their descriptions in the Demo Kit. In addition, each controls comes with a set of public functions that you can look up in the API reference.

Don’t forget to remove the “Hello World” `p`.

> **i Note**
>
> Only instances of `sap.ui.core.Control` or their subclasses can be rendered stand-alone and have a `placeAt` function. Each control extends `sap.ui.core.Element` that can only be rendered inside controls. Check the API reference to learn more about the inheritance hierarchy of controls. The API documentation of each control refers to the directly known subclasses.

Related Information

Working with Controls [page 1041]

API Reference: `sap.ui.core.Element`
API Reference: `sap.ui.base.ManagedObject`

Step 4: XML Views

Putting all our UI into the `index.html` file will very soon result in a messy setup and there is quite a bit of work ahead of us. So let's do a first modularization by putting the `sap.m.Text` control into a dedicated `view`.

SAPUI5 supports multiple view types (XML, HTML, JavaScript). We choose XML as this produces the most readable code and will force us to separate the view declaration from the controller logic. Yet the look of our UI will not change.

Preview

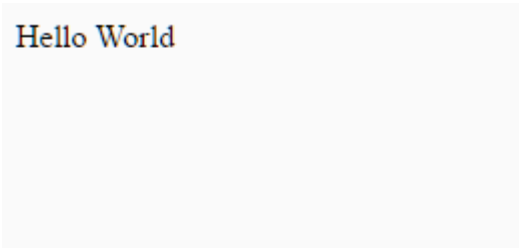

Figure 8: The "Hello World" text is now displayed by a SAPUI5 control (No visual changes to last step)

Coding

You can view and download all files at Walkthrough - Step 4.

webapp/view/App.view.xml (New)

```
<mvc:View
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
</mvc:View>
```

We create a new `view` folder in our app and a new file for our XML view inside the `app` folder. The root node of the XML structure is the `view`. Here, we reference the default namespace `sap.m` where the majority of our UI assets are located. We define an additional `sap.ui.core.mvc` namespace with alias `mvc`, where the SAPUI5 views and all other Model-View-Controller (MVC) assets are located.

> **i** Note
>
> The namespace identifies all resources of the project and has to be unique. If you develop your own application code or controls, you cannot use the namespace prefix `sap`, because this namespace is reserved for SAP resources. Instead, simply define your own unique namespace (for example, `myCompany.myApp`).

webapp/view/App.view.xml

```
<mvc:View
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <Text text="Hello World"/>
</mvc:View>
```

Inside the `view` tag, we add the declarative definition of our `text` control with the same properties as in the previous step. The XML tags are mapped to controls and the attributes are mapped to the properties of the control.

webapp/index.js

```
sap.ui.define([
    "sap/ui/core/mvc/XMLView"
], function (XMLView) {
    "use strict";
    XMLView.create({
        viewName: "sap.ui.demo.walkthrough.view.App"
    }).then(function (oView) {
        oView.placeAt("content");
    });
});
```

We replace the instantiation of the `sap.m.Text` control by our new `App` XML view. The view is created by a factory function of SAPUI5 which makes sure that the view is correctly configured and can be extended by customers. The name is prefixed with the namespace `sap.ui.demo.walkthrough.view` in order to uniquely identify this resource.

> **i Note**
>
> From this step onwards, it is necessary to run the app on a Web server. We structure the app with multiple files that are loaded from the local file system. Without a Web server, this is prevented by the browser due to security reasons. If the error message "sap is not defined" appears in the developer tools of the browser, you need to check the `resource` path in the bootstrap.
>
> You can find more information about how to install a Web server for your particular environment at Development Environment [page 41].

Conventions

- View names are capitalized
- All views are stored in the `view` folder
- Names of XML views always end with `*.view.xml`
- The default XML namespace is `sap.m`
- Other XML namespaces use the last part of the SAP namespace as alias (for example, `mvc` for `sap.ui.core.mvc`)

Related Information

Model View Controller (MVC) [page 784]
Views [page 787]
XML View [page 787]

Step 5: Controllers

In this step, we replace the text with a button and show the “Hello World” message when the button is pressed. The handling of the button's `press` event is implemented in the controller of the view.

Preview

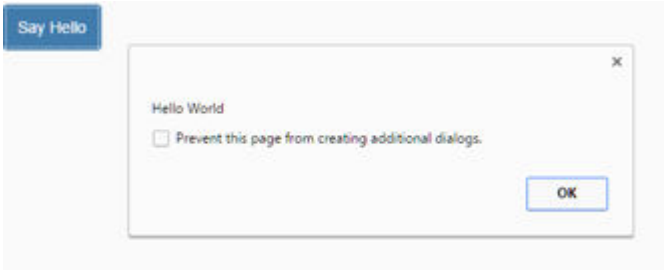

Figure 9: A *Say Hello* button is added

Coding

You can view and download all files at Walkthrough - Step 5.

webapp/view/App.view.xml

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.App"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <Button
      text="Say Hello"
      press=".onShowHello"/>
</mvc:View>
```

We add a reference to the controller, and replace the text control with a button with text “Say Hello”. The button triggers the `.onShowHello` event handler function when being pressed. We also have to specify the name of the controller that is connected to the view and holds the `.onShowHello` function by setting the `controllerName` attribute of the view.

A view does not necessarily need an explicitly assigned controller. You do not have to create a controller if the view is just displaying information and no additional functionality is required. If a controller is specified, it is instantiated after the view is loaded.

webapp/controller/App.controller.js (New)

```
sap.ui.define([
   "sap/ui/core/mvc/Controller"
], function (Controller) {
   "use strict";
   return Controller.extend("", {
   });
});
```

We create the folder `webapp/controller` and a new file `App.controller.js` inside. For now, we ignore the code that manages the required modules. We will explain this part in the next step.

> **i** Note
>
> The `"use strict";` literal expression was introduced by ECMAScript 5. It tells the browser to execute the code in a so called “strict mode”. The strict mode helps to detect potential coding issues at an early state at development time, that means, for example, it makes sure that variables are declared before they are used. Thus, it helps to prevent common JavaScript pitfalls and it's therefore a good practice to use strict mode.

webapp/controller/App.controller.js

```
sap.ui.define([
   "sap/ui/core/mvc/Controller"
], function (Controller) {
   "use strict";
   return Controller.extend("sap.ui.demo.walkthrough.controller.App", {
      onShowHello : function () {
         // show a native JavaScript alert
         alert("Hello World");
      }
   });
});
```

We define the app controller in its own file by extending the `Controller` object of the SAPUI5 core. In the beginning it holds only a single function called `onShowHello` that handles the button's `press` event by showing an alert.

Conventions

- Controller names are capitalized
- Controllers carry the same name as the related view (if there is a 1:1 relationship)
- Event handlers are prefixed with `on`
- Controller names always end with `*.controller.js`

Related Information

Model View Controller (MVC) [page 784]
Controller [page 807]
API Reference: `sap.ui.define`

Step 6: Modules

In SAPUI5, resources are often referred to as modules. In this step, we replace the alert from the last exercise with a proper Message Toast from the `sap.m` library. The required modules are enabled to be loaded asynchronously.

Preview

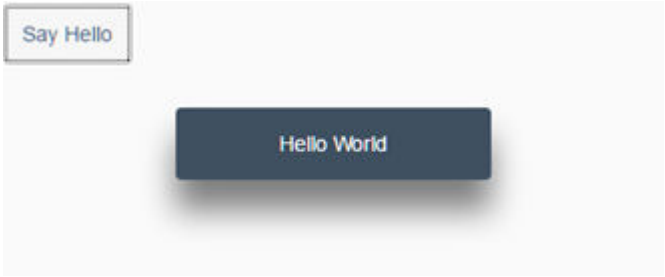

Figure 10: A message toast displays the "Hello World" message

Coding

You can view and download all files at Walkthrough - Step 6.

webapp/controller/App.controller.js

```
sap.ui.define([
   "sap/ui/core/mvc/Controller",
   "sap/m/MessageToast"
], function (Controller, MessageToast) {
   "use strict";
   return Controller.extend("sap.ui.demo.walkthrough.controller.App", {
      onShowHello : function () {
         MessageToast.show("Hello World");
      }
   });
});
```

We extend the array of required modules with the fully qualified path to `sap.m.MessageToast`. Once both modules, `Controller` and `MessageToast`, are loaded, the callback function is called and we can make use of both objects by accessing the parameters passed on to the function.

This Asynchronous Module Definition (AMD) syntax allows to clearly separate the module loading from the code execution and greatly improves the performance of the application. The browser can decide when and how the resources are loaded prior to code execution.

Conventions

- Use `sap.ui.define` for controllers and all other JavaScript modules to define a global namespace. With the namespace, the object can be addressed throughout the application.
- Use `sap.ui.require` for asynchronously loading dependencies but without declaring a namespace, for example code that just needs to be executed, but does not need to be called from other code.
- Use the name of the artifact to load for naming the function parameters (without namespace).

Related Information

API Reference: `sap.ui.define`
API Reference: `sap.ui.require`

Step 7: JSON Model

Now that we have set up the view and controller, it's about time to think about the M in MVC.

We will add an input field to our app, bind its value to the model, and bind the same value to the description of the input field. The description will be directly updated as the user types.

Preview

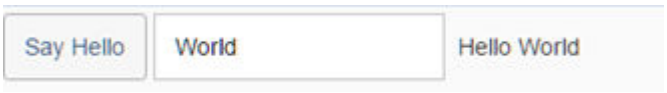

Figure 11: An input field and a description displaying the value of the input field

Coding

You can view and download all files at Walkthrough - Step 7.

webapp/controller/App.controller.js

```
sap.ui.define([
   "sap/ui/core/mvc/Controller",
   "sap/m/MessageToast",
   "sap/ui/model/json/JSONModel"
], function (Controller, MessageToast, JSONModel) {
   "use strict";
   return Controller.extend("sap.ui.demo.walkthrough.controller.App", {
      onInit : function () {
         // set data model on view
         var oData = {
            recipient : {
               name : "World"
            }
         };
         var oModel = new JSONModel(oData);
         this.getView().setModel(oModel);
      },
      onShowHello : function () {
         MessageToast.show("Hello World");
      }
   });
});
```

We add an init function to the controller. `onInit` is one of SAPUI5's lifecycle methods that is invoked by the framework when the controller is created, similar to a constructor function of a control.

Inside the function we instantiate a JSON model. The data for the model only contains a single property for the "recipient", and inside this it also contains one additional property for the name.

To be able to use this model from within the XML view, we call the `setModel` function on the view and pass on our newly created model. The model is now set on the view.

The message toast is just showing the static "Hello World" message. We will show how to load a translated text here in the next step.

webapp/view/App.view.xml

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.App"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <Button
      text="Say Hello"
      press=".onShowHello"/>
   <Input
      value="{/recipient/name}"
      description="Hello {/recipient/name}"
      valueLiveUpdate="true"
      width="60%"/>
</mvc:View>
```

We add an `sap.m.Input` control to the view. With this, the user can enter a recipient for the greetings. We bind its value to a SAPUI5 model by using the declarative binding syntax for XML views:

- The curly brackets `{...}` indicate that data is taken from the value of the `recipient`'s object name property. This is called "data binding".

- `/recipient/name` declares the path in the model.

webapp/index.html

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <title>SAPUI5 Walkthrough</title>
    <script
        id="sap-ui-bootstrap"
        src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-libs="sap.m"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.walkthrough": "./"
        }'
        data-sap-ui-oninit="module:sap/ui/demo/walkthrough/index">
    </script>
    <script src="index.js"></script>
</head>
<body class="sapUiBody" id="content">
</body>
</html>
```

The binding of the value attribute is a simple binding example that contains only a binding pattern. We can also combine texts and binding pattern to a more complex binding result as seen in the description attribute. To be able to use the so-called complex binding syntax we have to enable it globally by setting the bootstrap parameter `data-sap-ui-compatVersion` to `edge`. If this setting is omitted, then only standard binding syntax is allowed, meaning "Hello `{/recipient/name}`" would not work anymore while "`{/recipient/name}`" would work just fine.

> **i Note**
>
> You can either use `data-sap-ui-compatVersion="edge"` or `data-sap-ui-bindingSyntax="complex"` in the script. By setting the "edge" compatibility mode, the complex binding syntax is automatically enabled. The `edge` mode automatically enables compatibility features that otherwise would have to be enabled manually. For more information, see Compatibility Version Information [page 718].

Conventions

- Use Hungarian notation for variable names.

Data Binding [page 815]
JSON Model [page 991]
API Reference: `sap.ui.define`

Step 8: Translatable Texts

In this step we move the texts of our UI to a separate resource file.

This way, they are all in a central place and can be easily translated into other languages. This process of internationalization – in short `i18n` – is achieved in SAPUI5 by using a special resource model and the standard data binding syntax, but without preceding `/`.

Preview

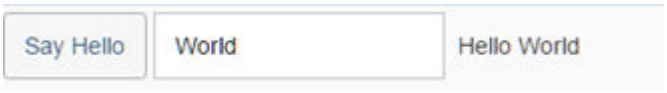

Figure 12: An input field and a description displaying the value of the input field (No visual changes to last step)

Coding

You can view and download all files at Walkthrough - Step 8.

webapp/i18n/i18n.properties (New)

```
showHelloButtonText=Say Hello
helloMsg=Hello {0}
```

We create the folder `webapp/i18n` and the file `i18n.properties` inside. The resolved bundle name is `sap.ui.demo.walkthrough.i18n`, as we will see later. The `properties` file for texts contains name-value pairs for each element. You can add any number of parameters to the texts by adding numbers in curly brackets to them. These numbers correspond to the sequence in which the parameters are accessed (starting with 0).

In this tutorial we will only have one properties file. However, in real-world projects, you would have a separate file for each supported language with a suffix for the locale, for example `i18n_de.properties` for German, `i18n_en.properties` for English, and so on. When a user runs the app, SAPUI5 will load the language file that fits best to the user's environment.

controller/App.controller.js

```
sap.ui.define([
   "sap/ui/core/mvc/Controller",
   "sap/m/MessageToast",
   "sap/ui/model/json/JSONModel",
   "sap/ui/model/resource/ResourceModel"
], function (Controller, MessageToast, JSONModel, ResourceModel) {
   "use strict";
   return Controller.extend("sap.ui.demo.walkthrough.controller.App", {
     onInit : function () {
         // set data model on view
         var oData = {
            recipient : {
               name : "World"
            }
         };
         var oModel = new JSONModel(oData);
         this.getView().setModel(oModel);
         // set i18n model on view
         var i18nModel = new ResourceModel({
            bundleName: "sap.ui.demo.walkthrough.i18n.i18n"
         });
         this.getView().setModel(i18nModel, "i18n");
      },
      onShowHello : function () {
         // read msg from i18n model
         var oBundle = this.getView().getModel("i18n").getResourceBundle();
         var sRecipient = this.getView().getModel().getProperty("/recipient/
name");
         var sMsg = oBundle.getText("helloMsg", [sRecipient]);
         // show message
         MessageToast.show(sMsg);
      }
   });
});
```

In the `onInit` function we instantiate the `ResourceModel` that points to the new message bundle file where our texts are now located (`i18n.properties file`). The bundle name `sap.ui.demo.walkthrough.i18n.i18n` consists of the application namespace `sap.ui.demo.walkthrough` (the application root as defined in the `index.html`), the folder name `i18n` and finally the file name `i18n` without extension. The SAPUI5 runtime calculates the correct path to the resource; in this case the path to our `i18n.properties` file. Next, the model instance is set on the view as a named model with the key `i18n`. You use named models when you need to have several models available in parallel.

In the `onShowHello` event handler function we access the `i18n` model to get the text from the message bundle file and replace the placeholder `{0}` with the recipient from our data model. The `getProperty` method can be called in any model and takes the data path as an argument. In addition, the resource bundle has a specific `getText` method that takes an array of strings as second argument.

The resource bundle can be accessed with the `getResourceBundle` method of a `ResourceModel`. Rather than concatenating translatable texts manually, we can use the second parameter of `getText` to replace parts of the text with non-static data. During runtime, SAPUI5 tries to load the correct `i18n_*.properties` file based on your browser settings and your locale. In our case we have only created one `i18n.properties` file to make it simple. However, you can see in the network traffic of your browser's developer tools that SAPUI5 tries to load one or more `i18n_*.properties` files before falling back to the default `i18n.properties` file.

webapp/view/App.view.xml

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.App"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <Button
      text="{i18n>showHelloButtonText}"
      press=".onShowHello"/>
   <Input
      value="{/recipient/name}"
      description="Hello {/recipient/name}"
      valueLiveUpdate="true"
      width="60%"/>
</mvc:View>
```

In the XML view, we use data binding to connect the button text to the `showHelloButtonText` property in the `i18n` model. A resource bundle is a flat structure, therefore the preceding slash (`/`) can be omitted for the path.

> **i Note**
>
> The description text is not completely localized in this example for illustration purposes. To be on the safe side, we would have to use a similar mechanism as in the controller to use a string from the resource bundle and replace parts of it. This can be done with the `jQuery.sap.formatMessage` formatter.
>
> Furthermore, `i18n` files only impact client-side application texts. Texts that are loaded from back-end systems can appear in all languages that are supported by the back-end system.

Conventions

- The resource model for internationalization is called the `i18n` model.
- The default filename is `i18n.properties`.
- Resource bundle keys are written in (lower) camelCase.
- Resource bundle values can contain parameters like `{0}`, `{1}`, `{2}`, ...
- Never concatenate strings that are translated, always use placeholders.
- Use Unicode escape sequences for special characters.

Related Information

Resource Model [page 995]

API Reference: `jQuery.sap.util.ResourceBundle`

API Reference: `sap.ui.model.resource.ResourceModel`

Samples: `sap.ui.model.resource.ResourceModel`

Step 9: Component Configuration

After we have introduced all three parts of the Model-View-Controller (MVC) concept, we now come to another important structural aspect of SAPUI5.

In this step, we will encapsulate all UI assets in a component that is independent from our `index.html` file. Components are independent and reusable parts used in SAPUI5 applications. Whenever we access resources, we will now do this relatively to the component (instead of relatively to the `index.html`). This architectural change allows our app to be used in more flexible environments than our static `index.html` page, such as in a surrounding container like the SAP Fiori launchpad.

Preview

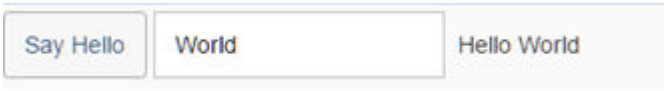

Figure 13: An input field and a description displaying the value of the input field (No visual changes to last step)

Coding

You can view and download all files at Walkthrough - Step 9.

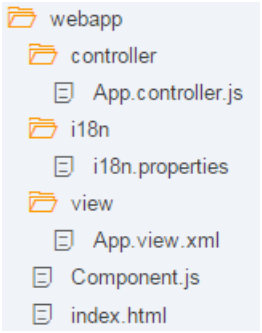

Figure 14: Folder Structure for this Step

After this step your project structure will look like the figure above. We will create the `Component.js` file now and modify the related files in the app.

webapp/Component.js (New)

```
sap.ui.define([
   "sap/ui/core/UIComponent"
], function (UIComponent) {
   "use strict";
   return UIComponent.extend("", {

      init : function () {
         // call the init function of the parent
```

```
            UIComponent.prototype.init.apply(this, arguments);
        }
    });
});
```

We create an initial `Component.js` file in the `webapp` folder that will hold our application setup. The init function of the component is automatically invoked by SAPUI5 when the component is instantiated. Our component inherits from the base class `sap.ui.core.UIComponent` and it is obligatory to make the super call to the `init` function of the base class in the overridden `init` method.

webapp/Component.js

```
sap.ui.define([
   "sap/ui/core/UIComponent",
   "sap/ui/model/json/JSONModel",
   "sap/ui/model/resource/ResourceModel"
], function (UIComponent, JSONModel, ResourceModel) {
   "use strict";
   return UIComponent.extend("sap.ui.demo.walkthrough.Component", {
      metadata : {
         rootView: {
            "viewName": "sap.ui.demo.walkthrough.view.App",
            "type": "XML",
            "async": true,
            "id": "app"
         }
      },
      init : function () {
         // call the init function of the parent
         UIComponent.prototype.init.apply(this, arguments);
         // set data model
         var oData = {
            recipient : {
               name : "World"
            }
         };
         var oModel = new JSONModel(oData);
         this.setModel(oModel);

         // set i18n model
         var i18nModel = new ResourceModel({
            bundleName : "sap.ui.demo.walkthrough.i18n.i18n"
         });
         this.setModel(i18nModel, "i18n");
      }
   });
});
```

The `Component.js` file consists of two parts now: The new `metadata` section that simply defines a reference to the root view and the previously introduced `init` function that is called when the component is initialized. Instead of displaying the root view directly in the `index.html` file as we did previously, the component will now manage the display of the app view.

In the `init` function we instantiate our data model and the `i18n` model like we did before in the app controller. Be aware that the models are directly set on the component and not on the root view of the component. However, as nested controls automatically inherit the models from their parent controls, the models will be available on the view as well.

webapp/controller/App.controller.js

```
sap.ui.define([
   "sap/ui/core/mvc/Controller",
   "sap/m/MessageToast"
], function (Controller, MessageToast) {
   "use strict";
   return Controller.extend("sap.ui.demo.walkthrough.controller.App", {
      onShowHello : function () {
         // read msg from i18n model
         var oBundle = this.getView().getModel("i18n").getResourceBundle();
         var sRecipient = this.getView().getModel().getProperty("/recipient/
name");
         var sMsg = oBundle.getText("helloMsg", [sRecipient]);
         // show message
         MessageToast.show(sMsg);
      }
   });
});
```

Delete the `onInit` function and the required modules; this is now done in the component. You now have the code shown above.

webapp\index.js

```
sap.ui.define([
    "sap/ui/core/ComponentContainer"
], function (ComponentContainer) {
    "use strict";
    new ComponentContainer({
        name: "sap.ui.demo.walkthrough",
        settings : {
            id : "walkthrough"
        },
        async: true
    }).placeAt("content");
});
```

We now create a component container instead of the view in our `index.js` that instantiates the view for us according to the component configuration.

Conventions

- The component is named `Component.js`.
- Together with all UI assets of the app, the component is located in the `webapp` folder.
- The `index.html` file is located in the `webapp` folder if it is used productively.

Related Information

Components [page 720]

Samples: `sap.ui.core.mvc.ViewType`
Declarative API for Initial Components [page 731]
Make Your App CSP Compliant [page 687]

Step 10: Descriptor for Applications

All application-specific configuration settings will now further be put in a separate descriptor file called `manifest.json`. This clearly separates the application coding from the configuration settings and makes our app even more flexible. For example, all SAP Fiori applications are realized as components and come with a descriptor file in order to be hosted in the SAP Fiori launchpad.

The SAP Fiori launchpad acts as an application container and instantiates the app without having a local HTML file for the bootstrap. Instead, the descriptor file will be parsed and the component is loaded into the current HTML page. This allows several apps to be displayed in the same context. Each app can define local settings, such as language properties, supported devices, and more. And we can also use the descriptor file to load additional resources and instantiate models like our `i18n` resource bundle.

Preview

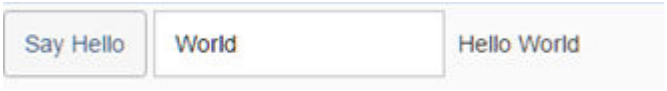

Figure 15: An input field and a description displaying the value of the input field (No visual changes to last step)

Coding

You can view and download all files at Walkthrough - Step 10.

> ⚠ Caution
>
> Automatic model instantiation is only available as of SAPUI5 version 1.30. If you are using an older version, you can manually instantiate the resource bundle and other models of the app in the `init` method of the `Component.js` file as we did in Step 9: Component Configuration [page 88].

webapp/manifest.json (New)

```
{
  "_version": "1.12.0",
```

```
  "sap.app": {
    "id": "sap.ui.demo.walkthrough",
    "type": "application",
    "i18n": "i18n/i18n.properties",
    "title": "{{appTitle}}",
    "description": "{{appDescription}}",
    "applicationVersion": {
      "version": "1.0.0"
    }
  },
  "sap.ui": {
    "technology": "UI5",
    "deviceTypes": {
        "desktop": true,

}
```

> **i Note**
>
> In this tutorial, we only introduce the most important settings and parameters of the descriptor file. In SAP Web IDE, you may get validation errors because some settings are missing - you can ignore those in this context.

The content of the `manifest.json` file is a configuration object in JSON format that contains all global application settings and parameters. The manifest file is called the descriptor for applications, components, and libraries and is also referred to as “descriptor” or “app descriptor” when used for applications. It is stored in the `webapp` folder and read by SAPUI5 to instantiate the component. There are three important sections defined by namespaces in the `manifest.json` file:

- `sap.app`
  The `sap.app` namespace contains the following application-specific attributes:
  - `id` (mandatory): The namespace of our application component
    The ID must not exceed 70 characters. It must be unique and must correspond to the component ID/ namespace.
  - `type`: Defines what we want to configure, here: an application
  - `i18n`: Defines the path to the resource bundle file

- `title`: Title of the application in handlebars syntax referenced from the app's resource bundle
- `description`: Short description text what the application does in handlebars syntax referenced from the app's resource bundle
- `applicationVersion`: The version of the application to be able to easily update the application later on

- `sap.ui`
  The `sap.ui namespace` contributes the following UI-specific attributes:
  - `technology`: This value specifies the UI technology; in our case we use SAPUI5
  - `deviceTypes`: Tells what devices are supported by the app: desktop, tablet, phone (all true by default)
- **sap.ui5**
  The `sap.ui5` namespace adds SAPUI5-specific configuration parameters that are automatically processed by SAPUI5. The most important parameters are:
  - `rootView`: If you specify this parameter, the component will automatically instantiate the view and use it as the root for this component
  - `dependencies`: Here we declare the UI libraries used in the application
  - `models`: In this section of the descriptor we can define models that will be automatically instantiated by SAPUI5 when the app starts. Here we can now define the local resource bundle. We define the name of the model "i18n" as key and specify the bundle file by namespace. As in the previous steps, the file with our translated texts is stored in the `i18n` folder and named `i18n.properties`. We simply prefix the path to the file with the namespace of our app. The manual instantiation in the app component's init method will be removed later in this step.

  For compatibility reasons the root object and each of the sections state the descriptor version number `1.1.0` under the internal property `_version`. Features might be added or changed in future versions of the descriptor and the version number helps to identify the application settings by tools that read the descriptor.

> **i Note**
>
> Properties of the resource bundle are enclosed in two curly brackets in the descriptor. This is not a SAPUI5 data binding syntax, but a variable reference to the resource bundle in the descriptor in handlebars syntax. The referred texts are not visible in the app built in this tutorial but can be read by an application container like the SAP Fiori launchpad.

webapp\index.html

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <title>SAPUI5 Walkthrough</title>
    <script
        id="sap-ui-bootstrap"
        src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.walkthrough": "./"
        }'
        data-sap-ui-oninit="module:sap/ui/core/ComponentSupport"
        data-sap-ui-compatVersion="edge"
```

```
        data-sap-ui-async="true">
    </script>
</head>
<body class="sapUiBody" id="content">
    <div data-sap-ui-component data-name="sap.ui.demo.walkthrough" data-
id="container" data-settings='{"id" : "walkthrough"}'></div>
</body>
</html>
```

Now we declare our component in the body of our `index.html`. In the bootstrapping script of our `index.html`, we enable the `ComponentSupport` module and remove the `sap.m` library. Then, we declare our component in the body via a `div` tag. This will instantiate the component when the `onInit` event is executed.

We will no longer need our `index.js` from now on, because the descriptor takes care of everything.

webapp/i18n/i18n.properties

```
# App Descriptor
appTitle=Hello World
appDescription=A simple walkthrough app that explains the most important
concepts of SAPUI5

# Hello Panel
showHelloButtonText=Say Hello
helloMsg=Hello {0}
```

In the resource bundle we simply add the texts for the app and add comments to separate the bundle texts semantically.

webapp/Component.js

```
sap.ui.define([
   "sap/ui/core/UIComponent",
   "sap/ui/model/json/JSONModel"
], function (UIComponent, JSONModel) {
   "use strict";
   return UIComponent.extend("sap.ui.demo.walkthrough.Component", {
      metadata : {
            manifest: "json"
      },
      init : function () {
         // call the init function of the parent
         UIComponent.prototype.init.apply(this, arguments);
         // set data model
         var oData = {
            recipient : {
               name : "World"
            }
         };
         var oModel = new JSONModel(oData);
         this.setModel(oModel);
      }
   });
});
```

In the component's `metadata` section, we now replace the `rootView` property with the property key `manifest` and the value `json`. This defines a reference to the descriptor that will be loaded and parsed automatically when the component is instantiated. We can now completely remove the lines of code containing the model instantiation for our resource bundle. It is done automatically by SAPUI5 with the help of the configuration entries in the descriptor. We can also remove the dependency to `sap/ui/model/resource/ResourceModel` and the corresponding formal parameter `ResourceModel` because we will not use this inside our anonymous callback function.

> → Tip
>
> In previous versions of SAPUI5, additional configuration settings for the app, like the service configuration, the root view, and the routing configuration, had to be added to the metadata section of the `Component.js` file. As of SAPUI5 version 1.30, we recommend that you define these settings in the `manifest.json` descriptor file. Apps and examples that were created based on an older SAPUI5 version still use the `Component.js` file for this purpose - so it is still supported, but not recommended.

Conventions

- The descriptor file is named `manifest.json` and located in the `webapp` folder.
- Use translatable strings for the title and the description of the app.

Descriptor for Applications, Components, and Libraries [page 734]

Step 11: Pages and Panels

After all the work on the app structure it's time to improve the look of our app. We will use two controls from the `sap.m` library to add a bit more "bling" to our UI. You will also learn about control aggregations in this step.

Preview

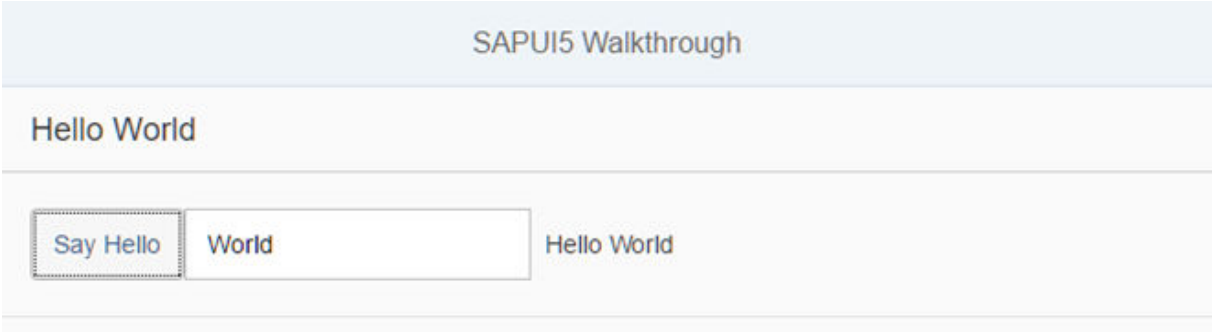

Figure 16: A panel is now displaying the controls from the previous steps

Coding

You can view and download all files at Walkthrough - Step 11.

webapp/view/App.view.xml

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.App"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc"
  displayBlock="true">
   <App>
      <pages>
         <Page title="{i18n>homePageTitle}">
            <content>
               <Panel
                  headerText="{i18n>helloPanelTitle}">
                  <content>
                     <Button
                        text="{i18n>showHelloButtonText}"
                        press=".onShowHello"/>
                     <Input
                        value="{/recipient/name}"
                        description="Hello {/recipient/name}"
                        valueLiveUpdate="true"
                        width="60%"/>
                  </content>
               </Panel>
            </content>
         </Page>
      </pages>
   </App>
```

```
</mvc:View>
```

We put both the input field and the button inside a containing control called `sap.m.Page`. The page provides an aggregation to `0..N` other controls called `content`. It also displays the title attribute in a header section on top of the content. The page itself is placed into the `pages` aggregation of another control called `sap.m.App` which does the following important things for us:

- It writes a bunch of properties into the header of the `index.html` that are necessary for proper display on mobile devices.
- It offers functionality to navigate between pages with animations. We will use this soon.

In order to make the fullscreen height of the view work properly, we add the `displayBlock` attribute with the value `true` to the view. The actual content is wrapped inside a `Panel` control, in order to group related content.

webapp/i18n/i18n.properties

```
# App Descriptor
appTitle=Hello World
appDescription=A simple walkthrough app that explains the most important
concepts of SAPUI5
# Hello Panel
showHelloButtonText=Say Hello
helloMsg=Hello {0}
homePageTitle=Walkthrough
helloPanelTitle=Hello World
```

We add new key/value pairs to our text bundle for the start page title and the panel title.

Samples: `sap.m.NavContainer`
API Reference: `sap.m.Page`
Samples: `sap.m.Page`

Step 12: Shell Control as Container

Now we use a shell control as container for our app and use it as our new root element. The shell takes care of visual adaptation of the application to the device's screen size by introducing a so-called letterbox on desktop screens.

Preview

Figure 17: The app is now run in a shell that limits the app width

Coding

You can view and download all files at Walkthrough - Step 12.

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    displayBlock="true">
    <Shell>
        <App>
            <pages>
                <Page title="{i18n>homePageTitle}">
                    <content>
                        <Panel
                            headerText="{i18n>helloPanelTitle}">
                            <content>
                                <Button
                                    text="{i18n>showHelloButtonText}"
                                    press=".onShowHello"/>
                                <Input
                                    value="{/recipient/name}"
                                    description="Hello {/recipient/name}"
                                    valueLiveUpdate="true"
                                    width="60%"/>
                            </content>
                        </Panel>
                    </content>
                </Page>
            </pages>
```

```
        </App>
    </Shell>
</mvc:View>
```

The shell control is now the outermost control of our app and automatically displays a so-called letterbox, if the screen size is larger than a certain width.

> **i Note**
>
> We do not add the `Shell` control to the declarative UI definition in the XML view, because apps that run in an external shell, like the SAP Fiori launchpad, there will already be a shell around the component UI.

There are further options to customize the shell, like setting a custom background image or color and setting a custom logo. Check the related API reference for more details.

Related Information

API Reference: `sap.m.Shell`

Step 13: Margins and Paddings

Our app content is still glued to the corners of the letterbox. To fine-tune our layout, we can add margins and paddings to the controls that we added in the previous step.

Instead of manually adding CSS to the controls, we will use the standard classes provided by SAPUI5. These classes take care of consistent sizing steps, left-to-right support, and responsiveness.

Preview

Figure 18: The layout of the panel and its content now has margins and padding

Coding

You can view and download all files at Walkthrough - Step 13.

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    displayBlock="true">
    <Shell>
        <App>
            <pages>
                <Page title="{i18n>homePageTitle}">
                    <content>
                        <Panel
                            headerText="{i18n>helloPanelTitle}"
                            class="sapUiResponsiveMargin"
                            width="auto">
                            <content>
                                <Button
                                    text="{i18n>showHelloButtonText}"
                                    press=".onShowHello"
                                    class="sapUiSmallMarginEnd"/>
                                <Input
                                    value="{/recipient/name}"
                                    valueLiveUpdate="true"
                                    width="60%"/>
                                <Text
                                    text="Hello {/recipient/name}"
                                    class="sapUiSmallMargin"/>
                            </content>
                        </Panel>
                    </content>
                </Page>
            </pages>
        </App>
    </Shell>
</mvc:View>
```

To layout the panel, we add the CSS class `sapUiResponsiveMargin` that will add some space around the panel. We have to set the width of the panel to `auto` since the margin would otherwise be added to the default width of 100% and exceed the page size.

If you decrease the screen size, then you can actually see that the margin also decreases. As the name suggests, the margin is responsive and adapts to the screen size of the device. Tablets will get a smaller margin and phones in portrait mode will not get a margin to save space on these small screens.

Margins can be added to all kinds of controls and are available in many different options. We can even add space between the button and the input field by adding class `sapUiSmallMarginEnd` to the button.

To format the output text individually, we remove the description from the input field and add a new `Text` control with the same value. Here we also use a small margin to align it with the other content. Similarly, we could add the standard padding classes to layout the inner parts of container controls such as our panel, but as it already brings a padding by default, this is not needed here.

Conventions

- Use the standard SAPUI5 CSS classes for the layout if possible.

Related Information

Using Predefined CSS Margin Classes [page 1046]
Using Container Content Padding CSS Classes [page 1051]

Step 14: Custom CSS and Theme Colors

Sometimes we need to define some more fine-granular layouts and this is when we can use the flexibility of CSS by adding custom style classes to controls and style them as we like.

Preview

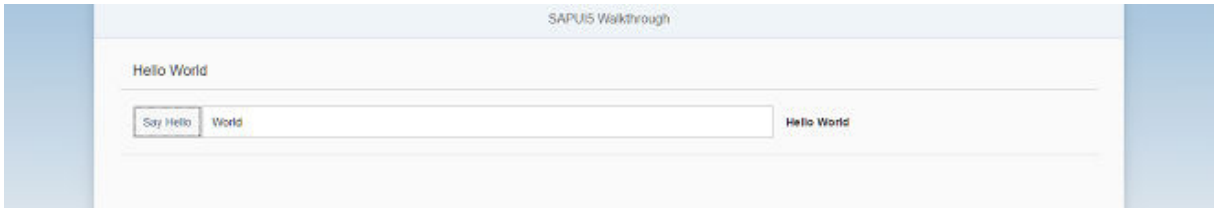

Figure 19: The space between the button and the input field is now smaller and the output text is bold

> ⚠ Caution
>
> As stated in the *Compatibility Rules*, the HTML and CSS generated by SAPUI5 is not part of the public API and may change in patch and minor releases. If you decide to override styles, you have the obligation to test and update your modifications each time SAPUI5 is updated. A prerequisite for this is that you have control over the version of SAPUI5 being used, for example in a standalone scenario. This is not possible when running your app in the SAP Fiori launchpad where SAPUI5 is centrally loaded for all apps. As such, SAP Fiori launchpad apps should not override styles.

Coding

You can view and download all files at Walkthrough - Step 14.

webapp/css/style.css (New)

```
html[dir="ltr"] .myAppDemoWT .myCustomButton.sapMBtn {
   margin-right: 0.125rem
}
```

```
html[dir="rtl"] .myAppDemoWT .myCustomButton.sapMBtn {
   margin-left: 0.125rem
}

.myAppDemoWT .myCustomText {
   display: inline-block;
   font-weight: bold;
}
```

We create a folder `css` which will contain our CSS files. In a new style definition file inside the `css` folder we create our custom classes combined with a custom namespace class. This makes sure that the styles will only be applied on controls that are used within our app.

A button has a default margin of `0` that we want to override: We add a custom margin of `2px` (or `0.125rem` calculated relatively to the default font size of `16px`) to the button with the style class `myCustomButton`. We add the CSS class `sapMBtn` to make our selector more specific: in CSS, the rule with the most specific selector "wins".

For right-to-left (rtl) languages, like Arabic, you set the left margin and reset the right margin as the app display is inverted. If you only use standard SAPUI5 controls, you don't need to care about this, in this case where we use custom CSS, you have to add this information.

In an additional class `myCustomText` we define a bold text and set the display to `inline-block`. This time we just define our custom class without any additional selectors. We do not set a color value here yet, we will do this in the view.

webapp/manifest.json

```
...
  "sap.ui5": {
    ...
    "models": {
      ...
    },
    "resources": {
      "css": [
        {
          "uri": "css/style.css"
        }
      ]
    }
  }
```

In the `resources` section of the `sap.ui5` namespace, additional resources for the app can be loaded. We load the CSS styles by defining a URI relative to the component. SAPUI5 then adds this file to the header of the HTML page as a `<link>` tag, just like in plain Web pages, and the browser loads it automatically.

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.App"
    xmlns="sap.m"
```

```
    xmlns:mvc="sap.ui.core.mvc"
    displayBlock="true">
    <Shell>
        <App class="myAppDemoWT">
            <pages>
                <Page title="{i18n>homePageTitle}">
                    <content>
                        <Panel
                            headerText="{i18n>helloPanelTitle}"
                            class="sapUiResponsiveMargin"
                            width="auto">
                            <content>
                                <Button
                                    text="{i18n>showHelloButtonText}"
                                    press=".onShowHello"
                                    class="myCustomButton"/>
                                <Input
                                    value="{/recipient/name}"
                                    valueLiveUpdate="true"
                                    width="60%"/>
                                <FormattedText
                                    htmlText="Hello {/recipient/name}"
                                    class="sapUiSmallMargin sapThemeHighlight-
asColor myCustomText"/>
                            </content>
                        </Panel>
                    </content>
                </Page>
            </pages>
        </App>
    </Shell>
</mvc:View>
```

The app control is configured with our custom namespace class `myAppDemoWT`. This class has no styling rules set and is used in the definition of the CSS rules to define CSS selectors that are only valid for this app.

We add our custom CSS class to the button to precisely define the space between the button and the input field. Now we have a pixel-perfect design for the panel content.

To highlight the output text, we use a `FormattedText` control which can be styled individually, either by using custom CSS or with HTML code. We add our custom CSS class (`myCustomText`) and add a theme-dependent CSS class to set the highlight color that is defined in the theme.

The actual color now depends on the selected theme which ensures that the color always fits to the theme and is semantically clear. For a complete list of the available CSS class names, see CSS Classes for Theme Parameters [page 1262].

Conventions

- Do not specify colors in custom CSS but use the standard theme-dependent classes instead.

Step 15: Nested Views

Our panel content is getting more and more complex and now it is time to move the panel content to a separate view. With that approach, the application structure is much easier to understand, and the individual parts of the app can be reused.

Preview

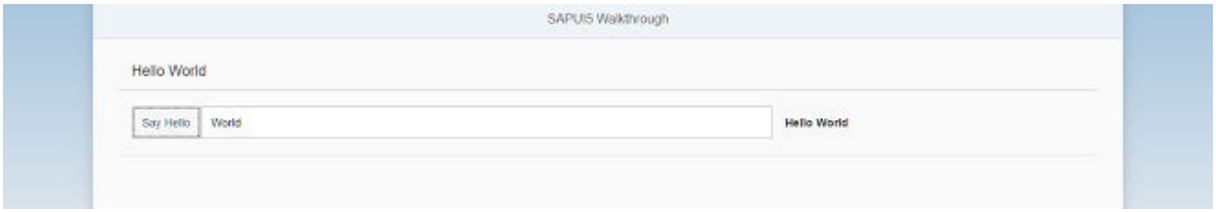

Figure 20: The panel content is now refactored to a separate view (No visual changes to last step)

Coding

You can view and download all files at Walkthrough - Step 15.

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    displayBlock="true">
    <Shell>
        <App class="myAppDemoWT">
            <pages>
                <Page title="{i18n>homePageTitle}">
                    <content>
                        <mvc:XMLView
viewName="sap.ui.demo.walkthrough.view.HelloPanel"/>
                    </content>
                </Page>
            </pages>
        </App>
    </Shell>
</mvc:View>
```

Instead of putting the panel and its content directly into our `App` view, we will move it to a new separate `HelloPanel` view. We refer to this using an `XMLView` tag in the content aggregation of the panel.

webapp/view/HelloPanel.view.xml (New)

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.HelloPanel"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <Panel
      headerText="{i18n>helloPanelTitle}"
      class="sapUiResponsiveMargin"
      width="auto" >
      <content>
         <Button
            text="{i18n>showHelloButtonText}"
            press=".onShowHello"
            class="myAppDemoWT myCustomButton"/>
         <Input
            value="{/recipient/name}"
            valueLiveUpdate="true"
            width="60%"/>
         <FormattedText
            htmlText="Hello {/recipient/name}"
            class="sapUiSmallMargin sapThemeHighlight-asColor myCustomText"/>
      </content>
   </Panel>
</mvc:View>
```

The whole content for the panel is now added to the new file `HelloPanel.view.xml`. We also specify the controller for the view by setting the `controllerName` attribute of the XML view.

webapp/controller/HelloPanel.controller.js (New)

```
sap.ui.define([
   "sap/ui/core/mvc/Controller",
   "sap/m/MessageToast"
], function (Controller, MessageToast) {
   "use strict";
   return Controller.extend("sap.ui.demo.walkthrough.controller.HelloPanel", {
      onShowHello : function () {
         // read msg from i18n model
         var oBundle = this.getView().getModel("i18n").getResourceBundle();
         var sRecipient = this.getView().getModel().getProperty("/recipient/
name");
         var sMsg = oBundle.getText("helloMsg", [sRecipient]);
         // show message
         MessageToast.show(sMsg);
      }
   });
});
```

To have a reusable asset, the method `onShowHello` is also moved from the app controller to the `HelloPanel` controller.

webapp/controller/App.controller.js

```
sap.ui.define([
   "sap/ui/core/mvc/Controller"
], function (Controller) {
   "use strict";
   return Controller.extend("sap.ui.demo.walkthrough.controller.App", {
   });
});
```

We have now moved everything out of the app view and controller. The app controller remains an empty stub for now, we will use it later to add more functionality.

Step 16: Dialogs and Fragments

In this step, we will take a closer look at another element which can be used to assemble views: the fragment.

Fragments are light-weight UI parts (UI subtrees) which can be reused but do not have any controller. This means, whenever you want to define a certain part of your UI to be reusable across multiple views, or when you want to exchange some parts of a view against one another under certain circumstances (different user roles, edit mode vs read-only mode), a fragment is a good candidate, especially where no additional controller logic is required.

A fragment can consist of 1 to n controls. At runtime, fragments placed in a view behave similar to "normal" view content, which means controls inside the fragment will just be included into the view's DOM when rendered. There are of course controls that are not designed to become part of a view, for example, dialogs.

But even for these controls, fragments can be particularly useful, as you will see in a minute.

We will now add a dialog to our app. Dialogs are special, because they open on top of the regular app content and thus do not belong to a specific view. That means the dialog must be instantiated somewhere in the controller code, but since we want to stick with the declarative approach and create reusable artifacts to be as flexible as possible, and because dialogs cannot be specified as views, we will create an XML fragment containing the dialog. A dialog, after all, can be used in more than only one view of your app.

Preview

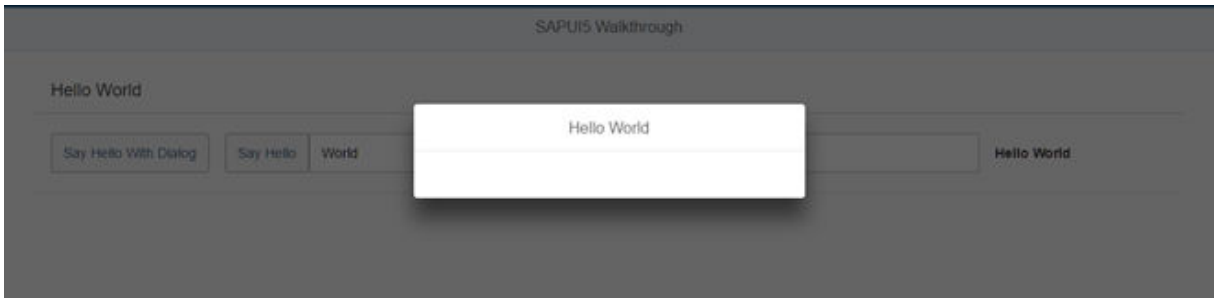

Figure 21: A dialog opens when the new "Say Hello With Dialog" button is clicked

Coding

You can view and download all files at Walkthrough - Step 16.

webapp/view/HelloPanel.view.xml

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.HelloPanel"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <Panel
      headerText="{i18n>helloPanelTitle}"
      class="sapUiResponsiveMargin"
      width="auto" >
      <content>
      <Button
         id="helloDialogButton"
         text="{i18n>openDialogButtonText}"
         press=".onOpenDialog"
         class="sapUiSmallMarginEnd"/>
      <Button
         text="{i18n>showHelloButtonText}"
         press=".onShowHello"
         class="myCustomButton"/>
      <Input
         value="{/recipient/name}"
         valueLiveUpdate="true"
         width="60%"/>
      <FormattedText
         htmlText="Hello {/recipient/name}"
         class="sapUiSmallMargin sapThemeHighlight-asColor myCustomText"/>
      </content>
   </Panel>
</mvc:View>
```

We add a new button to the view to open the dialog. It simply calls an event handler function in the controller of the panel's content view. We will need the new `id="helloDialogButton"` in Step 29: Integration Test with OPA [page 151].

It is a good practice to set a unique ID like `helloWorldButton` to key controls of your app so that can be identified easily. If the attribute `id` is not specified, the OpenUI5 runtime generates unique but changing ID like `__button23` for the control. Inspect the DOM elements of your app in the browser to see the difference.

webapp/view/HelloDialog.fragment.xml (New)

```
<core:FragmentDefinition
   xmlns="sap.m"
   xmlns:core="sap.ui.core" >
   <Dialog
      id="helloDialog"
      title="Hello {/recipient/name}">
   </Dialog>
</core:FragmentDefinition>
```

We add a new XML file to declaratively define our dialog in a fragment. The fragment assets are located in the `core` namespace, so we add an `xml` namespace for it inside the `FragmentDefinition` tag.

The syntax is similar to a view, but since fragments do not have a controller this attribute is missing. Also, the fragment does not have any footprint in the DOM tree of the app, and there is no control instance of the fragment itself (only the contained controls). It is simply a container for a set of reuse controls.

We also add an `id` for our `Dialog` to be able to access the dialog from our `HelloPanel` controller.

webapp/controller/HelloPanel.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageToast",
    "sap/ui/core/Fragment"
], function (Controller, MessageToast, Fragment) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.HelloPanel", {
        onShowHello : function () {
            …
        },
        onOpenDialog : function () {
            var oView = this.getView();

            // create dialog lazily
            if (!this.byId("helloDialog")) {
                // load asynchronous XML fragment
                Fragment.load({
                    id: oView.getId(),
                    name: "sap.ui.demo.walkthrough.view.HelloDialog"
                }).then(function (oDialog) {
                    // connect dialog to the root view of this component
(models, lifecycle)
                    oView.addDependent(oDialog);
                    oDialog.open();
                });
            } else {
                this.byId("helloDialog").open();
            }
        }
    });
});
```

If the dialog in the fragment does not exist yet, the fragment is instantiated by calling the `sap.ui.xmlfragment` method with the following arguments:

- The ID of the `HelloPanel` view
  This parameter is used to prefix the IDs inside our fragment. There, we have defined the ID `helloDialog` for the `Dialog` control, and we can access the dialog via the view by calling `oView.byId("helloDialog")`. This makes sure that even if you instantiate the same fragment in other views in the same way, each dialog will have its unique ID that is concatenated from the view ID and the dialog ID.
  Using unique IDs is important, because duplicate IDs lead to errors in the framework.
- The path of the fragment definition

We add the dialog as "dependent" on the view to be connected to the lifecycle of the view's model. A convenient side-effect is that the dialog will automatically be destroyed when the view is destroyed. Otherwise, we would have to destroy the dialog manually to free its resources.

Conventions

- Always use the `addDependent` method to connect the dialog to the lifecycle management and data binding of the view, even though it is not added to its UI tree.
- Private functions and variables should always start with an underscore.

webapp/i18n/i18n.properties

```
# App Descriptor
appTitle=Hello World
appDescription=A simple walkthrough app that explains the most important
concepts of SAPUI5
# Hello Panel
showHelloButtonText=Say Hello
helloMsg=Hello {0}
homePageTitle=Walkthrough
helloPanelTitle=Hello World
openDialogButtonText=Say Hello With Dialog
```

We add a new text for the open button to the text bundle.

API Reference: `sap.ui.core.Fragment`

Step 17: Fragment Callbacks

Now that we have integrated the dialog, it's time to add some user interaction. The user will definitely want to close the dialog again at some point, so we add a button to close the dialog and assign an event handler.

Preview

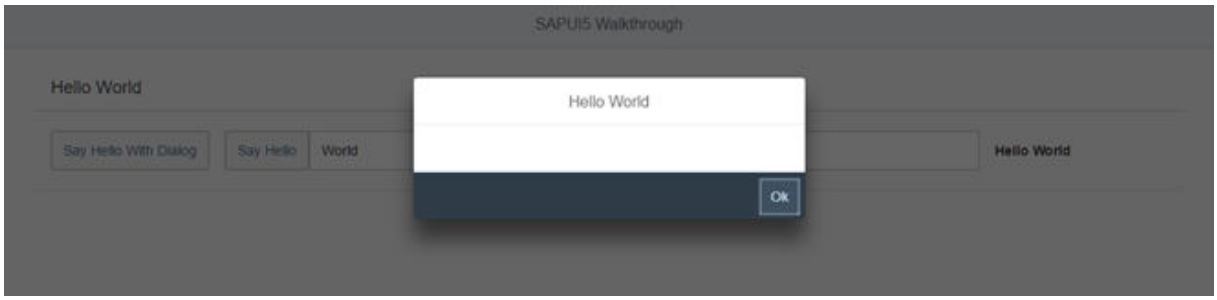

Figure 22: The dialog now has an "OK" button

Coding

You can view and download all files at Walkthrough - Step 17.

webapp/controller/HelloPanel.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageToast",
    "sap/ui/core/Fragment"
], function (Controller, MessageToast, Fragment) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.HelloPanel", {
        onShowHello : function () {
            // read msg from i18n model
            var oBundle = this.getView().getModel("i18n").getResourceBundle();
            var sRecipient = this.getView().getModel().getProperty("/recipient/
name");
            var sMsg = oBundle.getText("helloMsg", [sRecipient]);
            // show message
            MessageToast.show(sMsg);
        },
        onOpenDialog : function () {
            var oView = this.getView();
            // create dialog lazily
            if (!this.byId("helloDialog")) {
                // load asynchronous XML fragment
                Fragment.load({
                    id: oView.getId(),
                    name: "sap.ui.demo.walkthrough.view.HelloDialog",
                    controller: this
                }).then(function (oDialog) {
```

```
                    // connect dialog to the root view of this component
(models, lifecycle)
                    oView.addDependent(oDialog);
                    oDialog.open();
                });
            } else {
                this.byId("helloDialog").open();
            }
        },

        onCloseDialog : function () {
            this.byId("helloDialog").close();
        }
    });
});
```

As previously described, fragments are pure UI reuse artifacts and do not have a controller. The third parameter of the `sap.ui.xmlfragment` function is optional and allows passing in a reference to a (controller) object. For our dialog we reference the `HelloPanel` controller. However, the third parameter does not necessarily have to be a controller but can be any object. Just don't forget the `this` keyword.

The event handler function is put into the same controller file and it closes the dialog by accessing the internal helper function that returns the dialog.

webapp/view/HelloDialog.fragment.xml

```
<core:FragmentDefinition
   xmlns="sap.m"
   xmlns:core="sap.ui.core" >
   <Dialog
      id="helloDialog"
      title ="Hello {/recipient/name}">
      <beginButton>
         <Button
            text="{i18n>dialogCloseButtonText}"
            press=".onCloseDialog"/>
      </beginButton>
   </Dialog>
</core:FragmentDefinition>
```

In the fragment definition, we add a button to the `beginButton` aggregation of the dialog. The press handler is referring to an event handler called `.onCloseDialog`, and since we passed in the reference to the `HelloPanel` controller, the method will be invoked there when the button is pressed. The dialog has an aggregation named `beginButton` as well as `endButton`. Placing buttons in both of these aggregations makes sure that the `beginButton` is placed before the `endButton` on the UI. What `before` means, however, depends on the text direction of the current language. We therefore use the terms `begin` and `end` as a synonym to “left” and “right". In languages with left-to-right direction, the `beginButton` will be rendered left, the `endButton` on the right side of the dialog footer; in right-to-left mode for specific languages the order is switched.

webapp/i18n/i18n.properties

```
# App Descriptor
appTitle=Hello World
appDescription=A simple walkthrough app that explains the most important
concepts of SAPUI5
# Hello Panel
showHelloButtonText=Say Hello
helloMsg=Hello {0}
homePageTitle=Walkthrough
helloPanelTitle=Hello World
openDialogButtonText=Say Hello With Dialog
dialogCloseButtonText=Ok
```

The text bundle is extended by the new text for the dialog's close button.

Related Information

Reusing UI Parts: Fragments [page 1004]
Instantiation of Fragments [page 1006]

Step 18: Icons

Our dialog is still pretty much empty. Since SAPUI5 is shipped with a large icon font that contains more than 500 icons, we will add an icon to greet our users when the dialog is opened.

Preview

Figure 23: An icon is now displayed in the dialog box

Coding

You can view and download all files at Walkthrough - Step 18.

webapp/view/HelloPanel.view.xml

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.HelloPanel"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <Panel
      headerText="{i18n>helloPanelTitle}"
      class="sapUiResponsiveMargin"
      width="auto" >
      <content>
         <Button
            id="helloDialogButton"
            icon="sap-icon://world"
            text="{i18n>openDialogButtonText}"
            press=".onOpenDialog"
            class="sapUiSmallMarginEnd"/>
         <Button
            text="{i18n>showHelloButtonText}"
            press=".onShowHello"
            class="myCustomButton"/>
         <Input
            value="{/recipient/name}"
            valueLiveUpdate="true"
            width="60%"/>
           <FormattedText
              htmlText="Hello {/recipient/name}"
              class="sapUiSmallMargin sapThemeHighlight-asColor myCustomText"/>
      </content>
   </Panel>
</mvc:View>
```

We add an icon to the button that opens the dialog. The `sap-icon://` protocol is indicating that an icon from the icon font should be loaded. The identifier `world` is the readable name of the icon in the icon font.

> → Tip
>
> You can look up other icons using the *Icon Explorer* tool in the Demo Kit.
>
> To call any icon, use its name as listed in the *Icon Explorer* in `sap-icon://`*<iconname>*.

webapp/view/HelloDialog.fragment.xml

```
<core:FragmentDefinition
   xmlns="sap.m"
   xmlns:core="sap.ui.core" >
   <Dialog
      id="helloDialog"
      title ="Hello {/recipient/name}">
```

```
      <content>
         <core:Icon
            src="sap-icon://hello-world"
            size="8rem"
            class="sapUiMediumMargin"/>
      </content>
      <beginButton>
         <Button
            text="{i18n>dialogCloseButtonText}"
            press=".onCloseDialog"/>
      </beginButton>
   </Dialog>
</core:FragmentDefinition>
```

In the dialog fragment, we add an icon control to the content aggregation of the dialog. Luckily, the icon font also comes with a “Hello World” icon that is perfect for us here. We also define the size of the icon and set a medium margin on it.

Conventions

- Always use icon fonts rather than images wherever possible, as they are scalable without quality loss (vector graphics) and do not need to be loaded separately.

API Reference: `sap.ui.core.Icon`
Samples: `sap.ui.core.Icon`

Step 19: Reuse Dialogs

In this step, we expand our reuse concept and invoke the dialog at component level.

In step 16, we created a dialog as fragment, to make it reusable across views or across our whole app. But we placed the logic for retrieving the dialog instance and for opening and closing it respectively in the controller of the `HelloPanel` view. Sticking to this approach would require copying and pasting the code to the controller of each view that needs our dialog. This would cause an undesired code redundancy which we want to avoid.

In this step, we implement the solution to this problem: We expand our reuse concept and invoke the dialog at component level.

Preview

Figure 24: The dialog is now opened by the component (no visual changes to last step)

Coding

You can view and download all files at Walkthrough - Step 19.

webapp/Component.js

```
sap.ui.define([
    "sap/ui/core/UIComponent",
    "sap/ui/model/json/JSONModel",
    "./controller/HelloDialog"
], function (UIComponent, JSONModel, HelloDialog) {
    "use strict";
    return UIComponent.extend("sap.ui.demo.walkthrough.Component", {
        metadata : {
            manifest : "json"
        },
        init : function () {
            // call the init function of the parent
            UIComponent.prototype.init.apply(this, arguments);
            // set data model
            var oData = {
                recipient : {
                    name : "World"
                }
            };
            var oModel = new JSONModel(oData);
            this.setModel(oModel);
            // set dialog
            this._helloDialog = new HelloDialog(this.getRootControl());
        },

        exit : function() {
            this._helloDialog.destroy();
            delete this._helloDialog;
        },

        openHelloDialog : function () {
            this._helloDialog.open();
```

```
        }
    });
});
```

The dialog instantiation is refactored to a new helper object which is stored in a private property of the component. For instantiation of the helper object, we have to pass the view instance to which the dialog is added (see method call `addDependent` in the implementation of the helper object `HelloDialog.js` below).

We want to connect the reuse dialog to the lifecycle of the root view of the app, so we pass an instance of the root view on to the constructor. It can be retrieved by calling the `getRootControl` method of the component.

> **i** Note
>
> As defined in parameter `rootView` in the `manifest.json` file, our root view is `sap.ui.demo.walkthrough.view.App`. From the component, the root view can be retrieved at runtime by accessing the `rootControl` aggregation.

To be able to open the dialog from other controllers as well, we implement a reuse function `openHelloDialog` which calls the `open` method of our helper object. By doing so, we also decouple the implementation details of the reuse dialog from the application coding.

Up to this point we added the new property `_helloDialog` to the component and assigned an instance of the `HelloDialog` object to it. We want to make sure that the memory allocated for this helper object is freed up when the component is destroyed. Otherwise our application may cause memory leaks.

To do so, we use the `exit` hook. The SAPUI5 framework calls the function assigned to `exit` when destroying the component. We call the destroy function of `HelloDialog` to clean up the helper class and end its lifecycle. Nevertheless, the instance itself would still exist in the browser memory. Therefore we delete our reference to the `HelloDialog` instance by calling `delete this._helloDialog` and the garbage collection of the browser can clean up its memory.

> **i** Note
>
> We don't have to destroy the instance of `JSONModel` that we created, because we assigned it to the component with the `setModel` function. The SAPUI5 framework will destroy it together with the component.

webapp/controller/HelloDialog.js (New)

```
sap.ui.define([
    "sap/ui/base/ManagedObject",
    "sap/ui/core/Fragment"
], function (ManagedObject, Fragment) {
    "use strict";

    return
ManagedObject.extend("sap.ui.demo.walkthrough.controller.HelloDialog", {

        constructor : function (oView) {
            this._oView = oView;
        },

        exit : function () {
```

```
            delete this._oView;
        },

        open : function () {
            var oView = this._oView;

            // create dialog lazily
            if (!oView.byId("helloDialog")) {
                var oFragmentController = {
                    onCloseDialog : function () {
                        oView.byId("helloDialog").close();
                    }
                };
                // load asynchronous XML fragment
                Fragment.load({
                    id: oView.getId(),
                    name: "sap.ui.demo.walkthrough.view.HelloDialog",
                    controller: oFragmentController
                }).then(function (oDialog) {
                    // connect dialog to the root view of this component
(models, lifecycle)
                    oView.addDependent(oDialog);
                    oDialog.open();
                });
            } else {
                oView.byId("helloDialog").open();
            }
        }

    });

});
```

The implementation of the `HelloDialog` reuse object extends an `sap.ui.base.ManagedObject` object to inherit some of the core functionality of SAPUI5.

Our `open` method is refactored from the `HelloPanel` controller and instantiates our dialog fragment as in the previous steps.

> **i Note**
>
> We do not pass a controller as third parameter to function `sap.ui.xmlfragment` but a local helper object `oFragmentContoller` which included the needed event handler function `onCloseDialog` for the fragment.

The `open` method now contains our dialog instantiation. The first time the `open` method is called, the dialog is instantiated. The `oView` argument of this method is used to connect the current view to the dialog. We will call the `open` method of this object later in the controller.

The `onCloseDialog` event handler is simply moved from the `HelloPanel` controller to the reuse object.

We also add an `exit` function, just like we did in the component, that will be called automatically when the object is being destroyed. To free up all allocated memory in the helper object, we delete the property that holds the reference to the view. The view itself will be destroyed by the component, so we don't need to take care for that.

webapp/controller/HelloPanel.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageToast"
], function (Controller, MessageToast) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.HelloPanel", {
        onShowHello : function () {
            // read msg from i18n model
            var oBundle = this.getView().getModel("i18n").getResourceBundle();
            var sRecipient = this.getView().getModel().getProperty("/recipient/
name");
            var sMsg = oBundle.getText("helloMsg", [sRecipient]);
            // show message
            MessageToast.show(sMsg);
        },
        onOpenDialog : function () {
            this.getOwnerComponent().openHelloDialog();
        }
    });
});
```

The `onOpenDialog` method now accesses its component by calling the helper method `getOwnerComponent`. When calling the open method of the reuse object we pass in the current view to connect it to the dialog.

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    displayBlock="true">
    <Shell>
        <App class="myAppDemoWT">
            <pages>
                <Page title="{i18n>homePageTitle}">
                    <headerContent>
                        <Button
                            icon="sap-icon://hello-world"
                            press=".onOpenDialog"/>
                    </headerContent>
                    <content>
                        <mvc:XMLView
viewName="sap.ui.demo.walkthrough.view.HelloPanel"/>
                    </content>
                </Page>
            </pages>
        </App>
    </Shell>
</mvc:View>
```

We add a button to the header area of the app view to show the reuse of the hello world dialog. When pressing the button the dialog will be opened as with the button that we previously created in the panel.

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function (Controller) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.App", {
        onOpenDialog : function () {
            this.getOwnerComponent().openHelloDialog();
        }
    });
});
```

We add the method `onOpenDialog` also to the app controller so that the dialog will open with a reference to the current view.

Conventions

- Put all assets that are used across multiple controllers in separate modules.

Step 20: Aggregation Binding

Now that we have established a good structure for our app, it's time to add some more functionality. We start exploring more features of data binding by adding some invoice data in JSON format that we display in a list below the panel.

Preview

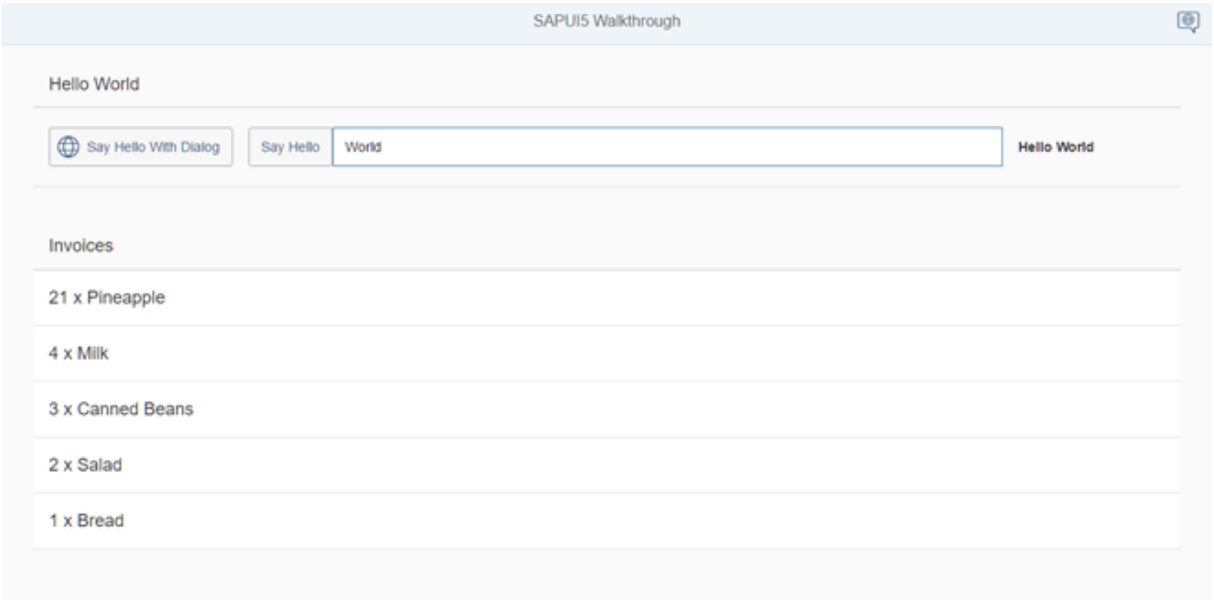

Figure 25: A list of invoices is displayed below the panel

Coding

You can view and download all files at Walkthrough - Step 20.

webapp/Invoices.json (New)

```
{
  "Invoices": [
    {
      "ProductName": "Pineapple",
      "Quantity": 21,
      "ExtendedPrice": 87.2000,
      "ShipperName": "Fun Inc.",
      "ShippedDate": "2015-04-01T00:00:00",
      "Status": "A"
    },
    {
      "ProductName": "Milk",
      "Quantity": 4,
```

```
      "ExtendedPrice": 9.99999,
      "ShipperName": "ACME",
      "ShippedDate": "2015-02-18T00:00:00",
      "Status": "B"
    },
    {
      "ProductName": "Canned Beans",
      "Quantity": 3,
      "ExtendedPrice": 6.85000,
      "ShipperName": "ACME",
      "ShippedDate": "2015-03-02T00:00:00",
      "Status": "B"
    },
    {
      "ProductName": "Salad",
      "Quantity": 2,
      "ExtendedPrice": 8.8000,
      "ShipperName": "ACME",
      "ShippedDate": "2015-04-12T00:00:00",
      "Status": "C"
    },
    {
      "ProductName": "Bread",
      "Quantity": 1,
      "ExtendedPrice": 2.71212,
      "ShipperName": "Fun Inc.",
      "ShippedDate": "2015-01-27T00:00:00",
      "Status": "A"
    }
  ]
}
```

The `invoices` file simply contains five invoices in a JSON format that we can use to bind controls against them in the app. JSON is a very lightweight format for storing data and can be directly used as a data source for SAPUI5 applications.

webapp/manifest.json

```
{
…
  "sap.ui5": {
    "rootView": "sap.ui.demo.walkthrough.view.App",
[…]
    "models": {
      "i18n": {
        "type": "sap.ui.model.resource.ResourceModel",
        "settings": {
          "bundleName": "sap.ui.demo.walkthrough.i18n.i18n"
        }
      },
      "invoice": {
        "type": "sap.ui.model.json.JSONModel",
        "uri": "Invoices.json"
      }
    }
  }
}
```

We add a new model `invoice` to the `sap.ui5` section of the descriptor. This time we want a JSONModel, so we set the type to `sap.ui.model.json.JSONModel`. The `uri` key is the path to our test data relative to the component. With this little configuration our component will automatically instantiate a new `JSONModel` which

loads the invoice data from the `Invoices.json` file. Finally, the instantiated `JSONModel` is put onto the component as a named model invoice. The named model is then visible throughout our app.

> **i Note**
>
> Automatic model instantiation is only available as of SAPUI5 version 1.30. If you are using an older version, you can manually instantiate the resource bundle and other models of the app in the `onInit` method of the `Component.js` file as we did for the resource bundle in Step 9: Component Configuration [page 88].

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    displayBlock="true">
    <Shell>
        <App class="myAppDemoWT">
            <pages>
                <Page title="{i18n>homePageTitle}">
                    <headerContent>
                        <Button
                            icon="sap-icon://hello-world"
                            press=".onOpenDialog"/>
                    </headerContent>
                    <content>
                        <mvc:XMLView
viewName="sap.ui.demo.walkthrough.view.HelloPanel"/>
                        <mvc:XMLView
viewName="sap.ui.demo.walkthrough.view.InvoiceList"/>
                    </content>
                </Page>
            </pages>
        </App>
    </Shell>
</mvc:View>
```

In the app view we add a second view to display our invoices below the panel.

webapp/view/InvoiceList.view.xml (New)

```
<mvc:View
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <List
      headerText="{i18n>invoiceListTitle}"
      class="sapUiResponsiveMargin"
      width="auto"
      items="{invoice>/Invoices}" >
      <items>
         <ObjectListItem
            title="{invoice>Quantity} x {invoice>ProductName}"/>
      </items>
   </List>
</mvc:View>
```

The new view is displaying a list control with a custom header text. The item aggregation of the list is bound to the root path `Invoices` of the JSON data. And since we defined a named model, we have to prefix each binding definition with the identifier `invoice>`.

In the `items` aggregation, we define the template for the list that will be automatically repeated for each invoice of our test data. More precisely, we use an `ObjectListItem` to create a control for each aggregated child of the `items` aggregation. The `title` property of the list item is bound to properties of a single invoice. This is achieved by defining a relative path (without `/` in the beginning). This works because we have bound the `items` aggregation via `items={invoice>/Invoices}` to the invoices.

webapp/i18n/i18n.properties

```
# App Descriptor
appTitle=Hello World
appDescription=A simple walkthrough app that explains the most important
concepts of SAPUI5
# Hello Panel
showHelloButtonText=Say Hello
helloMsg=Hello {0}
homePageTitle=Walkthrough
helloPanelTitle=Hello World
openDialogButtonText=Say Hello With Dialog
dialogCloseButtonText=Ok
# Invoice List
invoiceListTitle=Invoices
```

In the text bundle the title of the list is added.

Samples: `sap.m.List`
List Binding (Aggregation Binding) [page 828]

Step 21: Data Types

The list of invoices is already looking nice, but what is an invoice without a price assigned? Typically prices are stored in a technical format and with a '`.`' delimiter in the data model. For example, our invoice for pineapples has the calculated price `87.2` without a currency. We are going to use the SAPUI5 data types to format the price properly, with a locale-dependent decimal separator and two digits after the separator.

Preview

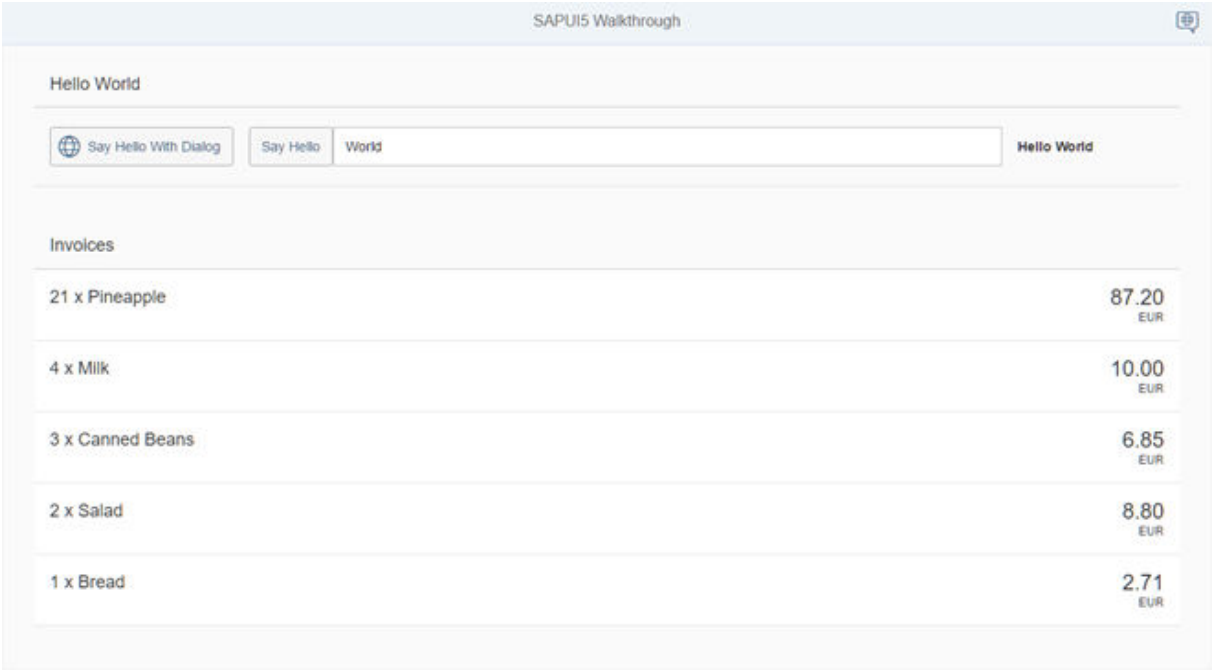

Figure 26: The list of invoices with prices and number units

Coding

You can view and download all files at Walkthrough - Step 21.

webapp/view/InvoiceList.view.xml

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <List
      headerText="{i18n>invoiceListTitle}"
      class="sapUiResponsiveMargin"
      width="auto"
      items="{invoice>/Invoices}">
      <items>
         <ObjectListItem
        title="{invoice>Quantity} x {invoice>ProductName}"
        number="{
            parts: [{path: 'invoice>ExtendedPrice'}, {path: 'view>/currency'}],
            type: 'sap.ui.model.type.Currency',
            formatOptions: {
                showMeasure: false
            }
        }"
        numberUnit="{view>/currency}"/>
    </items>
   </List>
```

```
</mvc:View>
```

We add a price to our invoices list in the view by adding the `number` and `numberUnit` attributes to the `ObjectListItem` control, then we apply the currency data type on the number by setting the `type` attribute of the binding syntax to `sap.ui.model.type.Currency`.

As you can see above, we are using a special binding syntax for the `number` property of the `ObjectListItem`. This binding syntax makes use of so-called "Calculated Fields", which allows the binding of multiple properties from different models to a single property of a control. The properties bound from different models are called “parts”. In the example above, the property of the control is `number` and the bound properties (“parts”) retrieved from two different models are `invoice>ExtendedPrice` and `view>/currency`.

We want to display the price in Euro, and typically the currency is part of our data model on the back end. In our case this is not the case, so we need to define it directly in the app. We therefore add a controller for the invoice list, and use the `currency` property as the second part of our binding syntax. The `Currency` type will handle the formatting of the price for us, based on the currency code. In our case, the price is displayed with 2 decimals.

Additionally, we set the formatting option `showMeasure` to `false`. This hides the currency code in the property `number`, because it is passed on to the `ObjectListItem` control as a separate property `numberUnit`.

webapp/controller/InvoiceList.controller.js (New)

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel"
], function (Controller, JSONModel) {
    "use strict";

    return Controller.extend("sap.ui.demo.walkthrough.controller.InvoiceList", {

        onInit : function () {
            var oViewModel = new JSONModel({
                currency: "EUR"
            });
            this.getView().setModel(oViewModel, "view");
        }

    });
});
```

To be able to access the currency code that is not part of our data model, we define a view model in the controller of the invoice list. It is a simple JSON model with just one key `currency` and the value `EUR`. This can be bound to the formatter of the number field. View models can hold any configuration options assigned to a control to bind properties such as the visibility.

Conventions

- Use data types instead of custom formatters whenever possible.

Formatting, Parsing, and Validating Data [page 854]
API Reference: `sap.ui.model.type`
API Reference: `sap.ui.model.type.Currency`
Samples: `sap.ui.model.type.Currency`

Step 22: Expression Binding

Sometimes the predefined types of SAPUI5 are not flexible enough and you want to do a simple calculation or formatting in the view - that is where expressions are really helpful. We use them to format our price according to the current number in the data model.

Preview

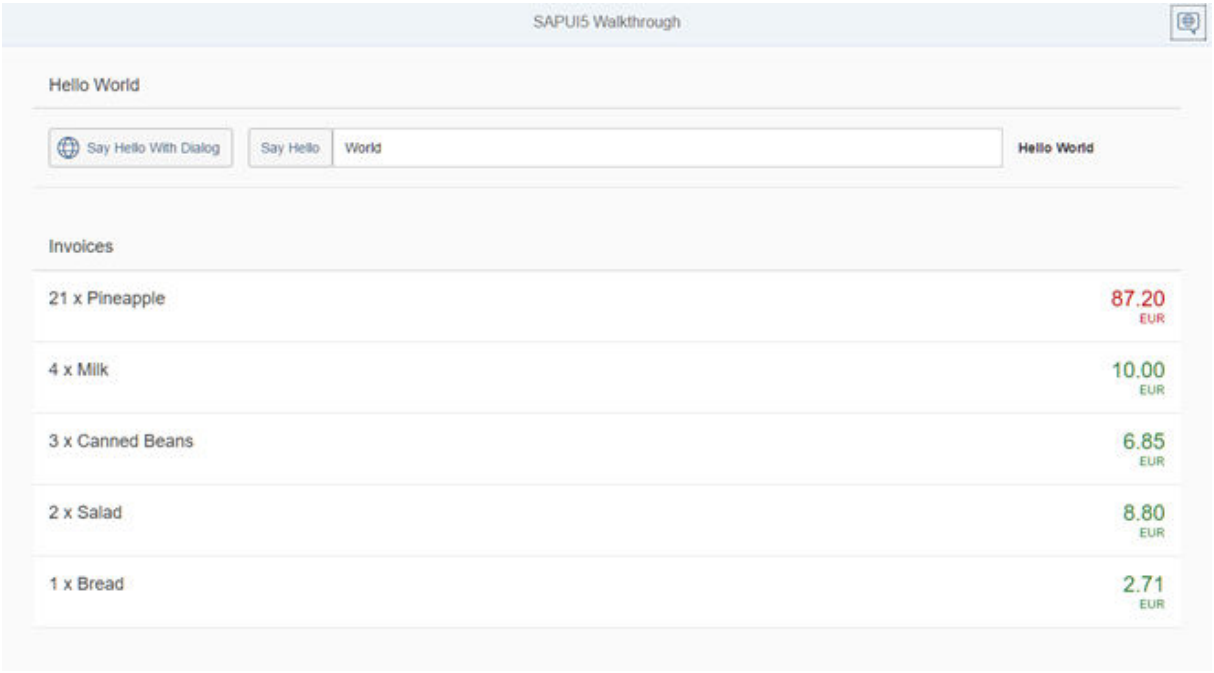

Figure 27: The price is now formatted according to its number

Coding

You can view and download all files at Walkthrough - Step 22.

webapp/view/InvoiceList.view.xml

```
<mvc:View
controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <List
      headerText="{i18n>invoiceListTitle}"
      class="sapUiResponsiveMargin"
      width="auto"
      items="{invoice>/Invoices}" >
      <items>
         <ObjectListItem
            title="{invoice>Quantity} x {invoice>ProductName}"
            number="{
        parts: [{path: 'invoice>ExtendedPrice'}, {path: 'view>/currency'}],
        type: 'sap.ui.model.type.Currency',
        formatOptions: {
            showMeasure: false
        }
        }"
        numberUnit="{view>/currency}"
            numberState="{= ${invoice>ExtendedPrice} > 50 ? 'Error' :
'Success' }"/>
      </items>
   </List>
</mvc:View>
```

We add the property `numberState` in our declarative view and introduce a new binding syntax that starts with = inside the brackets. This symbol is used to initiate a new binding syntax, it's called an expression and can do simple calculation logic like the ternary operator shown here.

The condition of the operator is a value from our data model. A model binding inside an expression binding has to be escaped with the `$` sign as you can see in the code. We set the state to `'Error'` (the number will appear in red) if the price is higher than 50 and to `'Success'` (the number will appear in green) otherwise.

Expressions are limited to a particular set of operations that help formatting the data such as Math expression, comparisons, and such. You can lookup the possible operations in the documentation.

Conventions

- Only use expression binding for trivial calculations.

Related Information

Expression Binding [page 845]

Step 23: Custom Formatters

If we want to do a more complex logic for formatting properties of our data model, we can also write a custom formatting function. We will now add a localized status with a custom formatter, because the status in our data model is in a rather technical format.

Preview

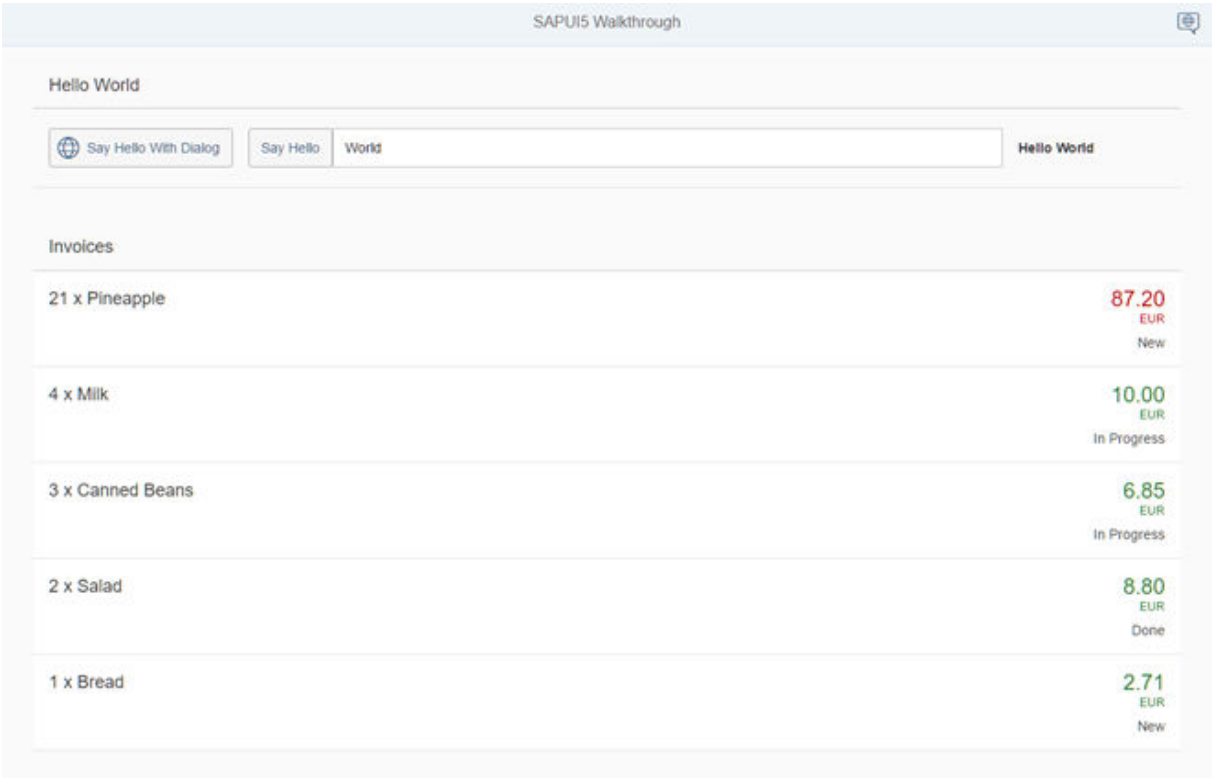

Figure 28: A status is now displayed with a custom formatter

Coding

You can view and download all files at Walkthrough - Step 23.

webapp/model/formatter.js (New)

```
sap.ui.define([], function () {
    "use strict";
    return {
        statusText: function (sStatus) {
            var resourceBundle =
this.getView().getModel("i18n").getResourceBundle();
```

```
            switch (sStatus) {
                case "A":
                    return resourceBundle.getText("invoiceStatusA");
                case "B":
                    return resourceBundle.getText("invoiceStatusB");
                case "C":
                    return resourceBundle.getText("invoiceStatusC");
                default:
                    return sStatus;
            }
        }
    };
});
```

We create a new folder `model` in our app project. The new `formatter` file is placed in the model folder of the app, because formatters are working on data properties and format them for display on the UI. So far we did not have any model-related artifacts, except for the `Invoices.json` file, we will now add the folder `webapp/model` to our app. This time we do not extend from any base object but just return a JavaScript object with our `formatter` functions inside the `sap.ui.define` call.

Function `statusText` gets the technical status from the data model as input parameter and returns a human-readable text that is read from the `resourceBundle` file.

webapp/controller/InvoiceList.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "../model/formatter"
], function (Controller, JSONModel, formatter) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.InvoiceList", {
        formatter: formatter,
        onInit : function () {
            var oViewModel = new JSONModel({
                currency: "EUR"
            });
            this.getView().setModel(oViewModel, "view");
        }
    });
});
```

To load our formatter functions, we have to add it to the `InvoiceList.controller.js`. In this controller, we first add a dependency to our custom `formatter` module. The controller simply stores the loaded formatter functions in the local property `formatter` to be able to access them in the view.

webapp/view/InvoiceList.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <List
            headerText="{i18n>invoiceListTitle}"
```

```
        class="sapUiResponsiveMargin"
        width="auto"
        items="{invoice>/Invoices}">
        <items>
            <ObjectListItem
                title="{invoice>Quantity} x {invoice>ProductName}"
                number="{
                    parts: [{path: 'invoice>ExtendedPrice'}, {path: 'view>/
currency'}],
                    type: 'sap.ui.model.type.Currency',
                    formatOptions: {
                        showMeasure: false
                    }
                }"
                numberUnit="{view>/currency}"
                numberState="{=    ${invoice>ExtendedPrice} > 50 ? 'Error' :
'Success' }">
                <firstStatus>
                    <ObjectStatus text="{
                        path: 'invoice>Status',
                        formatter: '.formatter.statusText'
                    }"/>
                </firstStatus>
            </ObjectListItem>
        </items>
    </List>
</mvc:View>
```

We add a status using the `firstStatus` aggregation to our `ObjectListItem` that will display the status of our invoice. The custom formatter function is specified with the reserved property `formatter` of the binding syntax. A `"."` in front of the formatter name means that the function is looked up in the controller of the current view. There we defined a property `formatter` that holds our formatter functions, so we can access it by `.formatter.statusText`.

webapp/i18n/i18n.properties

```
# App Descriptor
appTitle=Hello World
appDescription=A simple walkthrough app that explains the most important
concepts of SAPUI5
# Hello Panel
showHelloButtonText=Say Hello
helloMsg=Hello {0}
homePageTitle=Walkthrough
helloPanelTitle=Hello World
openDialogButtonText=Say Hello With Dialog
dialogCloseButtonText=Ok
# Invoice List
invoiceListTitle=Invoices
invoiceStatusA=New
invoiceStatusB=In Progress
invoiceStatusC=Done
```

We add three new entries to the resource bundle that reflect our translated status texts. These texts are now displayed below the `number` attribute of the `ObjectListItem` dependent on the status of the invoice.

Related Information

Formatting, Parsing, and Validating Data [page 854]

Step 24: Filtering

In this step, we add a search field for our product list and define a filter that represents the search term. When searching, the list is automatically updated to show only the items that match the search term.

Preview

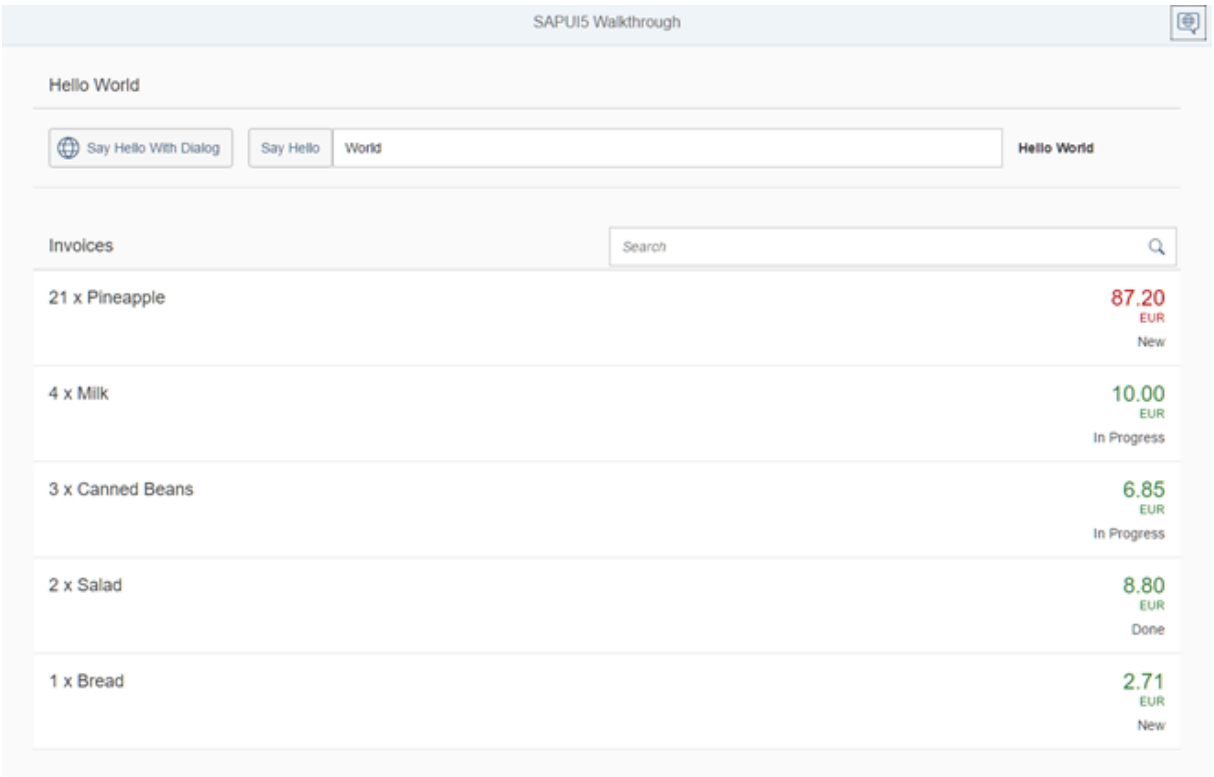

Figure 29: A search field is displayed above the list

Coding

You can view and download all files at Walkthrough - Step 24.

webapp/view/InvoiceList.view.xml

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <List
      id="invoiceList"
      class="sapUiResponsiveMargin"
      width="auto"
      items="{invoice>/Invoices}" >
      <headerToolbar>
         <Toolbar>
            <Title text="{i18n>invoiceListTitle}"/>
            <ToolbarSpacer/>
            <SearchField width="50%" search=".onFilterInvoices"/>
         </Toolbar>
      </headerToolbar>
      <items>
         <ObjectListItem>
        …
         </ObjectListItem/>
      </items>
   </List>
</mvc:View>
```

The view is extended by a search control that we add to the list of invoices. We also need to specify an ID `invoiceList` for the list control to be able to identify the list from the event handler function `onFilterInvoices` that we add to the search field. In addition, the search field is part of the list header and therefore, each change on the list binding will trigger a rerendering of the whole list, including the search field.

The `headerToolbar` aggregation replaces the simple `title` property that we used before for our list header. A toolbar control is way more flexible and can be adjusted as you like. We are now displaying the title on the left side with a `sap.m.Title` control, a spacer, and the `sap.m.SearchField` on the right.

webapp/controller/InvoiceList.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "../model/formatter",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator"
], function (Controller, JSONModel, formatter, Filter, FilterOperator) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.InvoiceList", {
        formatter: formatter,
        onInit : function () {
            var oViewModel = new JSONModel({
                currency: "EUR"
            });
            this.getView().setModel(oViewModel, "view");
        },
        onFilterInvoices : function (oEvent) {

            // build filter array
            var aFilter = [];
            var sQuery = oEvent.getParameter("query");
```

```
            if (sQuery) {
                aFilter.push(new Filter("ProductName", FilterOperator.Contains,
sQuery));
            }

            // filter binding
            var oList = this.byId("invoiceList");
            var oBinding = oList.getBinding("items");
            oBinding.filter(aFilter);
        }
    });
});
```

We load two new dependencies for the filtering. The filter object will hold our configuration for the filter action and the `FilterOperator` is a helper type that we need in order to specify the filter.

In the `onFilterInvoices` function we construct a filter object from the search string that the user has typed in the search field. Event handlers always receive an event argument that can be used to access the parameters that the event provides. In our case the search field defines a parameter `query` that we access by calling `getParameter("query")` on the `oEvent` parameter.

If the query is not empty, we add a new filter object to the still empty array of filters. However, if the query is empty, we filter the binding with an empty array. This makes sure that we see all list elements again. We could also add more filters to the array, if we wanted to search more than one data field. In our example, we just search in the `ProductName` path and specify a filter operator that will search for the given query string.

The list is accessed with the ID that we have specified in the view, because the control is automatically prefixed by the view ID, we need to ask the view for the control with the helper function `byId`. On the list control we access the binding of the aggregation `items` to filter it with our newly constructed filter object. This will automatically filter the list by our search string so that only the matching items are shown when the search is triggered. The filter operator `FilterOperator.Contains` is **not** case-sensitive.

API Reference: `sap.m.SearchField`

Step 25: Sorting and Grouping

To make our list of invoices even more user-friendly, we sort it alphabetically instead of just showing the order from the data model. Additionally, we introduce groups and add the company that ships the products so that the data is easier to consume.

Preview

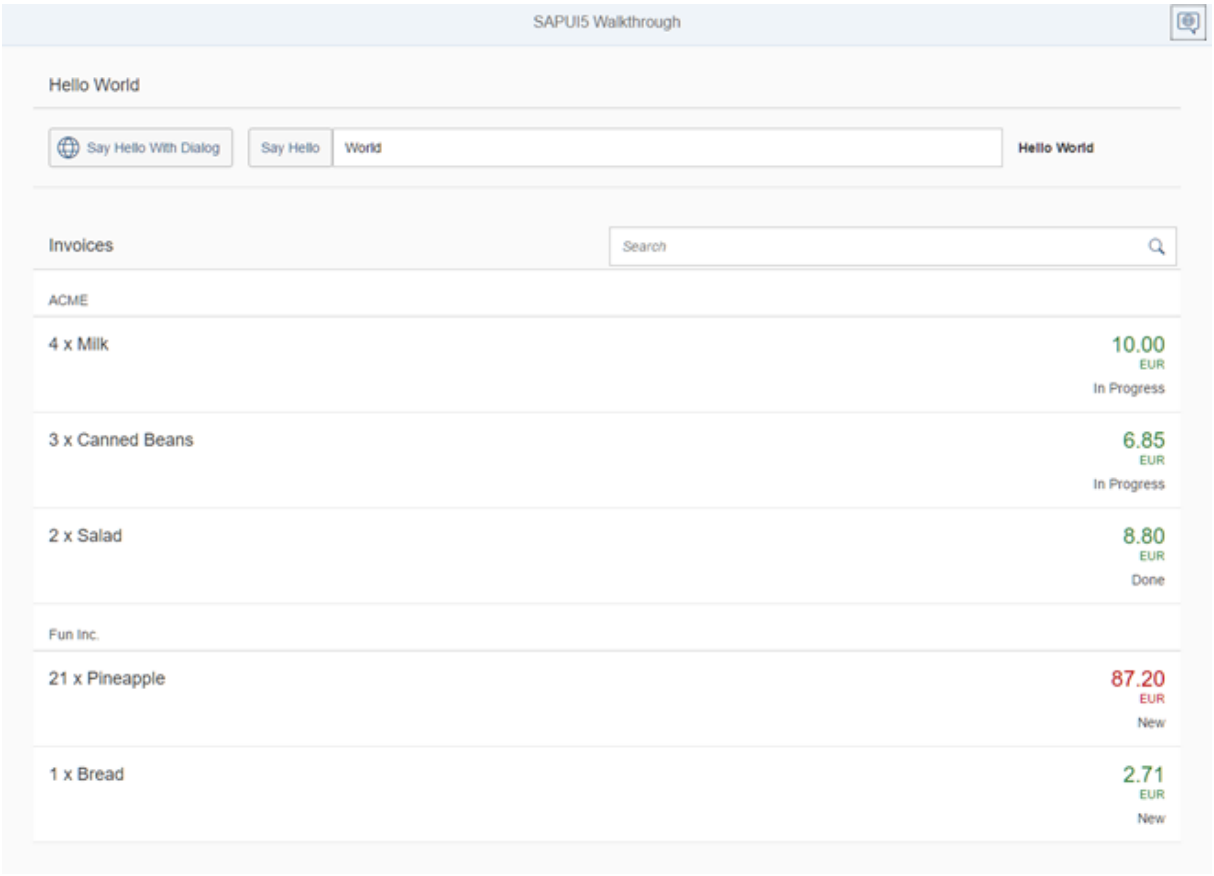

Figure 30: The list is now sorted and grouped by the shipping company

Coding

You can view and download all files at Walkthrough - Step 25.

webapp/view/InvoiceList.view.xml

```
<mvc:View
   controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
   xmlns="sap.m"
```

```
   xmlns:mvc="sap.ui.core.mvc">
   <List
      id="invoiceList"
      class="sapUiResponsiveMargin"
      width="auto"
      items="{
         path : 'invoice>/Invoices',
         sorter : {
            path : 'ProductName'
         }
      }" >
      <headerToolbar>
         ...
      </headerToolbar>
      <items>
         ...
      </items>
   </List>
</mvc:View>
```

We add a declarative sorter to our binding syntax. As usual, we transform the simple binding syntax to the object notation, specify the path to the data, and now add an additional `sorter` property. We specify the data path by which the invoice items should be sorted, the rest is done automatically. By default, the sorting is ascending, but you could also add a property `descending` with the value `true` inside the sorter property to change the sorting order.

If we run the app now we can see a list of invoices sorted by the name of the products.

webapp/view/InvoiceList.view.xml

```
<mvc:View
controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
xmlns="sap.m"
xmlns:mvc="sap.ui.core.mvc">
<List
        id="invoiceList"
        class="sapUiResponsiveMargin"
        width="auto"
        items="{
            path : 'invoice>/Invoices',
            sorter : {
                path : 'ShipperName',
                group : true
            }
        }">
    <headerToolbar>
        <Toolbar>
            <Title text="{i18n>invoiceListTitle}"/>
            <ToolbarSpacer/>
            <SearchField width="50%" search=".onFilterInvoices"/>
        </Toolbar>
    </headerToolbar>
    <items>
        …
    </items>
</List>
</mvc:View>
```

We modify the view and add a different sorter, or better; we change the sorter and set the attribute `group` to true. We also specify the path to the `ShipperName` data field. This groups the invoice items by the shipping company.

As with the sorter, no further action is required. The list and the data binding features of SAPUI5 will do the trick to display group headers automatically and categorize the items in the groups. We could define a custom grouping function if we wanted by setting the `groupHeaderFactory` property, but the result looks already fine.

API Reference: `sap.ui.model.Sorter`
Sample: List - Grouping

Step 26: Remote OData Service

So far we have worked with local JSON data, but now we will access a real OData service to visualize remote data.

In the real world, data often resides on remote servers and is accessed via an OData service. We will add a data source configuration to the manifest and replace the JSONModel type for our `invoice` model with the publicly available Northwind OData service to visualize remote data. You will be surprised how little needs to be changed in order to make this work!

> **i** Note
>
> If you cannot get it to run, don't worry too much, the remaining steps will also work with the local JSON data you have used so far. In Step 27: Mock Server Configuration [page 139], you will learn how to simulate a back-end system to achieve a similar working scenario. However, you should at least read this chapter about remote OData services to learn about non-local data sources.

Preview

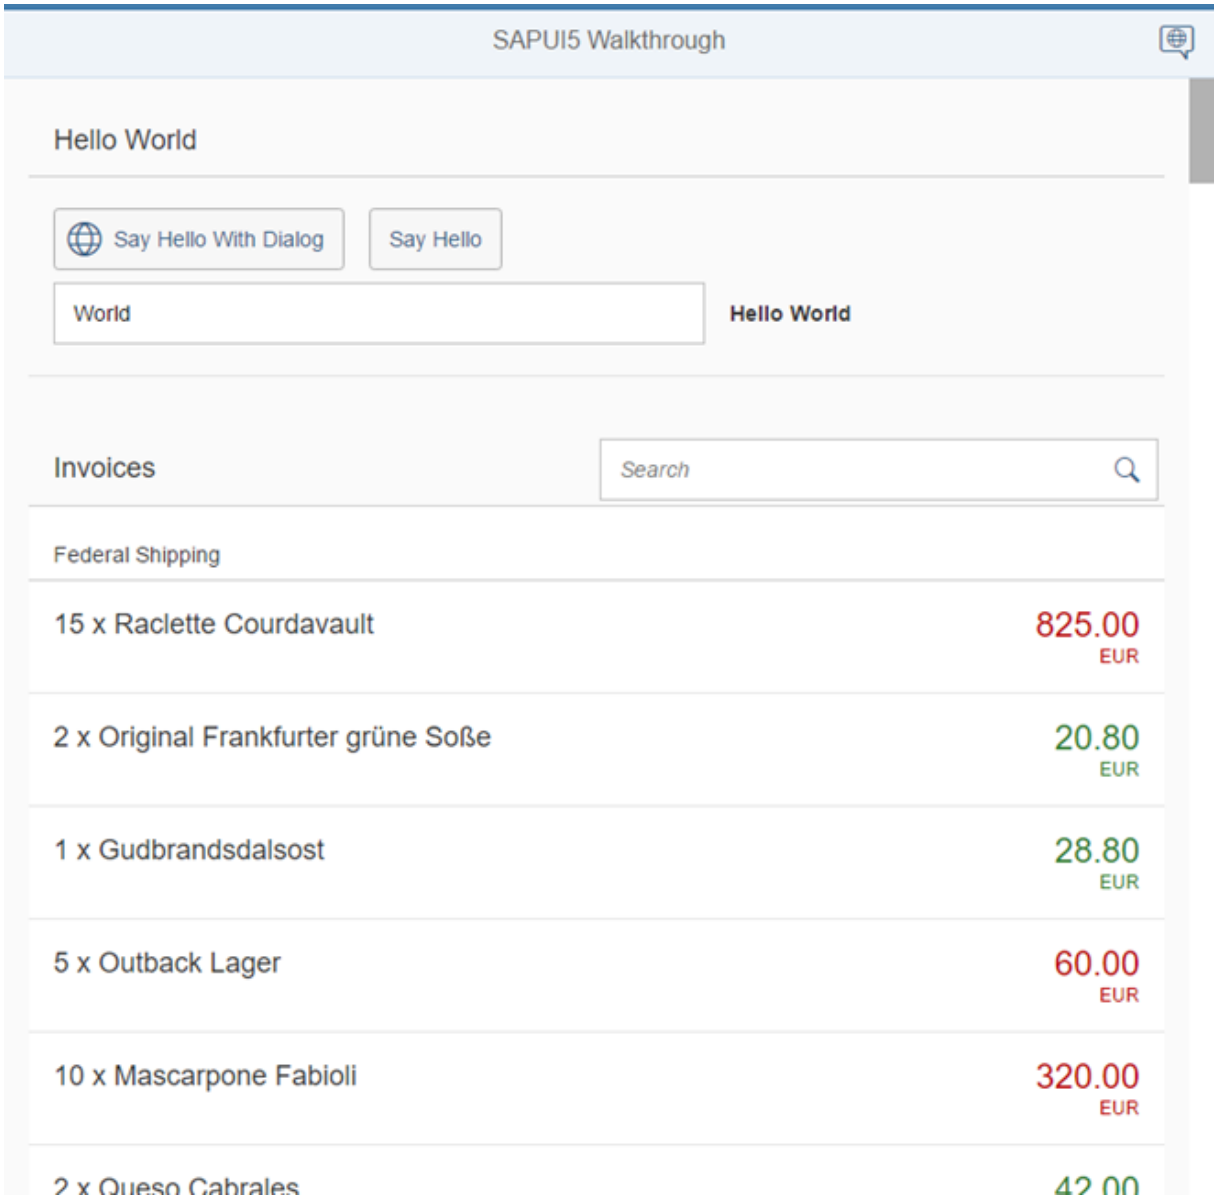

Figure 31: Products from the OData invoices test service are now shown within our app

Coding

You can view and download all files at Walkthrough - Step 26.

webapp/manifest.json

```
{
  "_version": "1.12.0",
```

```
  "sap.app": {
    ...
    "ach": "CA-UI5-DOC",
    "dataSources": {
      "invoiceRemote": {
        "uri": "https://services.odata.org/V2/Northwind/Northwind.svc/",
        "type": "OData",
        "settings": {
          "odataVersion": "2.0"
        }
      }
    }
  },
  "sap.ui": {
    ...
  },
  "sap.ui5": {
    ...
    "models": {
      "i18n": {
        "type": "sap.ui.model.resource.ResourceModel",
        "settings": {
          "bundleName": "sap.ui.demo.walkthrough.i18n.i18n"
        }
      },
      "invoice": {
        "dataSource": "invoiceRemote"
      }
    }
  }
}
```

In the `sap.app` section of the descriptor file, we add a data source configuration. With the `invoiceRemote`, key we specify a configuration object that allows automatic model instantiation. We specify the type of the service (`OData`) and the model version (`2.0`). In this step, we want to use the publicly available Northwind OData service located at `https://services.odata.org/V2/Northwind/Northwind.svc/`. Therefore, the URI points to the official Northwind OData service.

In the `models` section, we replace the content of the `invoice` model. This key is still used as model name when the model is automatically instantiated during the component initialization. However, the `invoiceRemote` value of the `dataSource` key is a reference to the data source section that we specified above. This configuration allows the component to retrieve the technical information for this model during the start-up of the app.

Our component now automatically creates an instance of `sap.ui.model.odata.v2.ODataModel` according to the settings we specified above, and makes it available as a model named `invoice`. When you use the `invoiceRemote` data source, the `ODataModel` fetches the data from the real Northwind OData service. The invoices we receive from the Northwind OData service have identical properties as the JSON data we used previously (except for the `status` property, which is not available in the Northwind OData service).

> **i Note**
>
> If you want to have a default model on the component, you can change the name of the model to an empty string in the descriptor file. Automatically instantiated models can be retrieved by calling `this.getModel` in the component. In the controllers of component-based apps you can call `this.getView().getModel()` to get the automatically instantiated model. For retrieving a named model you have to pass on the model name defined in the descriptor file to `getModel`, that is, in the component you would call `this.getModel("invoice")` to get our automatically generated `invoice` model that we defined in the descriptor.

You can now try to run the app and see what happens - we will see an error related to our new configuration in the console:

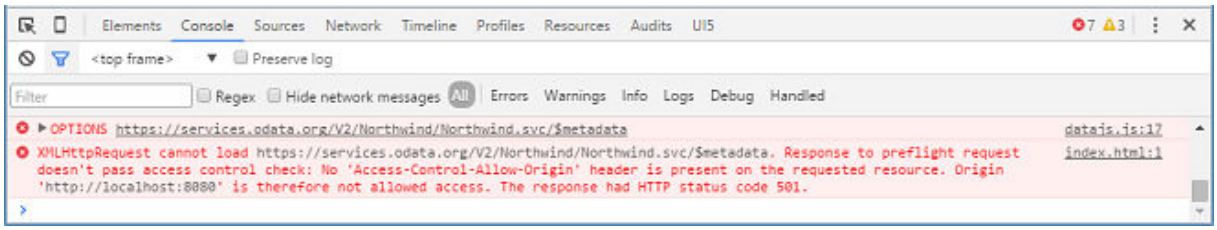

Figure 32: Violations of the same-origin policy in Google Chrome

Due to the so called same-origin policy, browsers deny AJAX requests to service endpoints in case the service endpoint has a different domain/subdomain, protocol, or port than the app. The browser refuses to connect to a remote URL directly for security reasons. Depending on your development environment you have different options to overcome this limitation:

- SAP Web IDE: Configure a destination [page 1392]
- Local Development: Configure a local proxy (CORS anywhere) [page 1394]
- Workaround: Disabling the same-origin policy in the browser [page 1395] (not recommended, only for testing)

First-Aid Kit [page 1386]
Request Fails Due to Same-Origin Policy (Cross-Origin Resource Sharing - CORS) [page 1391]

Step 27: Mock Server Configuration

We just ran our app against a real service, but for developing and testing our app we do not want to rely on the availability of the “real” service or put additional load on the system where the data service is located.

This system is the so-called back-end system that we will now simulate with an SAPUI5 feature called mock server. It serves local files, but it simulates a back-end system more realistically than just loading the local data. We will also change the model instantiation part so that the model is configured in the descriptor and instantiated automatically by SAPUI5. This way, we do not need to take care of the model instantiation in the code.

Preview

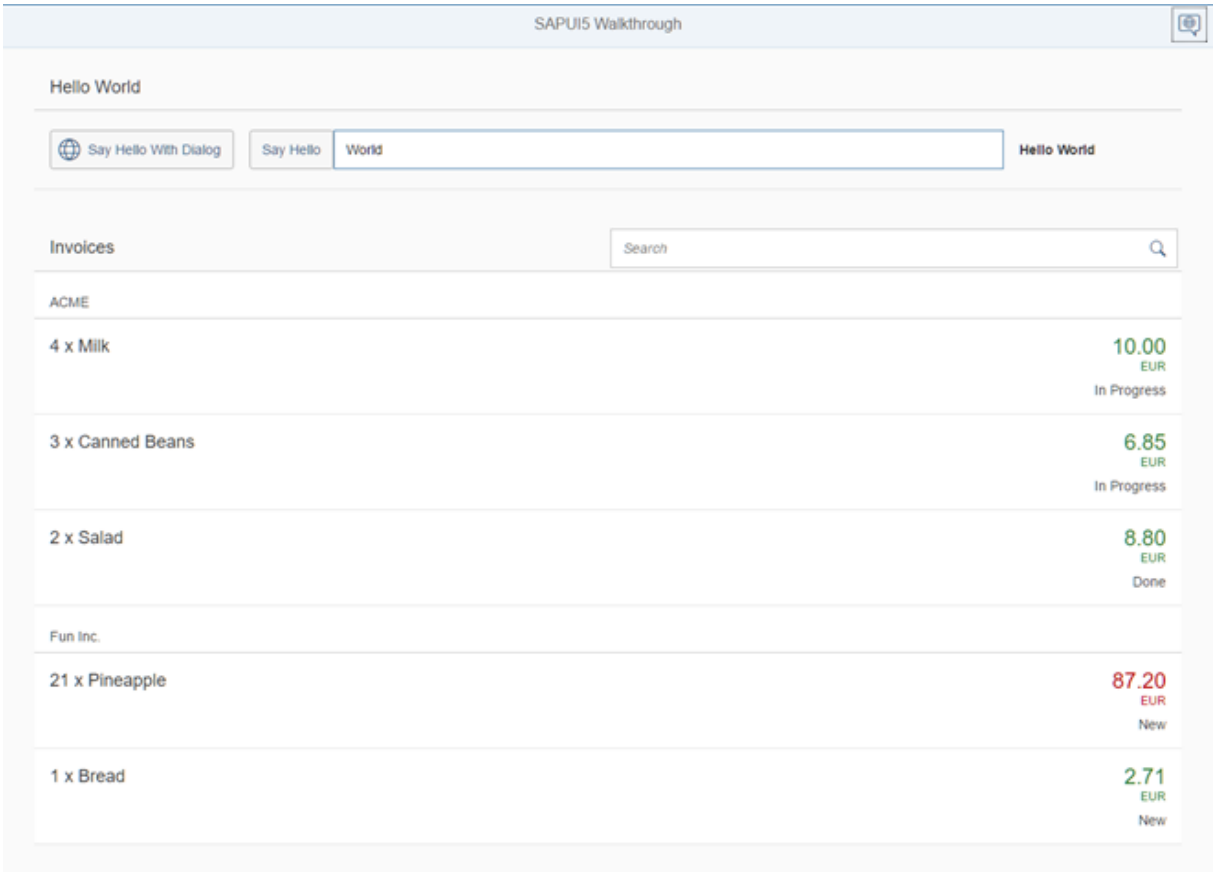

Figure 33: The list of invoices is now served by the Mock Server

Coding

You can view and download all files at Walkthrough - Step 27.

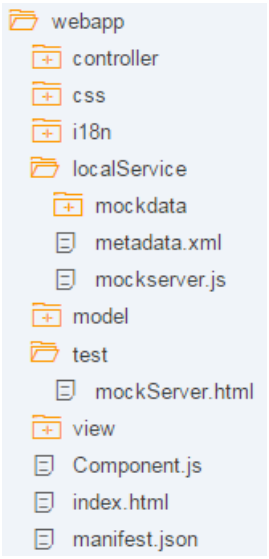

Figure 34: Folder Structure for this Step

The folder structure of our app project is clearly separating test and productive files after this step. The new `test` folder now contains a new HTML page `mockServer.html` which will launch our application in test mode without calling the real service.

The new `localService` folder contains a `metadata.xml` service description file for OData, the `mockserver.js` file that simulates a real service with local data, and the `mockdata` subfolder that contains the local test data (`Invoices.json`).

webapp/test/mockServer.html (New)

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <title>SAPUI5 Walkthrough</title>
    <script
        id="sap-ui-bootstrap"
        src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-libs="sap.m"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.walkthrough": "./"
        }'
        data-sap-ui-oninit="module:sap/ui/core/ComponentSupport"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true">
    </script>
</head>
<body class="sapUiBody" id="content">
    <div data-sap-ui-component data-name="sap.ui.demo.walkthrough" data-
id="container" data-settings='{"id" : "walkthrough"}'></div>
</body>
</html>
```

We copy the `index.html` to a separate file in the `webapp/test` folder and name it `mockServer.html`. We will now use this file to run our app in test mode with mock data loaded from a JSON file. Test pages should not

be placed in the application root folder but in a subfolder called `test` to clearly separate productive and test coding.

From this point on, you have two different entry pages: One for the real "connected" app (`index.html`) and one for local testing (`mockServer.html`). You can freely decide if you want to do the next steps on the real service data or on the local data within the app.

> **i** Note
>
> If no connection to the real service is available or the proxy configuration from the previous step does not work, you can always use the `mockServer.html` file. This will display the app with simulated test data. The `index.html` file will always load the data from a remote server. If the request fails, the list of invoices will stay empty.

webapp/test/mockServer.html

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <meta name="viewport" content="width=device-width, initial-scale=1.0">
    <title>SAPUI5 Walkthrough - Test Page</title>
    <script
        id="sap-ui-bootstrap"
        src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.walkthrough": "../"
        }'
        data-sap-ui-oninit="module:sap/ui/demo/walkthrough/test/initMockServer"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true">
    </script>
</head>
<body class="sapUiBody" id="content">
    <div data-sap-ui-component data-name="sap.ui.demo.walkthrough" data-
id="container" data-settings='{"id" : "walkthrough"}'></div>
</body>
</html>
```

We modify the `mockServer.html` file and change the page title to distinguish it from the productive start page. In the bootstrap, the `data-sap-ui-resourceroots` property is also changed. The namespace now points to the folder above (`"../"`), because the `mockServer.html` file is now in a subfolder of the `webapp` folder. Instead of loading the app component directly, we now call a script `initMockServer.js`.

webapp/test/initMockServer.js (New)

```
sap.ui.define([
    "../localService/mockserver"
], function (mockserver) {
    "use strict";
```

```
    // initialize the mock server
    mockserver.init();

    // initialize the embedded component on the HTML page
    sap.ui.require(["sap/ui/core/ComponentSupport"]);
});
```

The first dependency is a file called `mockserver.js` that will be located in the `localService` folder later.

The `mockserver` depencency that we are about to implement is our local test server. Its `init` method is immediately called before we load the component. This way we can catch all requests that would go to the "real" service and process them locally by our test server when launching the app with the `mockServer.html` file. The component itself does not "know" that it will now run in test mode.

webapp/localService/mockdata/Invoices.json (New)

```
[
  {
    "ProductName": "Pineapple",
    "Quantity": 21,
    "ExtendedPrice": 87.2000,
    "ShipperName": "Fun Inc.",
    "ShippedDate": "2015-04-01T00:00:00",
    "Status": "A"
  },
  {
    "ProductName": "Milk",
    "Quantity": 4,
    "ExtendedPrice": 9.99999,
    "ShipperName": "ACME",
    "ShippedDate": "2015-02-18T00:00:00",
    "Status": "B"
  },
  {
    "ProductName": "Canned Beans",
    "Quantity": 3,
    "ExtendedPrice": 6.85000,
    "ShipperName": "ACME",
    "ShippedDate": "2015-03-02T00:00:00",
    "Status": "B"
  },
  {
    "ProductName": "Salad",
    "Quantity": 2,
    "ExtendedPrice": 8.8000,
    "ShipperName": "ACME",
    "ShippedDate": "2015-04-12T00:00:00",
    "Status": "C"
  },
  {
    "ProductName": "Bread",
    "Quantity": 1,
    "ExtendedPrice": 2.71212,
    "ShipperName": "Fun Inc.",
    "ShippedDate": "2015-01-27T00:00:00",
    "Status": "A"
  }
]
```

The `Invoices.json` file is similar to our previous file in the `webapp` folder. Just copy the content and remove the outer object structure with the key `invoices` so that the file consists of one flat array of invoice items. This file will automatically be read by our server later in this step.

Remove the old `Invoices.json` file from the `webapp` folder, it is no longer used.

webapp/localService/metadata.xml (New)

```
<edmx:Edmx Version="1.0" xmlns:edmx="http://schemas.microsoft.com/ado/2007/06/
edmx">
    <edmx:DataServices m:DataServiceVersion="1.0" m:MaxDataServiceVersion="3.0"
                       xmlns:m="http://schemas.microsoft.com/ado/2007/08/
dataservices/metadata">
        <Schema Namespace="NorthwindModel" xmlns="http://
schemas.microsoft.com/ado/2008/09/edm">
            <EntityType Name="Invoice">
                <Key>
                    <PropertyRef Name="ProductName"/>
                    <PropertyRef Name="Quantity"/>
                    <PropertyRef Name="ShipperName"/>
                </Key>
                <Property Name="ShipperName" Type="Edm.String" Nullable="false"
MaxLength="40" FixedLength="false"
                          Unicode="true"/>
                <Property Name="ProductName" Type="Edm.String" Nullable="false"
MaxLength="40" FixedLength="false"
                          Unicode="true"/>
                <Property Name="Quantity" Type="Edm.Int16" Nullable="false"/>
                <Property Name="ExtendedPrice" Type="Edm.Decimal" Precision="19"
Scale="4"/>
            </EntityType>
        </Schema>
        <Schema Namespace="ODataWebV2.Northwind.Model" xmlns="http://
schemas.microsoft.com/ado/2008/09/edm">
            <EntityContainer Name="NorthwindEntities"
m:IsDefaultEntityContainer="true" p6:LazyLoadingEnabled="true"
                             xmlns:p6="http://schemas.microsoft.com/ado/
2009/02/edm/annotation">
                <EntitySet Name="Invoices" EntityType="NorthwindModel.Invoice"/>
            </EntityContainer>
        </Schema>
    </edmx:DataServices>
</edmx:Edmx>
```

The metadata file contains information about the service interface and does not need to be written manually. It can be accessed directly from the "real" service by calling the service URL and adding `$metadata` at the end (e.g. in our case `http://services.odata.org/V2/Northwind/Northwind.svc/$metadata`). The mock server will read this file to simulate the real OData service, and will return the results from our local source files in the proper format so that it can be consumed by the app (either in XML or in JSON format).

For simplicity, we have removed all content from the original Northwind OData metadata document that we do not need in our scenario. We have also added the `status` field to the metadata since it is not available in the real Northwind service.

webapp/localService/mockserver.js (New)

```
sap.ui.define([
    "sap/ui/core/util/MockServer",
    "sap/base/util/UriParameters"
], function (MockServer, UriParameters) {
    "use strict";

    return {
        init: function () {
            // create
            var oMockServer = new MockServer({
                rootUri: "https://services.odata.org/V2/Northwind/Northwind.svc/"
            });

            var oUriParameters = new UriParameters(window.location.href);

            // configure mock server with a delay
            MockServer.config({
                autoRespond: true,
                autoRespondAfter: oUriParameters.get("serverDelay") || 500
            });

            // simulate
            var sPath = "../localService";
            oMockServer.simulate(sPath + "/metadata.xml", sPath + "/mockdata");

            // start
            oMockServer.start();
        }
    };

});
```

Now that we have added the OData service description file `metadata.xml` file, we can write the code to initialize the mock server which will then simulate any OData request to the real Northwind server.

We load the standard SAPUI5 `MockServer` module as a dependency and create a helper object that defines an `init` method to start the server. This method is called before the component initialization in the `mockServer.html` file above. The `init` method creates a `MockServer` instance with the same URL as the real service calls.

The URL in configuration parameter `rootUri` has to be exactly the same as the `uri` that is defined for the data source in the `manifest.json` descriptor file. This can be an absolute or, for example in SAP Web IDE, a relative URL to a destination. The URL will now be served by our test server instead of the real service. Next, we set two global configuration settings that tell the server to respond automatically and introduce a delay of one second to imitate a typical server response time. Otherwise, we would have to call the respond method on the `MockServer` manually to simulate the call.

To simulate a service, we can simply call the `simulate` method on the `MockServer` instance with the path to our newly created `metadata.xml`. This will read the test data from our local file system and set up the URL patterns that will mimic the real service.

Finally, we call start on `oMockServer`. From this point, each request to the URL pattern `rootUri` will be processed by the `MockServer`. If you switch from the `index.html` file to the `mockServer.html` file in the browser, you can now see that the test data is displayed from the local sources again, but with a short delay. The delay can be specified with the URI parameter `serverDelay`, the default value is one second.

This approach is perfect for local testing, even without any network connection. This way your development does not depend on the availability of a remote server, i.e. to run your tests.

Try calling the app with the `index.html` file and the `mockServer.html` file to see the difference. If the real service connection cannot be made, for example when there is no network connection, you can always fall back to the local test page.

Conventions

- The `webapp/test` folder contains non-productive code only.
- Mock data and the script to start the `MockServer` are stored in the `webapp/localService` folder.
- The script to start the `MockServer` is called `mockserver.js`.

Create a Northwind Destination [page 49]

Step 28: Unit Test with QUnit

Now that we have a test folder in the app, we can start to increase our test coverage.

Actually, every feature that we added to the app so far, would require a separate test case. We have totally neglected this so far, so let's add a simple unit test for our custom formatter function from Step 23. We will test if the long text for our status is correct by comparing it with the texts from our resource bundle.

> **i Note**
>
> In this tutorial, we focus on a simple use case for the test implementation. If you want to learn more about QUnit tests, have a look at our Testing [page 368] tutorial, especially Step 2: A First Unit Test [page 376].

Preview

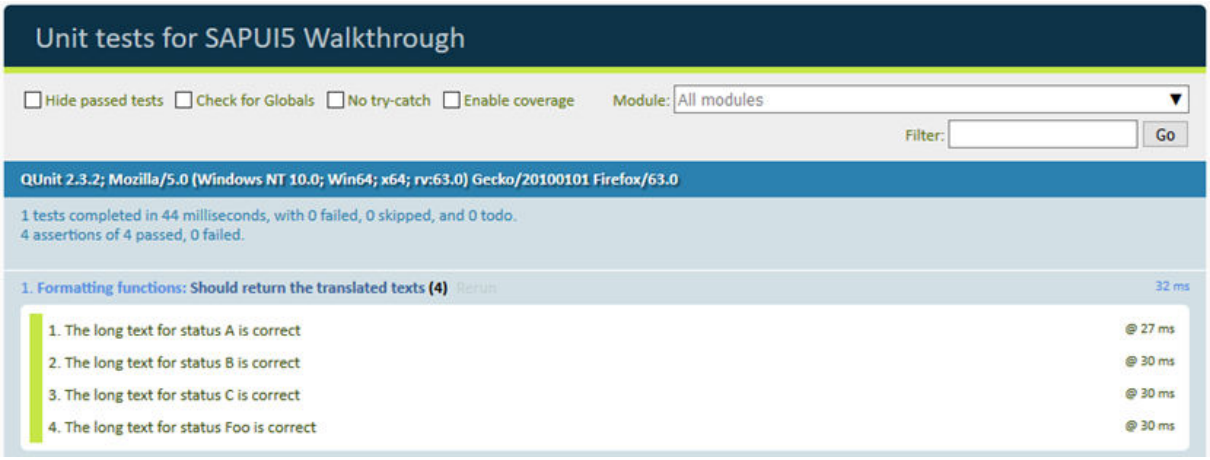

Figure 35: A unit test for our formatters is now available

Coding

You can view and download all files at Walkthrough - Step 28.

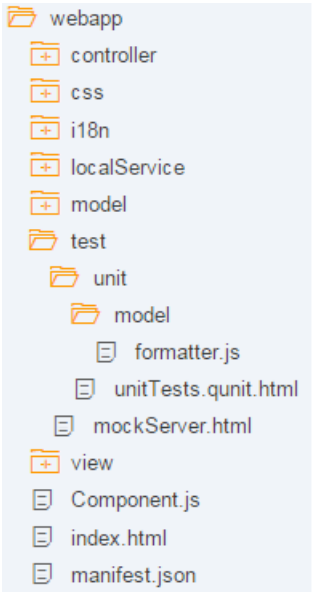

Figure 36: Folder Structure for this Step

We add a new folder `unit` under the `test` folder and a `model` subfolder where we will place our formatter unit test. The folder structure matches the app structure to easily find the corresponding unit tests.

webapp/test/unit/model/formatter.js

```
/*global QUnit*/
```

```
sap.ui.define([
    "sap/ui/demo/walkthrough/model/formatter",
    "sap/ui/model/resource/ResourceModel"
], function (formatter, ResourceModel) {
    "use strict";

    QUnit.module("Formatting functions", {
        beforeEach: function () {
            this._oResourceModel = new ResourceModel({
                bundleUrl: sap.ui.require.toUrl("sap/ui/demo/walkthrough") + "/
i18n/i18n.properties"
            });
        },
        afterEach: function () {
            this._oResourceModel.destroy();
        }
    });

    QUnit.test("Should return the translated texts", function (assert) {

        // Arrange
        // this.stub() does not support chaining and always returns the right
data
        // even if a wrong or empty parameter is passed.
        var oModel = this.stub();
        oModel.withArgs("i18n").returns(this._oResourceModel);
        var oViewStub = {
            getModel: oModel
        };
        var oControllerStub = {
            getView: this.stub().returns(oViewStub)
        };

        // System under test
        var fnIsolatedFormatter = formatter.statusText.bind(oControllerStub);

        // Assert
        assert.strictEqual(fnIsolatedFormatter("A"), "New", "The long text for
status A is correct");

        assert.strictEqual(fnIsolatedFormatter("B"), "In Progress", "The long
text for status B is correct");

        assert.strictEqual(fnIsolatedFormatter("C"), "Done", "The long text for
status C is correct");

        assert.strictEqual(fnIsolatedFormatter("Foo"), "Foo", "The long text for
status Foo is correct");
    });

});
```

We create a new `formatter.js` file under `webapp/test/unit/model` where the unit test for the custom formatter is implemented. The `formatter` file that we want to test is loaded as a dependency. We also need a dependency to the `ResourceModel`, because we want to check if the translated texts are correct.

The formatter file just contains one QUnit module for our formatter function. It instantiates our `ResourceBundle` with the localized texts in the `beforeEach` function and destroys it again in the `afterEach` function. These functions are called before and after each test is executed.

Next is our unit test for the formatter function. In the implementation of the `statusText` function that we created in step 23 we access the `ResourceBundle` with the following queued call: `var resourceBundle = this.getView().getModel("i18n").getResourceBundle();`.

Since we do not want to test the controller, the view, or the model functionality, we first remove the dependencies by replacing these calls with empty hulls with the help of `SinonJS` and its stub method. This happens in the `Arrange` section of the unit test. SinonJS injects a stub method for all objects so we can simply call `this.stub()` to create a new stub for any behavior we need to mock.

Test stubs are functions with pre-programmed behavior. They support the full SinonJS test spy API in addition to methods which can be used to alter the stub's behavior. If this part is a bit confusing have a look at the official SinonJS documentation for test spies or ignore it for now, it will become clear later on.

Then we bind our stub to the `statusText` formatter by calling the `bind` function of JavaScript. The `this` pointer is now bound to our controller stub when the function is invoked using the variable `fnIsolatedFormatter` and we can still pass in arguments as we like. This happens in the "system under test" part of the test.

Finally we perform our assertions. We check each branch of the formatter logic by invoking the isolated formatter function with the values that we expect in the data model (`A`, `B`, `C`, and everything else). We strictly compare the result of the formatter function with the hard-coded strings that we expect from the resource bundle and give a meaningful error message if the test should fail. We hard-code the strings here to identify issues with the resource bundle properties. If a property was missing, the test would still be successful if we check against the real value (that would be an empty string on both sides) from the resource bundle.

webapp/test/unit/unitTests.qunit.html (New)

```
<!DOCTYPE html>

junit.js"></script>
    <script src="https://openui5.hana.ondemand.com/resources/sap/ui/qunit/qunit-
coverage.js"></script>
    <script src="https://openui5.hana.ondemand.com/resources/sap/ui/thirdparty/
sinon.js"></script>
    <script src="https://openui5.hana.ondemand.com/resources/sap/ui/thirdparty/
sinon-qunit.js"></script>

    <script src="unitTests.qunit.js"></script>
</head>
<body>
    <div id="qunit"/>
    <div id="qunit-fixture"/>
```

```
</body>
</html>
```

The so-called QUnit test suite is an HTML page that triggers all QUnit tests for the application. Most of it is generating the layout of the result page that you can see in the preview and we won't further explain these parts but focus on the application parts instead.

Let's start with the namespaces. Since we are now in the `webapp/test/unit` folder, we actually need to go up two levels to get the `src` folder again. This namespace can be used inside the tests to load and trigger application functionality.

First, we load some basic QUnit functionality via script tags. Other QUnit tests can be added here as well. Then the HTML page loads another script called `unitTests.qunit.js`, which we will create next. This script will execute our formatter.

webapp/test/unit/unitTests.qunit.js (New)

```
/* global QUnit */
QUnit.config.autostart = false;
sap.ui.getCore().attachInit(function () {
    "use strict";
    sap.ui.require([
        "sap/ui/demo/walkthrough/test/unit/model/formatter"
    ], function () {
        QUnit.start();
    });
});
```

This script loads and executes our formatter. If we now open the `webapp/test/unit/unitTests.qunit.html` file in the browser, we should see our test running and verifying the formatter logic.

Conventions

- All unit tests are placed in the webapp/test/unit folder of the app.
- Files in the test suite end with `*.qunit.html`.
- The `unitTests.qunit.html` file triggers all unit tests of the app.
- A unit test should be written for formatters, controller logic, and other individual functionality.
- All dependencies are replaced by stubs to test only the functionality in scope.

Testing [page 368]

Step 29: Integration Test with OPA

If we want to test interaction patterns or more visual features of our app, we can also write an integration test.

We haven't thought about testing our interaction with the app yet, so in this step we will check if the dialog actually opens when we click the "Say Hello with Dialog" button. We can easily do this with OPA5, a feature of SAPUI5 that is easy to set up and is based on JavaScript and QUnit. Using integration and unit tests and running them consistently in a continuous integration (CI) environment, we can make sure that we don't accidentally break our app or introduce logical errors in existing code.

> **i Note**
>
> In this tutorial, we focus on a simple use case for the test implementation. If you want to learn more about OPA tests, have a look at our Testing [page 368] tutorial, especially Step 6: A First OPA Test [page 393].

Preview

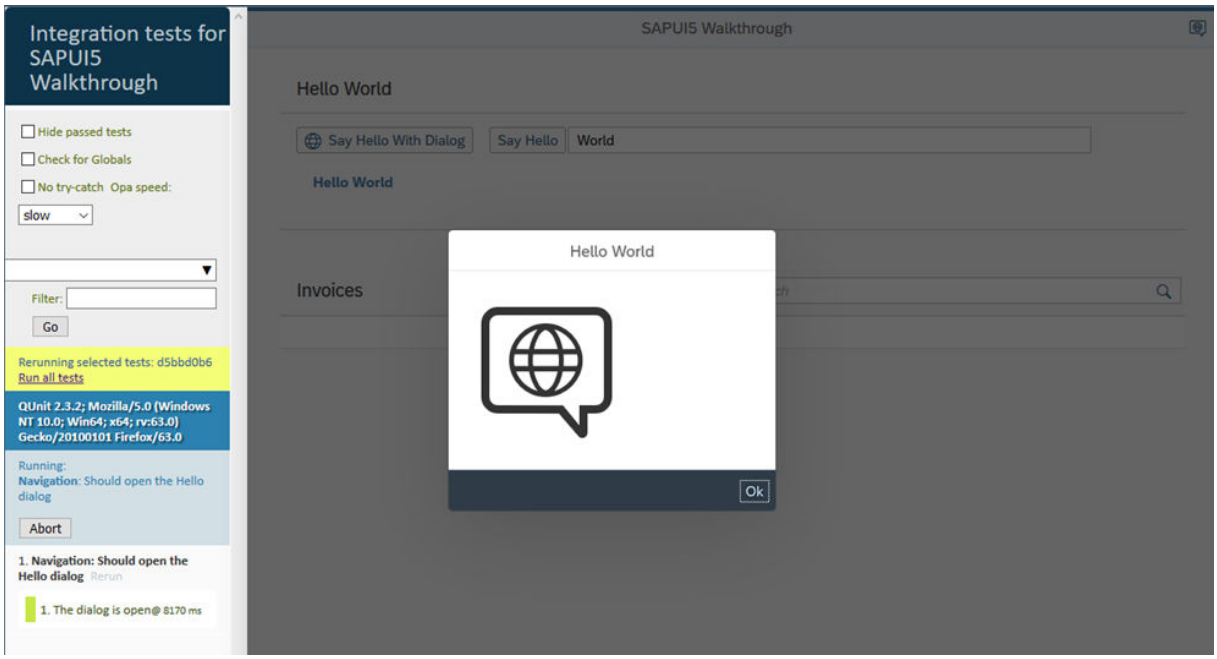

Figure 37: An OPA test opens the "Hello" dialog from step 16

Coding

You can view and download all files at Walkthrough - Step 29.

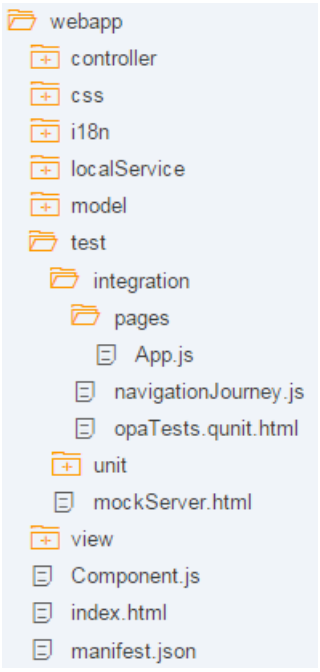

Figure 38: Folder Structure for this Step

We add a new folder `integration` below the `test` folder, where we put our new test cases. Page objects that help structuring such integration tests are put in the `pages` subfolder that we also create now.

webapp/test/integration/NavigationJourney.js (New)

```
/*global QUnit, opaTest*/

sap.ui.define([
    "sap/ui/demo/walkthrough/localService/mockserver",
    "sap/ui/test/opaQunit",
    "./pages/App"
], function (mockserver) {
    "use strict";

    QUnit.module("Navigation");

    opaTest("Should open the Hello dialog", function (Given, When, Then) {
        // initialize the mock server
        mockserver.init();

        // Arrangements
        Given.iStartMyUIComponent({
            componentConfig: {
                name: "sap.ui.demo.walkthrough"
            }
        });

        //Actions
        When.onTheAppPage.iPressTheSayHelloWithDialogButton();

        // Assertions
        Then.onTheAppPage.iShouldSeeTheHelloDialog();
```

```
        // Cleanup
        Then.iTeardownMyApp();
    });
});
```

Let's start with the `journey` first. A `journey` consists of a series of integration tests that belong to the same context such as navigating through the app. Similar to the QUnit test implementation, OPA5 uses QUnit, that's why we first set up a QUnit module `Navigation` that will be displayed on our result page.

The function `opaTest` is the main aspect for defining integration tests with OPA. Its parameters define a test name and a callback function that gets executed with the following OPA5 helper objects to write meaningful tests that read like a user story.

- `Given`
  On the given object we can call arrangement functions like `iStartMyUIComponent` to load our app component for integration testing.
- `When`
  Contains custom actions that we can execute to get the application in a state where we can test the expected behavior.
- `Then`
  Contains custom assertions that check a specific constellation in the application and the teardown function that removes our component again.

In our journey, we create a very simple test that starts the app. Inside the app, we simulate a click on a button and expect that the dialog is opened afterwards. Finally, we shut down the app again.

As you can see, the test case reads like a user story, we actually do not need the implementation of the methods yet to understand the meaning of the test case. This approach is called "Behavior Driven Development" or simply BDD and is popular in "Agile Software Development".

webapp/test/integration/pages/App.js (New)

```
sap.ui.define([
    "sap/ui/test/Opa5",
    "sap/ui/test/actions/Press"
], function (Opa5, Press) {
    "use strict";

    var sViewName = "sap.ui.demo.walkthrough.view.HelloPanel";

    Opa5.createPageObjects({
        onTheAppPage: {
            actions: {
                iPressTheSayHelloWithDialogButton: function () {
                    return this.waitFor({
                        id: "helloDialogButton",
                        viewName: sViewName,
                        actions: new Press(),
                        errorMessage: "Did not find the 'Say Hello With Dialog'
button on the HelloPanel view"
                    });
                }
            },

            assertions: {
                iShouldSeeTheHelloDialog: function () {
```

```
                    return this.waitFor({
                        controlType: "sap.m.Dialog",
                        success: function () {
                            // we set the view busy, so we need to query the
parent of the app
                            Opa5.assert.ok(true, "The dialog is open");
                        },
                        errorMessage: "Did not find the dialog control"
                    });
                }
            }
        }
    });
});
```

The implementation of the page object holds the helper functions we just called in our `journey`. We require OPA5 from the `sap.ui.test` namespace and define a page object with the helper function `createPageObjects`. We pass in an object with the key of our page `onTheAppPage` and two sections: `actions` and `assertions`.

In the actions section of the page object we define a function to click the "Hello" dialog button. This is done in OPA5 with a `waitFor` statement, it is basically a loop that checks for the conditions defined as parameters. If the conditions are met, the success callback is executed, if the test fails because the conditions have not been met, the text in the `errorMessage` property is displayed on the result page.

We define a `waitFor` statement that checks for controls of type `sap.m.Button`. As soon as a button is found on the app page the success handler is executed and we use jQuery to trigger a `tap` event on the first button that we found. This should open the `HelloDialog` similar to clicking on the button manually.

In the assertions section we define another `waitFor` statement that checks if a `sap.m.Dialog` control is existing in the DOM of the app. When the dialog has been found, the test is successful and we can immediately confirm by calling an `ok` statement with a meaningful message.

webapp/test/integration/opaTests.qunit.html (New)

```
<!DOCTYPE html>
<html>
<head>
    <title>Integration tests for SAPUI5 Walkthrough</title>
    <meta charset="utf-8">

    <script
        id="sap-ui-bootstrap"
        src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.walkthrough": "../../"
        }'
        data-sap-ui-animation="false"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true">
    </script>

    <link rel="stylesheet" type="text/css" href="https://
openui5.hana.ondemand.com/resources/sap/ui/thirdparty/qunit-2.css">

    <script src="https://openui5.hana.ondemand.com/resources/sap/ui/thirdparty/
qunit-2.js"></script>
```

```
    <script src="https://openui5.hana.ondemand.com/resources/sap/ui/qunit/qunit-
junit.js"></script>

    <script src="opaTests.qunit.js"></script>
</head>
<body>
    <div id="qunit"></div>
    <div id="qunit-fixture"></div>
</body>
</html>
```

This file contains our test suite for all OPA tests of the app. We use the same namespace as for our application.

Then we load the basic QUnit functionality via script tags from SAPUI5 so that we can execute the test journey. The `NavigationJourney` we defined above will be loaded via a script called `opaTests.qunit.js`:

webapp/test/integration/opaTests.qunit.js (New)

```
/* global QUnit */
QUnit.config.autostart = false;
sap.ui.getCore().attachInit(function () {
    "use strict";
    sap.ui.require([
        "sap/ui/demo/walkthrough/test/integration/NavigationJourney"
    ], function () {
        QUnit.start();
    });
});
```

This script loads the `NavigationJourney`, and the test functions inside are immediately executed. When you call the `webapp/test/integration/opaTests.qunit.html` page of your project on the server, you should see the QUnit layout and a test “Should see the Hello dialog” is executed immediately. It will load the app component on the right side of the page. There you can see what operations the test is performing on the app, if everything works correctly the button click is triggered, then a dialog is shown and the test case is green.

Conventions

- OPA tests are located in the `webapp/test/integration` folder of the application.
- Use `page` objects and `journeys` for structuring OPA tests.

Step 30: Debugging Tools

Even though we have added a basic test coverage in the previous steps, it seems like we accidentally broke our app, because it does not display prices to our invoices anymore. We need to debug the issue and fix it before someone finds out.

Luckily, SAPUI5 provides a couple of debugging tools that we can use within the app to check the application logic and the developer tools of modern browsers are also quite good. We will now check for the root cause.

Preview

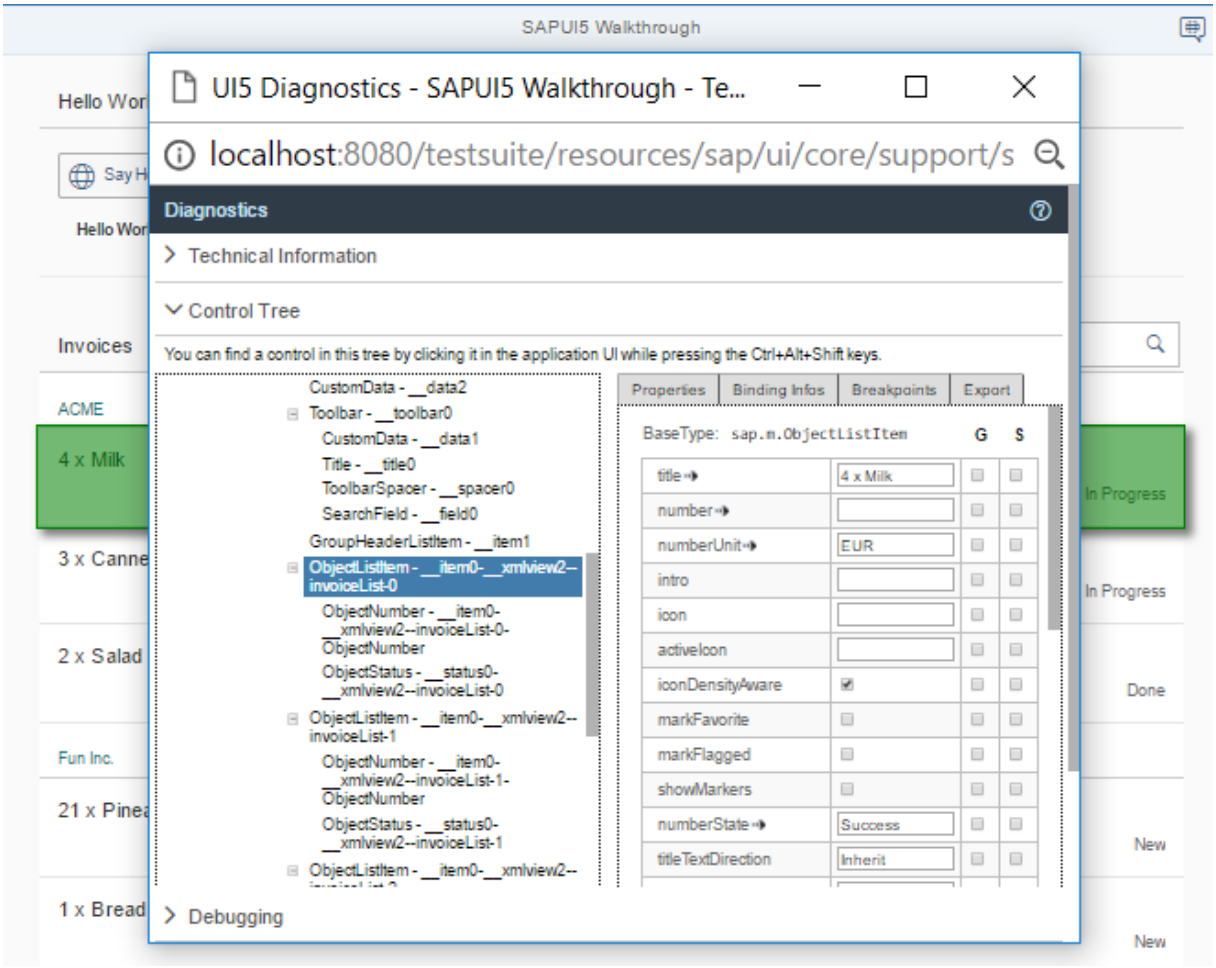

Figure 39: The diagnostics window

Coding

You can view and download all files at Walkthrough - Step 30.

webapp/view/InvoiceList.view.xml

```
<mvc:View
        controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
        xmlns="sap.m"
        xmlns:mvc="sap.ui.core.mvc">
    <List
            id="invoiceList"
            class="sapUiResponsiveMargin"
            width="auto"
            items="{
            path : 'invoice>/Invoices',
            sorter : {
                path : 'ShipperName',
                group : true
            }
        }">
        <headerToolbar>
            <Toolbar>
                <Title text="{i18n>invoiceListTitle}"/>
                <ToolbarSpacer/>
                <SearchField width="50%" search=".onFilterInvoices"/>
            </Toolbar>
        </headerToolbar>
        <items>
            <ObjectListItem
                    title="{invoice>Quantity} x {invoice>ProductName}"
                    number="{
                    parts: [{path: 'invoice>ExTendedPrice'}, {path: 'view>/
currency'}],
                    type: 'sap.ui.model.type.Currency',
                    formatOptions: {
                        showMeasure: false
                    }
                }"
                numberUnit="{view>/currency}"
                    numberState="{=    ${invoice>ExtendedPrice} > 50 ? 'Error' :
'Success' }">
                <attributes>
                    <ObjectAttribute text="{
                        path: 'invoice>Status',
                        formatter: '.formatter.statusText'
                    }"/>
                </attributes>
            </ObjectListItem>
        </items>
    </List>
</mvc:View>
```

We introduced a typo in the binding of the number attribute to simulate a frequent error; instead of using `'invoice>ExtendedPrice'` we use `'invoice>ExTendedPrice'`. Now we call the app and notice that the price is actually missing. By pressing CTRL + ALT + SHIFT + S we open the SAPUI5 support diagnostics tool and check the app.

> **i Note**
>
> If you use the Google Chrome browser, you can install the *UI5 Inspector* plugin. With this plugin, you can easily debug your SAPUI5- or OpenUI5-based apps. For more information, see UI5 Inspector [page 1374].

Besides technical information about the app and a trace that is similar to the developer tools console of the browser, there is a really handy tool for checking such errors in this dialog. Open the tab *Control Tree* by clicking on the expand symbol on the right.

A hierarchical tree of SAPUI5 controls is shown on the left and the properties of the selected control are displayed on the right. If we now select the first `ObjectListItem` control of the tree and go to the *Binding Infos* tab on the right, we can actually see that the binding path of the number attribute is marked as invalid. We can now correct the error in the view and the price should appear in the list of invoices again.

Sometimes errors are not as easy to spot and you actually need to debug the JavaScript code with the tools of the browser. For performance reasons, the SAPUI5 files are shipped in a minified version, this means that all possible variable names are shortened and comments are removed.

This makes debugging harder because the code is a lot less readable. You can load the debug sources by adding the URL parameter `sap-ui-debug=true` or by pressing `CTRL` + `ALT` + `SHIFT` + `P` and select *Use Debug Sources* in the dialog box that is displayed. After reloading the page, you can see in the *Network* tab of the browser's developer tools that now a lot of files with the `-dbg` suffix are loaded. These are the source code files that include comments and the uncompressed code of the app and the SAPUI5 artifacts.

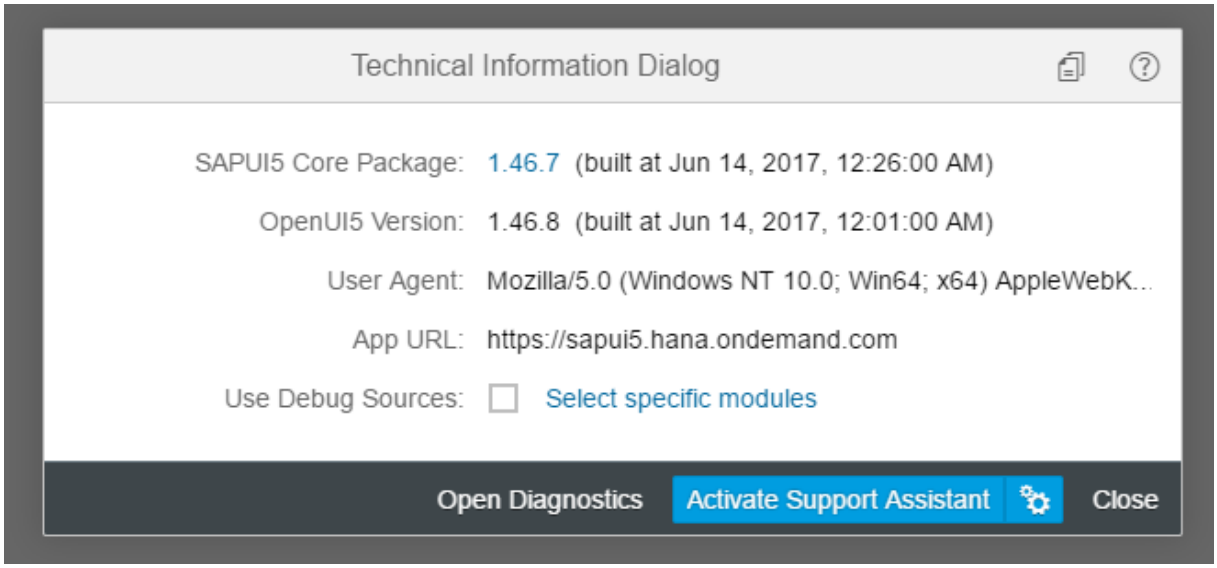

Figure 40: Technical information dialog

For a more detailed explanation of the SAPUI5 support tools, go through the Troubleshooting [page 194] tutorial.

If you're stuck and need help for some development task, you can also post a question in the SAPUI5-related forums, for example in the SAP Community or on Stack Overflow.

Conventions

- As per SAPUI5 convention uncompressed source files end with `*-dbg.js`

Debugging [page 1315]
Diagnostics [page 1326]

Technical Information Dialog [page 1322]

Step 31: Routing and Navigation

So far, we have put all app content on one single page. As we add more and more features, we want to split the content and put it on separate pages.

In this step, we will use the SAPUI5 navigation features to load and show a separate detail page that we can later use to display details for an invoice. In the previous steps, we defined the page directly in the app view so that it is displayed when the app is loaded. We will now use the SAPUI5 router class to load the pages and update the URL for us automatically. We specify a routing configuration for our app and create a separate view for each page of the app, then we connect the views by triggering navigation events.

Preview

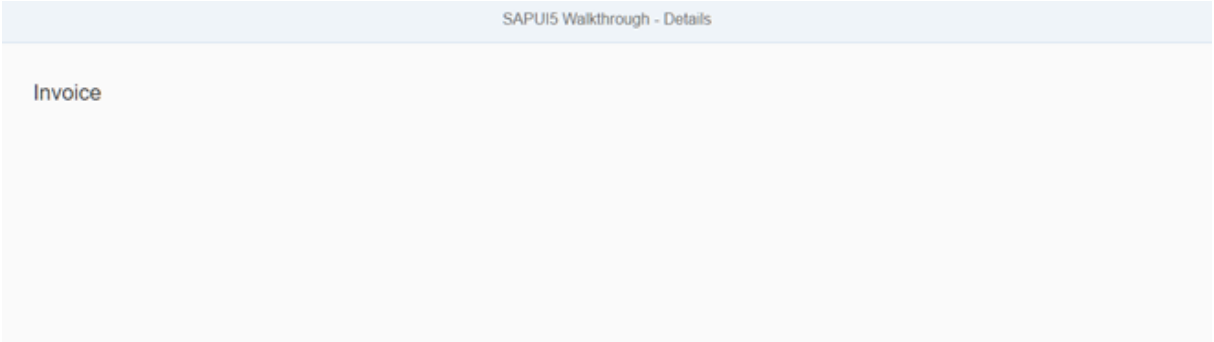

Figure 41: A second page is added to display the invoice

Coding

You can view and download all files at Walkthrough - Step 31.

webapp/manifest.json

```
{
  "_version": "1.12.0",
  …
  "sap.ui5": {
    …
    "models": {
        …
    },
    "routing": {
      "config": {
        "routerClass": "sap.m.routing.Router",
        "viewType": "XML",
```

```
        "viewPath": "sap.ui.demo.walkthrough.view",
        "controlId": "app",
        "controlAggregation": "pages",
        "async": true
      },
      "routes": [
        {
          "pattern": "",
          "name": "overview",
          "target": "overview"
        },
        {
          "pattern": "detail",
          "name": "detail",
          "target": "detail"
        }
      ],
      "targets": {
        "overview": {
          "viewId": "overview",
          "viewName": "Overview"
        },
        "detail": {
          "viewId": "detail",
          "viewName": "Detail"
        }
      }
    }
  }
```

We add a new “routing" section to the `sap.ui5` part of the descriptor. There are three subsections that define the routing and navigation structure of the app:

- `config`
  This section contains the global router configuration and default values that apply for all routes and targets. We define the router class that we want to use and where our views are located in the app. To load and display views automatically, we also specify which control is used to display the pages and what aggregation should be filled when a new page is displayed.
- `routes`
  Each route defines a name, a pattern, and one or more targets to navigate to when the route has been hit. The pattern is basically the URL part that matches to the route, we define two routes for our app. The first one is a default route that will show the overview page with the content from the previous steps, and the second is the detail route with the URL pattern `detail` that will show a new page.
- `targets`
  A target defines a view that is displayed, it is associated with one or more routes and it can also be displayed manually from within the app. Whenever a target is displayed, the corresponding view is loaded and shown in the app. In our app we simply define two targets with a view name that corresponds to the target name.

webapp/Component.js

```
sap.ui.define([
    "sap/ui/core/UIComponent",
    "sap/ui/model/json/JSONModel",
    "./controller/HelloDialog"
], function (UIComponent, JSONModel, HelloDialog) {
```

```
    "use strict";
    return UIComponent.extend("sap.ui.demo.walkthrough.Component", {
        metadata: {
            manifest: "json"
        },
        init: function () {
            // call the init function of the parent
            UIComponent.prototype.init.apply(this, arguments);
            // set data model
            var oData = {
                recipient: {
                    name: "World"
                }
            };
            var oModel = new JSONModel(oData);
            this.setModel(oModel);
            // set dialog
            this._helloDialog = new HelloDialog(this.getRootControl());
            // create the views based on the url/hash
            this.getRouter().initialize();
        },
    });
        exit : function () {
            this._helloDialog.destroy();
            delete this._helloDialog;
        },
        openHelloDialog : function () {
            this._helloDialog.open();
        }
    });
});
```

In the component initialization method, we now add a call to initialize the router. We do not need to instantiate the router manually, it is automatically instantiated based on our `AppDescriptor` configuration and assigned to the component.

Initializing the router will evaluate the current URL and load the corresponding view automatically. This is done with the help of the routes and targets that have been configured in the `AppDescriptor`. If a route has been hit, the view of its corresponding target is loaded and displayed.

webapp/view/Overview.view.xml (New)

```
<mvc:View
        controllerName="sap.ui.demo.walkthrough.controller.App"
        xmlns="sap.m"
        xmlns:mvc="sap.ui.core.mvc">
    <Page title="{i18n>homePageTitle}">
        <headerContent>
            <Button
                    icon="sap-icon://hello-world"
                    press=".onOpenDialog"/>
        </headerContent>
        <content>
            <mvc:XMLView viewName="sap.ui.demo.walkthrough.view.HelloPanel"/>
            <mvc:XMLView viewName="sap.ui.demo.walkthrough.view.InvoiceList"/>
        </content>
    </Page>
</mvc:View>
```

We move the content of the previous steps from the `App` view to a new `Overview` view. For simplicity, we do not change the controller as it only contains our helper method to open the dialog, that means we reuse the

controller `sap.ui.demo.walkthrough.controller.App` for two different views (for the new overview and for the app view). However, two instances of that controller are instantiated at runtime. In general, one instance of a controller is instantiated for each view that references the controller.

webapp/view/App.view.xml

```
<mvc:View
        controllerName="sap.ui.demo.walkthrough.controller.App"
        xmlns="sap.m"
        xmlns:mvc="sap.ui.core.mvc"
        displayBlock="true">
<Shell>
    <App class="myAppDemoWT" id="app"/>
</Shell>
</mvc:View>
```

Our `App` view is now only containing the empty app tag. The router will automatically add the view that corresponds to the current URL into the app control. The router identifies the app control with the ID that corresponds to the property `controlId: "app"` in the `AppDescriptor`.

webapp/view/Detail.view.xml (New)

```
<mvc:View
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page
        title="{i18n>detailPageTitle}">
        <ObjectHeader
            title="Invoice"/>
    </Page>
</mvc:View>
```

Now we add a second view for the detail view. It only contains a page and an `ObjectHeader` control that displays the static text *Invoice* for now.

webapp/i18n/i18n.properties

```
…
# Invoice List
invoiceListTitle=Invoices
invoiceStatusA=New
invoiceStatusB=In Progress
invoiceStatusC=Done
# Detail Page
detailPageTitle=Walkthrough - Details
```

We add a new string to the resource bundle for the detail page title.

webapp/view/InvoiceList.view.xml

```
<mvc:View
        controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
        xmlns="sap.m"
        xmlns:mvc="sap.ui.core.mvc">
    <List    …>
        …
        <items>
            <ObjectListItem

                    title="{invoice>Quantity} x {invoice>ProductName}"
                    number="{
                    parts: [{path: 'invoice>ExtendedPrice'}, {path: 'view>/
currency'}],
                    type: 'sap.ui.model.type.Currency',
                    formatOptions: {
                        showMeasure: false
                    }
                }"
                    numberUnit="{view>/currency}"
                    numberState="{=    ${invoice>ExtendedPrice} > 50 ? 'Error' :
'Success' }"
                    type="Navigation"
                    press="onPress">
                <firstStatus>
                    <ObjectStatus text="{
                        path: 'invoice>Status',
                        formatter: '.formatter.statusText'
                    }"/>
                </firstStatus>
            </ObjectListItem>
        </items>
    </List>
</mvc:View>
```

In the invoice list view we add a press event to the list item and set the item type to `Navigation` so that the item can actually be clicked.

webapp/controller/InvoiceList.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "../model/formatter",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator"
], function (Controller, JSONModel, formatter, Filter, FilterOperator) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.InvoiceList", {
        …
        onPress: function (oEvent) {
            var oRouter = sap.ui.core.UIComponent.getRouterFor(this);
            oRouter.navTo("detail");
        }
    });
});
```

We add the event handler function to the controller of our invoices list. Now it is time to navigate to the detail page by clicking an item in the invoice list. We access the router instance for our app by calling the helper

method `sap.ui.core.UIComponent.getRouterFor(this)`. On the router we call the `navTo` method to navigate to the `detail` route that we specified in the routing configuration.

You should now see the detail page when you click an item in the list of invoices.

Conventions

- Define the routing configuration in the descriptor

Samples: `sap.m.routing.Router`

Step 32: Routing with Parameters

We can now navigate between the overview and the detail page, but the actual item that we selected in the overview is not displayed on the detail page yet. A typical use case for our app is to show additional information for the selected item on the detail page.

To make this work, we have to pass over the information which item has been selected to the detail page and show the details for the item there.

Preview

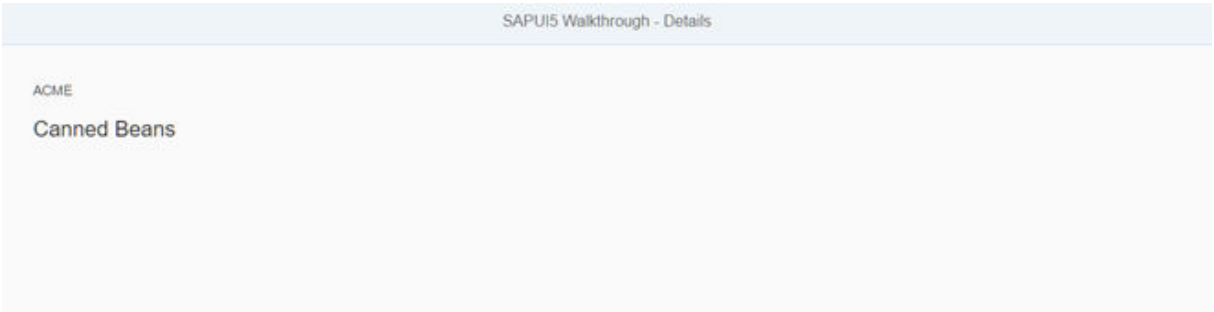

Figure 42: The selected invoice details are now shown in the details page

Coding

You can view and download all files at Walkthrough - Step 32.

webapp/manifest.json

```
{
  "_version": "1.12.0",
  …
  "sap.ui5": {
    …
    "routing": {
      "config": {
        "routerClass": "sap.m.routing.Router",
        "viewType": "XML",
        "viewPath": "sap.ui.demo.walkthrough.view",
        "controlId": "app",
        "controlAggregation": "pages",
        "async": true
      },
      "routes": [
        {
          "pattern": "",
          "name": "overview",
          "target": "overview"
        },
        {
          "pattern": "detail/{invoicePath}",
          "name": "detail",
          "target": "detail"
        }
      ],
          "targets": {
        "overview": {
          "viewID": "overview"
          "viewName": "Overview"
        },
        "detail": {
          "viewId": "detail"
          "viewName": "Detail"
        }
      }
    }
  }
}
```

We now add a navigation parameter `invoicePath` to the detail route so that we can hand over the information for the selected item to the detail page. Mandatory navigation parameters are defined with curly brackets.

webapp/view/Detail.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.Detail"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
```

```
    <Page
        title="{i18n>detailPageTitle}">
        <ObjectHeader
            intro="{invoice>ShipperName}"
            title="{invoice>ProductName}"/>
    </Page>
</mvc:View>
```

We add a controller that will take care of setting the item's context on the view and bind some properties of the `ObjectHeader` to the fields of our `invoice` model. We could add more detailed information from the `invoice` object here, but for simplicity reasons we just display two fields for now.

webapp/controller/InvoiceList.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "../model/formatter",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator"
], function (Controller, JSONModel, formatter, Filter, FilterOperator) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.InvoiceList", {
        …
        onPress: function (oEvent) {
            var oItem = oEvent.getSource();
            var oRouter = sap.ui.core.UIComponent.getRouterFor(this);
            oRouter.navTo("detail", {
                invoicePath:
window.encodeURIComponent(oItem.getBindingContext("invoice").getPath().substr(1))
            });
        }
    });
});
```

The control instance that has been interacted with can be accessed by the `getSource` method that is available for all SAPUI5 events. It will return the `ObjectListItem` that has been clicked in our case. We will use it to pass the information of the clicked item to the detail page so that the same item can be displayed there.

In the `navTo` method we now add a configuration object to fill the navigation parameter `invoicePath` with the current information of the item. This will update the URL and navigate to the detail view at the same time. On the detail page, we can access this `context` information again and display the corresponding item.

To identify the object that we selected, we would typically use the key of the item in the back-end system because it is short and precise. For our invoice items however, we do not have a simple key and directly use the binding path to keep the example short and simple. The path to the item is part of the binding context which is a helper object of SAPUI5 to manage the binding information for controls. The binding context can be accessed by calling the `getBindingContext` method with the model name on any bound SAPUI5 control. We need to remove the first `/` from the binding path by calling `.substr(1)` on the string because this is a special character in URLs and is not allowed, we will add it again on the detail page.

webapp/controller/Detail.controller.js (New)

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/core/UIComponent"
], function (Controller, UIComponent) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.Detail", {
        onInit: function () {
            var oRouter = sap.ui.core.UIComponent.getRouterFor(this);

oRouter.getRoute("detail").attachPatternMatched(this._onObjectMatched, this);
        },
        _onObjectMatched: function (oEvent) {
            this.getView().bindElement({
                path: "/" +
window.decodeURIComponent(oEvent.getParameter("arguments").invoicePath),
                model: "invoice"
            });
        }
    });
});
```

Our last piece to fit the puzzle together is the detail controller. It needs to set the context that we passed in with the URL parameter `invoicePath` on the view, so that the item that has been selected in the list of invoices is actually displayed, otherwise, the view would simply stay empty.

In the `onInit` method of the controller we fetch the instance of our app router and attach to the detail route by calling the method `attachPatternMatched` on the route that we accessed by its name. We register an internal callback function `_onObjectMatched` that will be executed when the route is hit, either by clicking on the item or by calling the app with a URL for the detail page.

In the `_onObjectMatched` method that is triggered by the router we receive an event that we can use to access the URL and navigation parameters. The `arguments` parameter will return an object that corresponds to our navigation parameters from the route pattern. We access the `invoicePath` that we set in the invoice list controller and call the `bindElement` function on the view to set the context. We have to add the root `/` in front of the path again that was removed for passing on the path as a URL parameter.

The `bindElement` function is creating a binding context for a SAPUI5 control and receives the model name as well as the path to an item in a configuration object. This will trigger an update of the UI controls that we connected with fields of the invoice model. You should now see the invoice details on a separate page when you click on an item in the list of invoices.

Conventions

- Define the routing configuration in the `AppDescriptor`

Routing and Navigation [page 1072]

Tutorial: Navigation and Routing [page 291]
API Reference: `sap.m.routing.Router`
Samples: `sap.m.routing.Router`

Step 33: Routing Back and History

Now we can navigate to our detail page and display an invoice, but we cannot go back to the overview page yet. We'll add a back button to the detail page and implement a function that shows our overview page again.

Preview

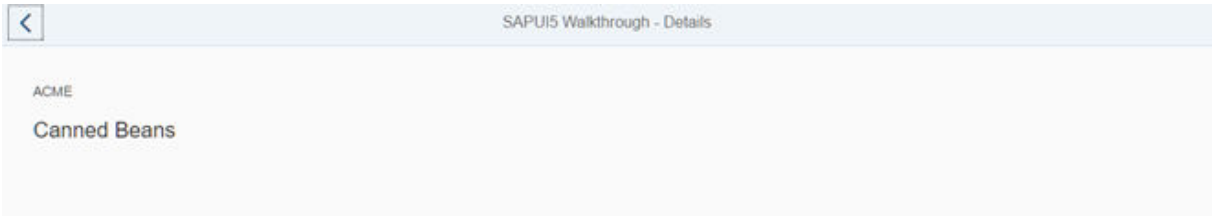

Figure 43: A back button is now displayed on the detail page

Coding

You can view and download all files at Walkthrough - Step 33.

webapp/view/Detail.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.Detail"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page
        title="{i18n>detailPageTitle}"
        showNavButton="true"
        navButtonPress=".onNavBack">
        <ObjectHeader
            intro="{invoice>ShipperName}"
            title="{invoice>ProductName}"/>
    </Page>
</mvc:View>
```

On the detail page, we tell the control to display a back button by setting the parameter `showNavButton` to true and register an event handler that is called when the back button is pressed.

webapp/controller/Detail.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/core/routing/History",
    "sap/ui/core/UIComponent"
], function (Controller, History, UIComponent) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.Detail", {
        onInit: function () {
            var oRouter = UIComponent.getRouterFor(this);

oRouter.getRoute("detail").attachPatternMatched(this._onObjectMatched, this);
        },
        _onObjectMatched: function (oEvent) {
            this.getView().bindElement({
                path: "/" +
window.decodeURIComponent(oEvent.getParameter("arguments").invoicePath),
                model: "invoice"
            });
        },

        onNavBack: function () {
            var oHistory = History.getInstance();
            var sPreviousHash = oHistory.getPreviousHash();

            if (sPreviousHash !== undefined) {
                window.history.go(-1);
            } else {
                var oRouter = UIComponent.getRouterFor(this);
                oRouter.navTo("overview", {}, true);
            }
        }
    });
});
```

We load a new dependency that helps us to manage the navigation history from the `sap.ui.core.routing` namespace and add the implementation for the event handler to our detail page controller.

In the event handler we access the navigation history and try to determine the previous hash. In contrast to the browser history, we will get a valid result only if a navigation step inside our app has already happened. Then we will simply use the browser history to go back to the previous page. If no navigation has happened before, we can tell the router to go to our overview page directly. The third parameter `true` tells the router to replace the current history state with the new one since we actually do a back navigation by ourselves. The second parameter is an empty array (`{}`) as we do not pass any additional parameters to this route.

This implementation is a bit better than the browser's back button for our use case. The browser would simply go back one step in the history even though we were on another page outside of the app. In the app, we always want to go back to the overview page even if we came from another link or opened the detail page directly with a bookmark. You can try it by loading the detail page in a new tab directly and clicking on the back button in the app, it will still go back to the overview page.

Conventions

- Add a path to go back to the parent page when the history state is unclear.

Step 34: Custom Controls

In this step, we are going to extend the functionality of SAPUI5 with a custom control. We want to rate the product shown on the detail page, so we create a composition of multiple standard controls using the SAPUI5 extension mechanism and add some glue code to make them work nicely together. This way, we can reuse the control across the app and keep all related functionality in one module.

Preview

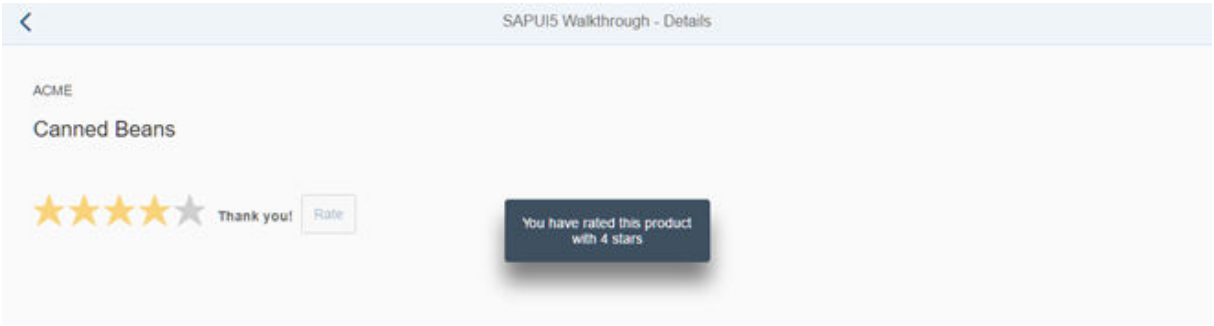

Figure 44: A custom product rating control is added to the detail page

Coding

You can view and download all files at Walkthrough - Step 34.

webapp/control/ProductRating.js (New)

```
sap.ui.define([
    "sap/ui/core/Control"
], function (Control) {
    "use strict";
    return Control.extend("sap.ui.demo.walkthrough.control.ProductRating", {
        metadata : {
        },
        init : function () {
        },
        renderer : function (oRM, oControl) {
        }
    });
});
```

We create a new folder `control` and a file `ProductRating.js` that will hold our new control. As with our controllers and views, the custom control inherits the common control functionality from a SAPUI5 base object, for controls this is done by extending the base class `sap.ui.core.Control`.

Custom controls are small reuse components that can be created within the app very easily. Due to their nature, they are sometimes also referred to as "notepad" or "on the fly" controls. A custom control is a

JavaScript object that has two special sections (`metadata` and `renderer`) and a number of methods that implement the functionality of the control.

The `metadata` section defines the data structure and thus the API of the control. With this meta information on the properties, events, and aggregations of the control SAPUI5 automatically creates setter and getter methods and other convenience functions that can be called within the app.

The renderer defines the HTML structure that will be added to the DOM tree of your app whenever the control is instantiated in a view. It is usually called initially by the core of SAPUI5 and whenever a property of the control is changed. The parameter `oRM` of the render function is the SAPUI5 render manager that can be used to write strings and control properties to the HTML page.

The `init` method is a special function that is called by the SAPUI5 core whenever the control is instantiated. It can be used to set up the control and prepare its content for display.

> **i** Note
>
> Controls always extend `sap.ui.core.Control` and render themselves. You could also extend `sap.ui.core.Element` or `sap.ui.base.ManagedObject` directly if you want to reuse life cycle features of SAPUI5 including data binding for objects that are not rendered. Please refer to the API reference to learn more about the inheritance hierarchy of controls.

webapp/control/ProductRating.js

```
sap.ui.define([
    "sap/ui/core/Control",
    "sap/m/RatingIndicator",
    "sap/m/Label",
    "sap/m/Button"
], function (Control, RatingIndicator, Label, Button) {
    "use strict";
    return Control.extend("sap.ui.demo.walkthrough.control.ProductRating", {
        metadata : {
            properties : {
                value:     {type : "float", defaultValue : 0}
            },
            aggregations : {
                _rating : {type : "sap.m.RatingIndicator", multiple: false,
visibility : "hidden"},
                _label : {type : "sap.m.Label", multiple: false, visibility :
"hidden"},
                _button : {type : "sap.m.Button", multiple: false, visibility :
"hidden"}
            },
            events : {
                change : {
                    parameters : {
                        value : {type : "int"}
                    }
                }
            }
        },
        init : function () {
            this.setAggregation("_rating", new RatingIndicator({
                value: this.getValue(),
                iconSize: "2rem",
                visualMode: "Half",
                liveChange: this._onRate.bind(this)
```

```
            }));
            this.setAggregation("_label", new Label({
                text: "{i18n>productRatingLabelInitial}"
            }).addStyleClass("sapUiSmallMargin"));
            this.setAggregation("_button", new Button({
                text: "{i18n>productRatingButton}",
                press: this._onSubmit.bind(this)
            }).addStyleClass("sapUiTinyMarginTopBottom"));
        },

        setValue: function (fValue) {
            this.setProperty("value", fValue, true);
            this.getAggregation("_rating").setValue(fValue);
        },

        reset: function () {
            var oResourceBundle = this.getModel("i18n").getResourceBundle();

            this.setValue(0);
            this.getAggregation("_label").setDesign("Standard");
            this.getAggregation("_rating").setEnabled(true);

this.getAggregation("_label").setText(oResourceBundle.getText("productRatingLabel
Initial"));
            this.getAggregation("_button").setEnabled(true);
        },

        _onRate : function (oEvent) {
            var oRessourceBundle = this.getModel("i18n").getResourceBundle();
            var fValue = oEvent.getParameter("value");

            this.setProperty("value", fValue, true);

this.getAggregation("_label").setText(oRessourceBundle.getText("productRatingLabe
lIndicator", [fValue, oEvent.getSource().getMaxValue()]));
            this.getAggregation("_label").setDesign("Bold");
        },

        _onSubmit : function (oEvent) {
            var oResourceBundle = this.getModel("i18n").getResourceBundle();

            this.getAggregation("_rating").setEnabled(false);

this.getAggregation("_label").setText(oResourceBundle.getText("productRatingLabel
Final"));
            this.getAggregation("_button").setEnabled(false);
            this.fireEvent("change", {
                value: this.getValue()
            });
        },
        renderer : function (oRm, oControl) {
            oRm.openStart("div", oControl);
            oRm.class("myAppDemoWTProductRating");
            oRm.openEnd();
            oRm.renderControl(oControl.getAggregation("_rating"));
            oRm.renderControl(oControl.getAggregation("_label"));
            oRm.renderControl(oControl.getAggregation("_button"));
            oRm.close("div");
        }
    });
});
```

We now enhance our new custom control with the custom functionality that we need. In our case we want to create an interactive product rating, so we define a value and use three internal controls that are displayed

updated by our control automatically. A `RatingIndicator` control is used to collect user input on the product, a label is displaying further information, and a button submits the rating to the app to store it.

In the `metadata` section we therefore define several properties that we make use in the implementation:

- Properties
  - Value
    We define a control property `value` that will hold the value that the user selected in the rating. Getter and setter function for this property will automatically be created and we can also bind it to a field of the data model in the XML view if we like.
- Aggregations
  As described in the first paragraph, we need three internal controls to realize our rating functionality. We therefore create three "hidden aggregations" by setting the `visibility` attribute to `hidden`. This way, we can use the models that are set on the view also in the inner controls and SAPUI5 will take care of the lifecycle management and destroy the controls when they are not needed anymore. Aggregations can also be used to hold arrays of controls but we just want a single control in each of the aggregations so we need to adjust the cardinality by setting the attribute `multiple` to `false`.
  - `_rating`: A `sap.m.RatingIndicator` control for user input
  - `_label`: A `sap.m.Label` to display additional information
  - `_button`: A `sap.m.Button` to submit the rating

  > **i** Note
  >
  > You can define `aggregations` and `associations` for controls. The difference is in the relation between the parent and the related control:
  > - An **aggregation** is a strong relation that also manages the lifecycle of the related control, for example, when the parent is destroyed, the related control is also destroyed. Also, a control can only be assigned to one single aggregation, if it is assigned to a second aggregation, it is removed from the previous aggregation automatically.
  > - An **association** is a weak relation that does not manage the lifecycle and can be defined multiple times. To have a clear distinction, an association only stores the ID, whereas an aggregation stores the direct reference to the control. We do not specify associations in this example, as we want to have our internal controls managed by the parent.
- Events
  - Change
    We specify a `change` event that the control will fire when the rating is submitted. It contains the current value as an event parameter. Applications can register to this event and process the result similar to "regular" SAPUI5 controls, which are in fact built similar to custom controls.

In the `init` function that is called by SAPUI5 automatically whenever a new instance of the control is instantiated, we set up our internal controls. We instantiate the three controls and store them in the internal aggregation by calling the framework method `setAggregation` that has been inherited from `sap.ui.core.Control`. We pass on the name of the internal aggregations that we specified above and the new control instances. We specify some control properties to make our custom control look nicer and register a `liveChange` event to the rating and a press event to the button. The initial texts for the label and the button are referenced from our `i18n` model.

Let's ignore the other internal helper functions and event handlers for now and define our renderer. With the help of the SAPUI5 render manager and the control instance that are passed on as a reference, we can now render the HTML structure of our control. We render the start of the outer `<div>` tag as `<div` and call the

helper method `writeControlData` to render the ID and other basic attributes of the control inside the `div` tag. Next, we add a custom CSS class so that we can define styling rules for the custom control in our CSS file later. This CSS class and others that have been added in the view are then rendered by calling `writeClasses` on the renderer instance. Then we close the surrounding `div` tag and render three internal controls by passing the content of the internal aggregation to the render managers `renderControl` function. This will call the renderer of the controls and add their HTML to the page. Finally, we close our surrounding `<div>` tag.

The `setValue` is an overridden setter. SAPUI5 will generate a setter that updates the property value when called in a controller or defined in the XML view, but we also need to update the internal rating control in the hidden aggregation to reflect the state properly. Also, we can skip the rerendering of SAPUI5 that is usually triggered when a property is changed on a control by calling the `setProperty` method to update the control property with true as the third parameter.

Now we define the event handler for the internal rating control. It is called every time the user changes the rating. The current value of the rating control can be read from the event parameter value of the `sap.m.RatingIndicator` control. With the value we call our overridden setter to update the control state, then we update the `label` next to the rating to show the user which value he has selected currently and also displays the maximum value. The string with the placeholder values is read from the `i18n` model that is assigned to the control automatically.

Next, we have the `press` handler for the rating button that submits our rating. We assume that rating a product is a one-time action and first disable the rating and the button so that the user is not allowed to submit another rating. We also update the label to show a "Thank you for your rating!" message, then we fire the change event of the control and pass in the current value as a parameter so that applications that are listening to this event can react on the rating interaction.

We define the `reset` method to be able to revert the state of the control on the UI to its initial state so that the user can again submit a rating.

webapp/view/Detail.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.Detail"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:wt="sap.ui.demo.walkthrough.control">
    <Page
        title="{i18n>detailPageTitle}"
        showNavButton="true"
        navButtonPress=".onNavBack">
        <ObjectHeader
            intro="{invoice>ShipperName}"
            title="{invoice>ProductName}"/>
        <wt:ProductRating id="rating" class="sapUiSmallMarginBeginEnd"
change=".onRatingChange"/>
    </Page>
</mvc:View>
```

A new namespace `wt` is defined on the detail view so that we can reference our custom controls easily in the view. We then add an instance of the `ProductRating` control to our detail page and register an event handler for the change event. To have a proper layout, we also add a margin style class.

webapp/controller/Detail.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/core/routing/History",
    "sap/m/MessageToast",
    "sap/ui/core/UIComponent"
], function (Controller, History, MessageToast, UIComponent) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.Detail", {
        …
        _onObjectMatched: function (oEvent) {
            this.byId("rating").reset();
            this.getView().bindElement({
                path: "/" +
window.decodeURIComponent(oEvent.getParameter("arguments").invoicePath),
                model: "invoice"
            });
        },
        onNavBack: function () {
            var oHistory = History.getInstance();
            var sPreviousHash = oHistory.getPreviousHash();
            if (sPreviousHash !== undefined) {
                window.history.go(-1);
            } else {
                var oRouter = UIComponent.getRouterFor(this);
                oRouter.navTo("overview", {}, true);
            }
        },

        onRatingChange: function (oEvent) {
            var fValue = oEvent.getParameter("value");
            var oResourceBundle =
this.getView().getModel("i18n").getResourceBundle();

            MessageToast.show(oResourceBundle.getText("ratingConfirmation",
[fValue]));
        }
    });
});
```

In the `Detail` controller we load the dependency to the `sap.m.MessageToast` because we will simply display a message instead of sending the rating to the backend to keep the example simple. The event handler `onRatingChange` reads the value of our custom change event that is fired when the rating has been submitted. We then display a confirmation message with the value in a `MessageToast` control.

In the `onObjectMatched` private method, we call the `reset` method to make it possible to submit another rating as soon as the detail view is displayed for a different item.

webapp/css/style.css

```
.myAppDemoWTmyCustomButton.sapMBtn {
    margin-right: 0.125rem;
}
.myAppDemoWTmyCustomText {
    font-weight: bold;
}
/*  ProductRating */
.myAppDemoWTProductRating {
```

```
    padding: 0.75rem;
}
.myAppDemoWTProductRating .sapMRI {
    vertical-align: initial;
}
```

To layout our control, we add a little padding to the root class to have some space around the three inner controls, and we override the alignment of the `RatingIndicator` control so that it is aligned in one line with the label and the button.

We could also do this with more HTML in the renderer but this is the simplest way and it will only be applied inside our custom control. However, please be aware that the custom control is in your app and might have to be adjusted when the inner controls change in future versions of SAPUI5.

webapp/i18n/i18n.properties

```
…
# Detail Page
detailPageTitle=Walkthrough - Details
ratingConfirmation=You have rated this product with {0} stars

# Product Rating
productRatingLabelInitial=Please rate this product
productRatingLabelIndicator=Your rating: {0} out of {1}
productRatingLabelFinal=Thank you for your rating!
productRatingButton=Rate
```

The resource bundle is extended with the confirmation message and the strings that we reference inside the custom control. We can now rate a product on the detail page with our brand new control.

Conventions

- Put custom controls in the `control` folder of your app.

Step 35: Responsiveness

In this step, we improve the responsiveness of our app. SAPUI5 applications can be run on phone, tablet, and desktop devices and we can configure the application to make best use of the screen estate for each scenario. Fortunately, SAPUI5 controls like the `sap.m.Table` already deliver a lot of features that we can use.

Preview

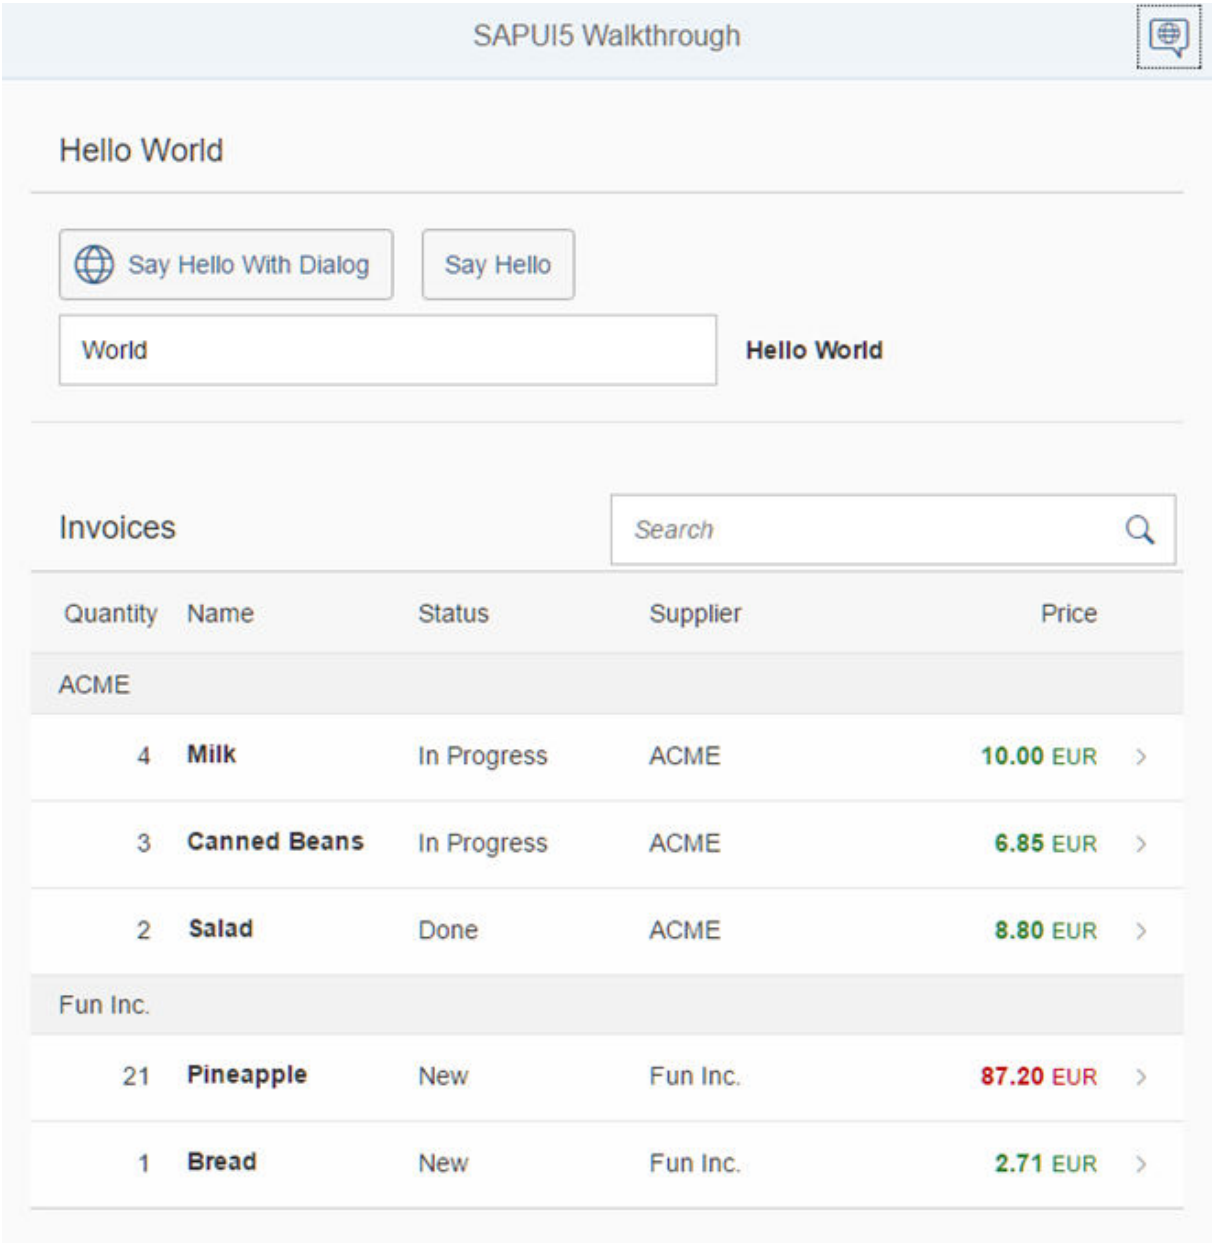

Figure 45: A responsive table is hiding some of the columns on small devices

Coding

You can view and download all files at Walkthrough - Step 35.

webapp/view/InvoiceList.view.xml

```
<mvc:View
        controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
        xmlns="sap.m"
        xmlns:mvc="sap.ui.core.mvc">
    <Table
        id="invoiceList"
        class="sapUiResponsiveMargin"
        width="auto"
        items="{
            path : 'invoice>/Invoices',
            sorter : {
                path : 'ShipperName',
                group : true
            }
        }">
        <headerToolbar>
            <Toolbar>
                <Title text="{i18n>invoiceListTitle}"/>
                <ToolbarSpacer/>
                <SearchField width="50%" search=".onFilterInvoices"/>
            </Toolbar>
        </headerToolbar>
        <columns>
            <Column
                hAlign="End"
                minScreenWidth="Small"
                demandPopin="true"
                width="4em">
                <Text text="{i18n>columnQuantity}"/>
            </Column>
            <Column>
                <Text text="{i18n>columnName}"/>
            </Column>
            <Column
                minScreenWidth="Small"
                demandPopin="true">
                <Text text="{i18n>columnStatus}"/>
            </Column>
            <Column
                minScreenWidth="Tablet"
                demandPopin="false">
                <Text text="{i18n>columnSupplier}"/>
            </Column>
            <Column
                hAlign="End">
                <Text text="{i18n>columnPrice}"/>
            </Column>
        </columns>
        <items>
            <ColumnListItem
                type="Navigation"
                press=".onPress">
                <cells>
                    <ObjectNumber number="{invoice>Quantity}"
emphasized="false"/>
```

```
                    <ObjectIdentifier title="{invoice>ProductName}"/>
                    <Text text="{
                        path: 'invoice>Status',
                        formatter: '.formatter.statusText'
                    }"/>
                    <Text text="{invoice>ShipperName}"/>
                    <ObjectNumber
                        number="{
                            parts: [{path: 'invoice>ExtendedPrice'}, {path:
'view>/currency'}],
                            type: 'sap.ui.model.type.Currency',
                            formatOptions: {
                                showMeasure: false
                            }
                        }"
                        unit="{view>/currency}"
                        state="{= ${invoice>ExtendedPrice} > 50 ? 'Error' :
'Success' }"/>
                </cells>
            </ColumnListItem>
        </items>
    </Table>
</mvc:View>
```

We exchange the list with a table simply by replacing the tag `<List>` with `<Table>`. The table has a built-in responsiveness feature that allows us to make the app more flexible. The table and the list share the same set of properties so we can simply reuse these and also the sorter.

Since a table has multiple cells in each row, we have to define columns for our table and name these according to the data. We add five `sap.m.Column` controls to the column aggregation and configure each one a bit differently:

- **Quantity**
  This column will contain a short number, so we set the alignment to `End` (which means "right" in LTR languages) and the width to `4em` which is long enough for the column description. As a description text we use a `sap.m.Text` control that references a property of the resource bundle. We set the property `minScreenWidth` to `Small` to indicate that this column is not so important on phones. We will tell the table to display this column below the main column by setting the property `demandPopin` to `true`.
- **Name**
  Our main column that has a pretty large **width** to show all the details. It will always be displayed.
- **Status**
  The status is not so important, so we also display it below the `name` field on small screens by setting `minScreenWidth` to `small` and `demandPopin` to `true`
- **Supplier**
  We completely hide the `Supplier` column on phone devices by setting `minScreenWidth` to `Tablet` and `demandPopin` to `false`.
- **Price**
  This column is always visible as it contains our invoice price.

Instead of the `ObjectListItem` that we had before, we will now split the information onto the cells that match the columns defined above. Therefore we change it to a `ColumnListItem` control with the same attributes, but now with cells aggregation. Here we create five controls to display our data:

- **Quantity**
  A simple `sap.m.ObjectNumber` control that is bound to our data field.
- **Name**
  A `sap.m.ObjectIdentifier` controls that specifies the name.

- **Status**
  A `sap.m.Text control` with the same formatter as before.
- **Supplier**
  A simple `sap.m.Text` control.
- **Price**
  An `ObjectNumber` control with the same formatter as the attributes number and `numberUnit` from the previous steps.

Now we have defined our table responsively and can see the results when we decrease the browsers screen size. The *Supplier* column is not shown on phone sizes and the two columns *Quantity* and *Status* will be shown below the name.

webapp/i18n/i18n.properties

```
...
# Invoice List
invoiceListTitle=Invoices
invoiceStatusA=New
invoiceStatusB=In Progress
invoiceStatusC=Done
columnQuantity=Quantity
columnName=Name
columnSupplier=Supplier
columnStatus=Status
columnPrice=Price
# Detail Page
...
```

We add the column names and the attribute titles to our `i18n` file.

We can see the results when we decrease the browser's screen size or open the app on a small device.

Conventions

- Optimize your application for the different screen sizes of phone, tablet, and desktop devices.

Related Information

Configuring Responsive Behavior of a Table [page 2332]

Step 36: Device Adaptation

We now configure the visibility and properties of controls based on the device that we run the application on. By making use of the `sap.ui.Device` API and defining a device model we will make the app look great on many devices.

Preview

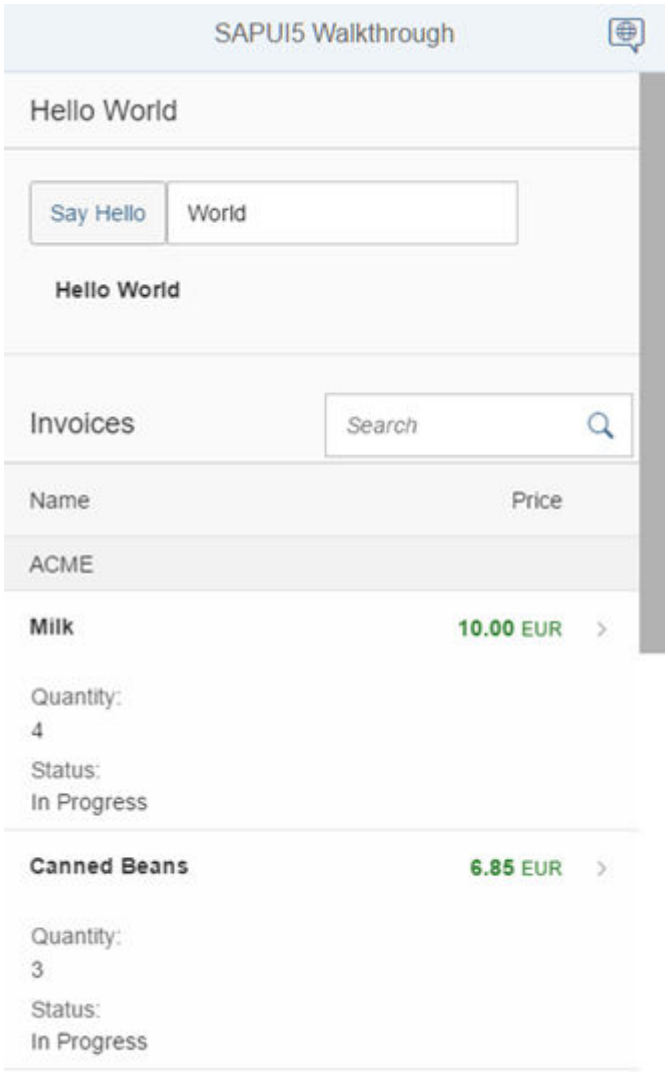

Figure 46: On phone devices, the panel is collapsed to save screen space and a button is hidden

Coding

You can view and download all files at Walkthrough - Step 36.

webapp/view/HelloPanel.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.HelloPanel"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Panel
        headerText="{i18n>helloPanelTitle}"
        class="sapUiResponsiveMargin"
        width="auto"
        expandable="{device>/system/phone}"
        expanded="{= !${device>/system/phone} }">
        <content>
            <Button
                id="helloDialogButton"
                icon="sap-icon://world"
                text="{i18n>openDialogButtonText}"
                press=".onOpenDialog"
                class="sapUiSmallMarginEnd sapUiVisibleOnlyOnDesktop"/>
            <Button
                text="{i18n>showHelloButtonText}"
                press=".onShowHello"
                class="myCustomButton"/>
            <Input
                value="{/recipient/name}"
                valueLiveUpdate="true"
                width="60%"/>
            <FormattedText
                htmlText="Hello {/recipient/name}"
                class="sapUiSmallMargin sapThemeHighlight-asColor myCustomText"/>
        </content>
    </Panel>
</mvc:View>
```

We add two new properties `expandable` and `expanded` to the `HelloPanel`. The user can now close and open the panel to have more space for the table below on devices with small screens. The property `expandable` is bound to a model named `device` and the path `/system/phone`. So the panel can be expanded on phone devices only. The device model is filled with the `sap.ui.Device` API of SAPUI5 as we see further down. The `expanded` property controls the state of the panel and we use expression binding syntax to close it on phone devices and have the panel expanded on all other devices. The device API of SAPUI5 offers more functionality to detect various device-specific settings, please have a look at the documentation for more details.

> **i Note**
>
> The `sap.ui.Device` API detects the device type (Phone, Tablet, Desktop) based on the user agent and many other properties of the device. Therefore simply reducing the screen size will not change the device type. To test this feature, you will have to enable device emulation in your browser or open it on a real device.

We can also hide single controls by device type when we set a CSS class like `sapUiVisibleOnlyOnDesktop` or `sapUiHideOnDesktop` . We only show the button that opens the dialog on desktop devices and hide it for other devices. For more options, see the documentation linked below.

webapp/Component.js

```
sap.ui.define([
    "sap/ui/core/UIComponent",
    "sap/ui/model/json/JSONModel",
    "./controller/HelloDialog",
    "sap/ui/Device"
], function (UIComponent, JSONModel, HelloDialog, Device) {
    "use strict";
    return UIComponent.extend("sap.ui.demo.walkthrough.Component", {
        metadata: {
            manifest: "json"
        },
        init: function () {
            // call the init function of the parent
            UIComponent.prototype.init.apply(this, arguments);
            // set data model
            var oData = {
                recipient: {
                    name: "World"
                }
            };
            var oModel = new JSONModel(oData);
            this.setModel(oModel);
            // disable batch grouping for v2 API of the northwind service
            this.getModel("invoice").setUseBatch(false);
            // set device model
            var oDeviceModel = new JSONModel(Device);
            oDeviceModel.setDefaultBindingMode("OneWay");
            this.setModel(oDeviceModel, "device");
            // set dialog
            this._helloDialog = new HelloDialog(this.getRootControl());
            // create the views based on the url/hash
            this.getRouter().initialize();
        },
        exit : function () {
            this._helloDialog.destroy();
            delete this._helloDialog;
        },
        openHelloDialog : function () {
            this._helloDialog.open();
        }
    });
});
```

In the `app` component we add a dependency to `sap.ui.Device` and initialize the device model in the `init` method. We can simply pass the loaded dependency `Device` to the constructor function of the JSONModel. This will make most properties of the SAPUI5 device API available as a JSON model. The model is then set on the component as a named model so that we can reference it in data binding as we have seen in the view above.

> **i Note**
>
> We have to set the binding mode to `OneWay` as the device model is read-only and we want to avoid changing the model accidentally when we bind properties of a control to it. By default, models in SAPUI5 are bidirectional (`TwoWay`). When the property changes, the bound model value is updated as well.

webapp/view/Detail.view.xml

> → Tip
>
> You can test the device specific features of your app with the developer tools of your browser. For example in Google Chrome, you can emulate a tablet or a phone easily and see the effects. Some responsive options of SAPUI5 are only set initially when loading the app, so you might have to reload your page to see the results.

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.Detail"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:wt="sap.ui.demo.walkthrough.control">
    <Page
        title="{i18n>detailPageTitle}"
        showNavButton="true"
        navButtonPress=".onNavBack">
        <ObjectHeader
            responsive="true"
            fullScreenOptimized="true"
            number="{
                parts: [{path: 'invoice>ExtendedPrice'}, {path: 'view>/
currency'}],
                type: 'sap.ui.model.type.Currency',
                formatOptions: {
                    showMeasure: false
                }
            }"
            numberUnit="{view>/currency}"
            intro="{invoice>ShipperName}"
            title="{invoice>ProductName}">
            <attributes>
                <ObjectAttribute title="{i18n>quantityTitle}"
text="{invoice>Quantity}"></ObjectAttribute>
                <ObjectAttribute title="{i18n>dateTitle}" text="{
                    path: 'invoice>ShippedDate',
                    type: 'sap.ui.model.type.Date',
                    formatOptions: {
                      style: 'long',
                      source: {
                        pattern: 'yyyy-MM-ddTHH:mm:ss'
                      }
                    }
                  }"/>
            </attributes>
        </ObjectHeader>
        <wt:ProductRating id="rating" class="sapUiSmallMarginBeginEnd"
change=".onRatingChange"/>
    </Page>
</mvc:View>
```

Some controls already have built-in responsive features that can be configured. The `ObjectHeader` control can be put in a more flexible mode by setting the attribute `responsive` to `true` and `fullScreenOptimized` to true as well. This will show the data that we add to the view now at different positions on the screen based on the device size.

We add the `number` and `numberUnit` field from the list of the previous steps also to the `ObjectHeader` and use the same formatter with the `currency` type as in the previous steps. We then define two attributes: The quantity of the invoice and the shipped date which is part of the data model. We have not used this `shippedDate` field from the invoices JSON file so far, it contains a date in typical string format.

We now use the `Date` type and provide the pattern of our date format in the source section of the format options. It will display a more human-readable formatted date text that also fits to small screen devices.

webapp/controller/Detail.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/core/routing/History",
    "sap/m/MessageToast",
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/UIComponent"
], function (Controller, History, MessageToast, JSONModel, UIComponent) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.Detail", {
        onInit : function () {
            var oViewModel = new JSONModel({
                currency: "EUR"
            });
            this.getView().setModel(oViewModel, "view");
            var oRouter = sap.ui.core.UIComponent.getRouterFor(this);

oRouter.getRoute("detail").attachPatternMatched(this._onObjectMatched, this);
        },
        _onObjectMatched : …
});
```

In the `Detail` controller we simply add the view model with our currency definition to display the number properly. It is the same code as in the `InvoiceList` controller file.

webapp/i18n/i18n.properties

```
# Detail Page
detailPageTitle=Walkthrough - Details
ratingConfirmation=You have rated this product with {0} stars
dateTitle=Order date
quantityTitle=Quantity
```

We add the column names and the attribute titles to our `i18n` file.

We can see the results when we decrease the browser's screen size or open the app on a small device.

Conventions

Optimize your application for the different screen sizes of phone, tablet, and desktop devices.

Related Information

API Reference: `sap.ui.Device.media.RANGESETS`
API Reference: `sap.ui.Device`

Step 37: Content Density

In this step of our Walkthrough tutorial, we adjust the content density based on the user's device. SAPUI5 contains different content densities allowing you to display larger controls for touch-enabled devices and a smaller, more compact design for devices that are operated by mouse. In our app, we will detect the device and adjust the density accordingly.

Preview

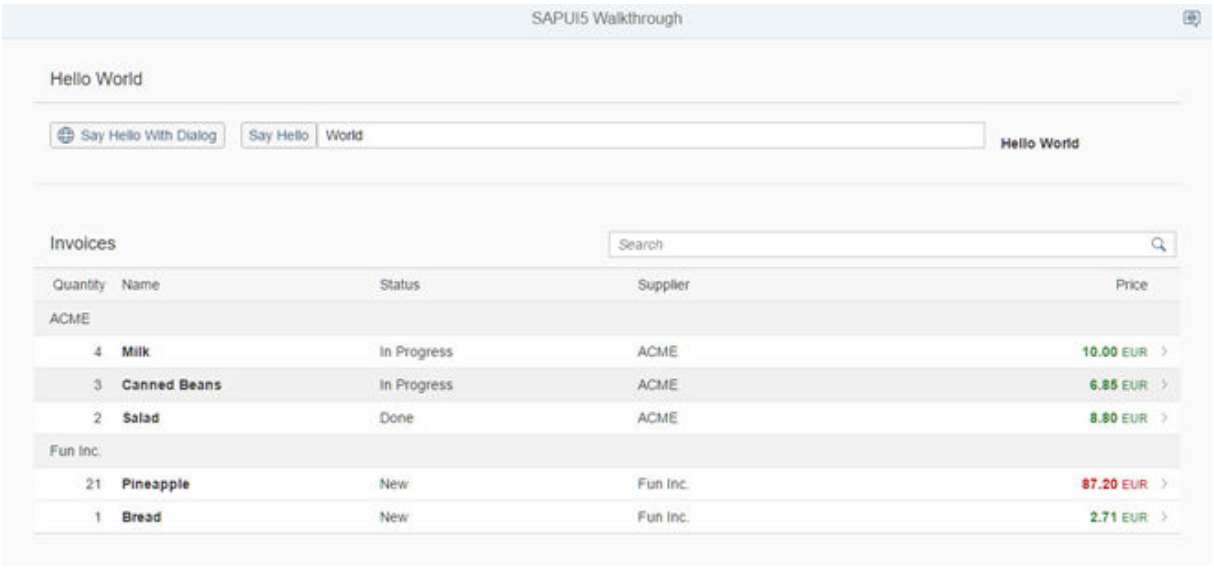

Figure 47: The content density is compact on desktop devices and cozy on touch-enabled devices

Coding

You can view and download all files at Walkthrough - Step 37.

webapp/Component.js

```
...
        init: function () {
...         },
```

```
...
        getContentDensityClass : function () {
            if (!this._sContentDensityClass) {
                if (!Device.support.touch) {
                    this._sContentDensityClass = "sapUiSizeCompact";
                } else {
                    this._sContentDensityClass = "sapUiSizeCozy";
                }
            }
            return this._sContentDensityClass;
        }
    });
});
```

To prepare the content density feature we will also add a helper method `getContentDensityClass`. SAPUI5 controls can be displayed in multiple sizes, for example in a `compact` size that is optimized for desktop and non-touch devices, and in a `cozy` mode that is optimized for touch interaction. The controls look for a specific CSS class in the HTML structure of the application to adjust their size.

This helper method queries the `Device` API directly for touch support of the client and returns the CSS class `sapUiSizeCompact` if touch interaction is not supported and `sapUiSizeCozy` for all other cases. We will use it throughout the application coding to set the proper content density CSS class.

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function (Controller) {
    "use strict";
    return Controller.extend("sap.ui.demo.walkthrough.controller.App", {
        onInit: function () {

this.getView().addStyleClass(this.getOwnerComponent().getContentDensityClass());
        },
        onOpenDialog: function () {
            this.getOwnerComponent().openHelloDialog();
        }
    });
});
```

We add a method `onInit` on the app controller that is called when the app view is instantiated. There we query the helper function that we defined on the app component to set the corresponding style class on the app view, All controls inside the app view will now automatically adjust either to the compact or cozy size as defined by the style.

webapp/controller/HelloDialog.js

```
sap.ui.define([
    "sap/ui/base/ManagedObject",
    "sap/ui/core/Fragment",
    "sap/ui/core/syncStyleClass"
], function (ManagedObject, Fragment, syncStyleClass) {
    "use strict";
```

```
    return
ManagedObject.extend("sap.ui.demo.walkthrough.controller.HelloDialog", {
        constructor : function (oView) {
            this._oView = oView;
        },
        exit : function () {
            delete this._oView;
        },
        open : function () {
            var oView = this._oView;
            // create dialog lazily
            if (!oView.byId("helloDialog")) {
                var oFragmentController = {
                    onCloseDialog : function () {
                        oView.byId("helloDialog").close();
                    }
                };
                // load asynchronous XML fragment
                Fragment.load({
                    id: oView.getId(),
                    name: "sap.ui.demo.walkthrough.view.HelloDialog",
                    controller: oFragmentController
                }).then(function (oDialog){
                    // connect dialog to the root view of this component
(models, lifecycle)
                    oView.addDependent(oDialog);
                    // forward compact/cozy style into dialog

syncStyleClass(oView.getController().getOwnerComponent().getContentDensityClass()
, oView, oDialog);
                    oDialog.open();
                });
            } else {
                oView.byId("helloDialog").open();
            }
        }
    });
});
```

The "Hello World" dialog is not part of the `app` view but opened in a special part of the DOM called "static area". The content density class defined on the `app` view is not known to the dialog so we sync the style class of the app with the dialog manually.

webapp/manifest.json

```
...
  "sap.ui5": {
    ...
    "dependencies": {
      ...
    },
    "contentDensities": {
      "compact": true,
      "cozy": true
    }
  }
```

In the `contentDensities` section of the `sap.ui5` namespace, we specify the modes that the application supports. Containers like the SAP Fiori launchpad allow switching the content density based on these settings.

As we have just enabled the app to run in both modes depending on the devices capabilities, we can set both to `true` in the application descriptor.

Summary

You should now be familiar with the major development paradigms and concepts of SAPUI5 and have created a very simple first app. You are now ready to build a proper app based on what you've learned.

If you want to dive deeper into specific topics, you can use the other tutorials that show some of the aspects of this Walkthrough and advanced topics in more detail.

API Reference: `sap.ui.Device`
API Reference: `jQuery.sap.syncStyleClass`

Step 38: Accessibility

As the last step in this tutorial, we are going to improve the accessibility of our app.

To achieve this, we will add ARIA attributes. ARIA attributes are used by screen readers to recognize the application structure and to interpret UI elements properly. That way, we can make our app more accessible for users who are limited in their use of computers, for example visually impaired persons. The main goal here is to make our app usable for as many people as we can.

> → Tip
>
> ARIA is short for **Accessible Rich Internet Applications**. It is a set of attributes that enable us to make apps more accessible by assigning semantic characteristics to certain elements. For more information, see Accessible Rich Internet Applications (ARIA) – Part 1: Introduction.

Preview

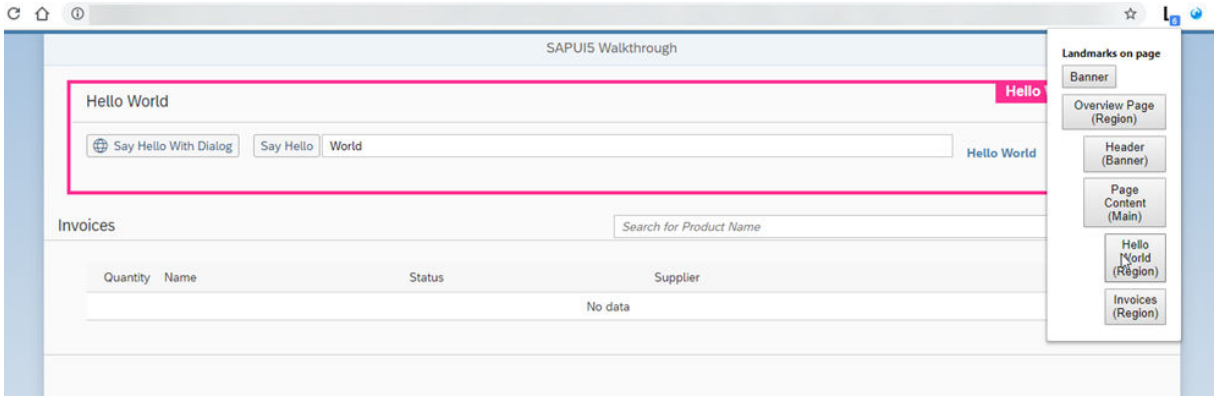

Figure 48: Landmarks in our app

Coding

You can view and download all files at Walkthrough - Step 38.

One part of the ARIA attribute set is the so-called landmarks. You can compare landmarks to maps in that they help the user navigate through an app. For this step, we will use Google Chrome with a free landmark navigation extension We will now add meaningful landmarks to our code.

webapp/view/Overview.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page title="{i18n>homePageTitle}">
        <landmarkInfo>
            <PageAccessibleLandmarkInfo
                rootRole="Region"
                rootLabel="{i18n>Overview_rootLabel}"
                contentRole="Main"
                contentLabel="{i18n>Overview_contentLabel}"
                headerRole="Banner"
                headerLabel="{i18n>Overview_headerLabel}"/>
        </landmarkInfo>
        <headerContent>
            ...
        </headerContent>
        <content>
            ...
        </content>
    </Page>
</mvc:View>
```

We use `sap.m.PageAccessibleLandmarkInfo` to define ARIA roles and labels for the overview page areas. For more information, see the API Reference: `sap.m.PageAccessibleLandmarkInfo`.

webapp/view/InvoiceList.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.InvoiceList"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Panel accessibleRole="Region">
        <headerToolbar>
            <Toolbar>
                <Title text="{i18n>invoiceListTitle}"/>
                <ToolbarSpacer/>
                <SearchField
                    width="50%"
                    search=".onFilterInvoices"
                    ariaLabelledBy="searchFieldLabel"
                    ariaDescribedBy="searchFieldDescription"
                    placeholder="{i18n>searchFieldPlaceholder}"/>
            </Toolbar>
        </headerToolbar>
        <Table
            id="invoiceList"
            class="sapUiResponsiveMargin"
            width="auto"
            items="{
                path : 'invoice>/Invoices',
                sorter : {
                    path : 'ShipperName',
                    group : true
                }
            }">
            <columns>
                <Column
                    hAlign="End"
    …
            </columns>
        </Table>
    </Panel>
</mvc:View>
```

We add a `sap.m.Panel` around the invoice list, and we move the toolbar from the table into the panel so the region can take the title of the toolbar as its own. This has the effect that it will now be a region in our landmarks.

webapp/view/HelloPanel.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.walkthrough.controller.HelloPanel"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Panel
        headerText="{i18n>helloPanelTitle}"
        class="sapUiResponsiveMargin"
        width="auto"
        expandable="{device>/system/phone}"
        expanded="{= !${device>/system/phone} }"
        accessibleRole="Region">
        …
    </Panel>
</mvc:View>
```

In this view, we already have a panel, so we just add the `accessibleRole` attribute.

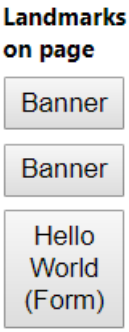
> **i** Note
>
> To add ARIA roles, labels and panels to other views, for example your `Detail.view.xml`, you can follow the same pattern. We won't go into detail in this tutorial step, but if you're interested, simply download the tutorial code and take a look at the `Detail.view.xml`.

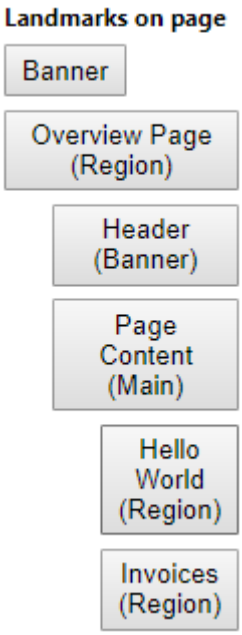
webapp/i18n/i18n.properties

```
...
#Overview Page
Overview_rootLabel=Overview Page
Overview_headerLabel=Header
Overview_contentLabel=Page Content
ratingTitle=Rate the Product
...
```

Here, we add the text for the rating panel title and the labels for the ARIA regions to the text bundle.

Result





Landmarks on the overview page - before	Landmarks on the overview page - after

As you can see, we now have four landmarks on our page. The top three landmarks structure our page:

- *Overview Page* marks the complete page.
- *Header* marks the page title.
- *Page Content* marks the content of our page. This landmark already has two children.

Congratulations!

You've completed the walkthrough, good job! You should be familiar with all major development paradigms of SAPUI5 now. Our other tutorials focus on certain aspects of SAPUI5, so feel free to explore!

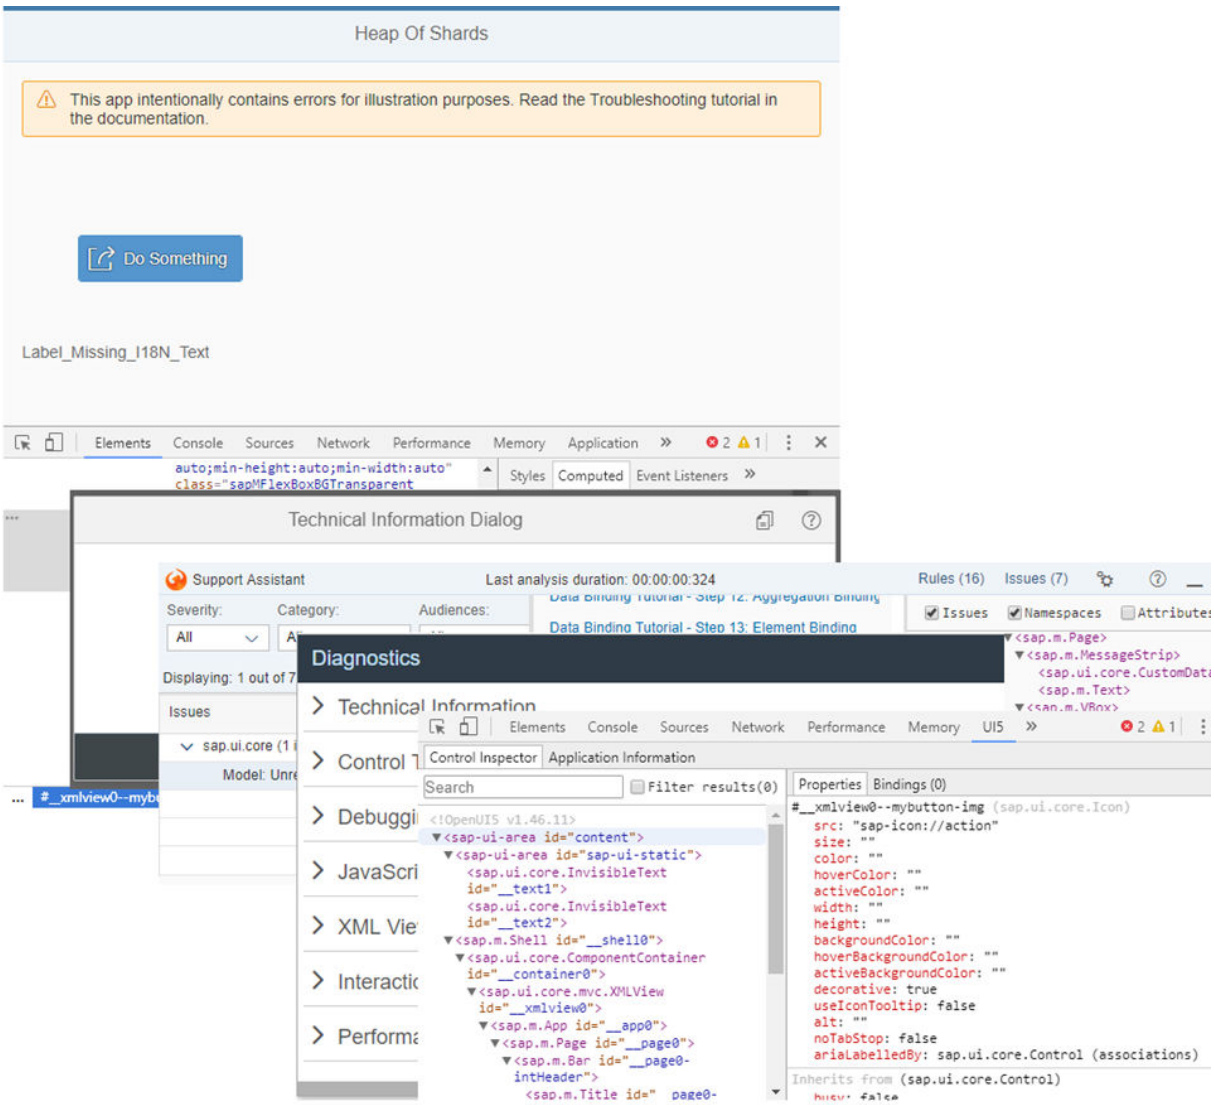
SAP Software Accessibility

Troubleshooting

In this tutorial, we will show you some tools that will help you if you run into problems with your SAPUI5 app.

We will introduce you to the browser developer tools and show you the various tools that SAPUI5 offers.



For example, the SAPUI5 tools can help you with the following tasks:

- Inspect and debug apps
- Examine bugs and analyze errors
- Simulate UI changes
- Find out how to improve performance

To help you practice using the tools, we created an app with errors that we will use throughout the tutorial. You can view and download the app in the Demo Kit at Troubleshooting.

Get Help

If you're stuck and need help with a development task, you can also post a question in the SAPUI5-related forums, for example in the SAP Community or on Stack Overflow.

Step 1: Browser Developer Tools

In this step, you will learn how to use your browser's developers tools to troubleshoot your SAPUI5 app.

Most modern web browsers contain some form of Developer Tools. They allow you to examine the details of the current web page. You can also use them to debug JavaScript code, analyze network performance, live-edit DOM elements, and much more. As an example, we will show you how to use the *Developer Tools* in Google Chrome. Other browsers have similar capabilities, and you can easily adapt the examples shown here to these browsers.

Opening the Example App and the Developer Tools

1. Download the example app with errors from the Demo Kit at Troubleshooting and run the app.

   > **i Note**
   >
   > If you run the app within the Demo Kit frame, this step will not work as described. Open the app in a new tab first with  .

2. Open the *Developer Tools* by pressing `F12`.

Inspecting DOM Elements and CSS Styles in the *Elements* Tab

1. Activate the *Inspect Element* mode by pressing `Ctrl` + `Shift` + `C`.
2. Click the *Do Something* button in the app.
   The DOM tree in the *Elements* tab highlights the button's DOM element. Depending on which part of the button (icon or text) you clicked, different HTML tags are highlighted.
3. Search for the following line:

   ```
   <button id="container-HeapOfShards---app--myButton" data-sap-ui="container-
   HeapOfShards---app--myButton" aria-describedby="__text1"
       class="sapMBtn sapMBtnBase sapMBtnInverted">
   </button>
   ```

   The *Styles* section in the panel on the right shows the active and overruled (striked-through) CSS styles for the DOM element that is currently selected.
4. In the *Styles* section, switch to the *Computed* tab.
   You can see that the `margin` of the button is set to `0px`.
5. In the context menu of the element, choose *Edit as HTML* and add `sapUiLargeMargin` to the `class` section of the `button` tag.
   You can immediately see the effect on the web page.
   The edited element should now look like this:

   ```
   <button id="container-HeapOfShards---app--myButton" data-sap-ui="container-
   HeapOfShards---app--myButton" aria-describedby="__text1"
       class="sapMBtn sapMBtnBase sapMBtnInverted sapUiLargeMargin">
   ```

```
</button>
```

6. In the *Styles* section, switch again to the *Computed* tab.
   You can see that the `margin` of the button is now set to `48px`.

Analyzing Messages in the *Console* Tab

Interacting with the document

1. Switch to the *Console* tab and enter `$("#container-HeapOfShards---app--myButton")`
   The console displays the DOM element structure of the button:

```
Q.fn.init [button#container-HeapOfShards---app--
myButton.sapMBtn.sapMBtnBase.sapMBtnInverted,
context: document, selector: "#container-HeapOfShards---app--myButton"]
```

2. Examine the `button` element by expanding the structure.
3. On the *Console* tab, enter `myView=sap.ui.getCore().byId("container-HeapOfShards---app").`
4. On the *Console* tab, enter `myView.byId("myButton").`
   The console displays the SAPUI5 structure of the button control:

```
f {bAllowTextSelection: true, mEventRegistry: {…},
sId: "container-HeapOfShards---app--myButton", mProperties: PropertyBag,
mAggregations: {…}, …}
```

   Examine the SAPUI5 structure by expanding it.

> **i Note**
>
> The method of retrieval is different for SAPUI5 controls and DOM elements:

SAPUI5 Control	DOM Element
`sap.ui.getCore().byId("container-HeapOfShards---app--myButton")`	`jQuery("#container-HeapOfShards---app--myButton")`

Watching messages

1. Switch to the *Console* tab.
2. Click the *Do Something* button in the app.
   A `MessageToast` appears with the text *Sorry, an error occurred!*.
3. In the console, you see the following error message:

```
TypeError: oEvent.getSourceXYZ is not a function
at f.onPress (http://.../App.controller.js?eval:20:69)
...
```

   This means that an error occurred in the `onPress` function in the `App.controller.js` file at line `20`.
4. Click the first link in the stack trace after `f.onPress` to look at the source code where you can see that it wasn't the generic `getSource` function that was called, but an undefined `getSourceXYZ`.

```
sMessage = this.getResourceBundle().getText("buttonOk",
[oEvent.getSourceXYZ().getId()])
```

Debugging in the *Sources* Tab

1. Switch to the *Source* tab.
2. To view the source of the `App.controller` file, press `Ctrl` + `P`, enter `App.controller`, and select `App.controller.js?eval`.
3. Set a breakpoint in line 20 by clicking on the line number of the following line:

```
sMessage = this.getResourceBundle().getText("buttonOk",
[oEvent.getSourceXYZ().getId()]);
```

4. Click the *Do Something* button in the app.
   The debugger stops at line 20.
5. In line 20, replace `getSourceXYZ()` with `getSource()` and press `Ctrl` + `S`:

```
sMessage = this.getResourceBundle().getText("buttonOk",
[oEvent.getSource XYZ().getId()]);
```

6. Resume the execution of the code by pressing `F8`.
   The message toast is now displayed on the web page with the following message: *"HeapOfShards---app--myButton" pressed*

> **i Note**
>
> You can also use the *Pause on exception* button and select *Pause on caught exceptions* on the top right of the *Sources* tab to pause the execution before an exception occurs without setting breakpoints.

Checking the *Network* Tab

The *Network* tab shows the sequence and duration of files being loaded. It can be used to optimize loading performance and debug request issues.

1. Switch to the *Network* tab.
2. Press `F5` to reload the page.
   You see a list of the files that are currently loaded.
   You can see that the `NavigationBar.js` file is loaded, but the view does not contain any `NavigationBar` elements so it is not used.
3. You can't edit the code directly in this tab. You have to fix the source files in your development environment and then reload the app.
   Remove the unnecessary reference to the `NavigationBar` in the `App.controller` file:

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    'sap/m/MessageToast',
    'sap/ui/ux3/NavigationBar',
    'jquery.sap.global'
], function(Controller, MessageToast, NavigationBar, jQuery) {
...
```

Testing Responsiveness with *Device Mode*

Switch to *Device* mode by clicking the respective button or by pressing `Ctrl` + `Shift` + `M`.

Emulate different mobile devices by selecting different devices, or switch orientation from landscape to portrait.

Analyzing Performance Problems and Memory Leaks

There are additional tabs that can help you to analyze performance problems or memory leaks. For more information, refer to the documentation of the developer tools of your browser.

- *Memory* or *Profiles*
- *Performance* or *Timeline*
- *Application* or *Resources*

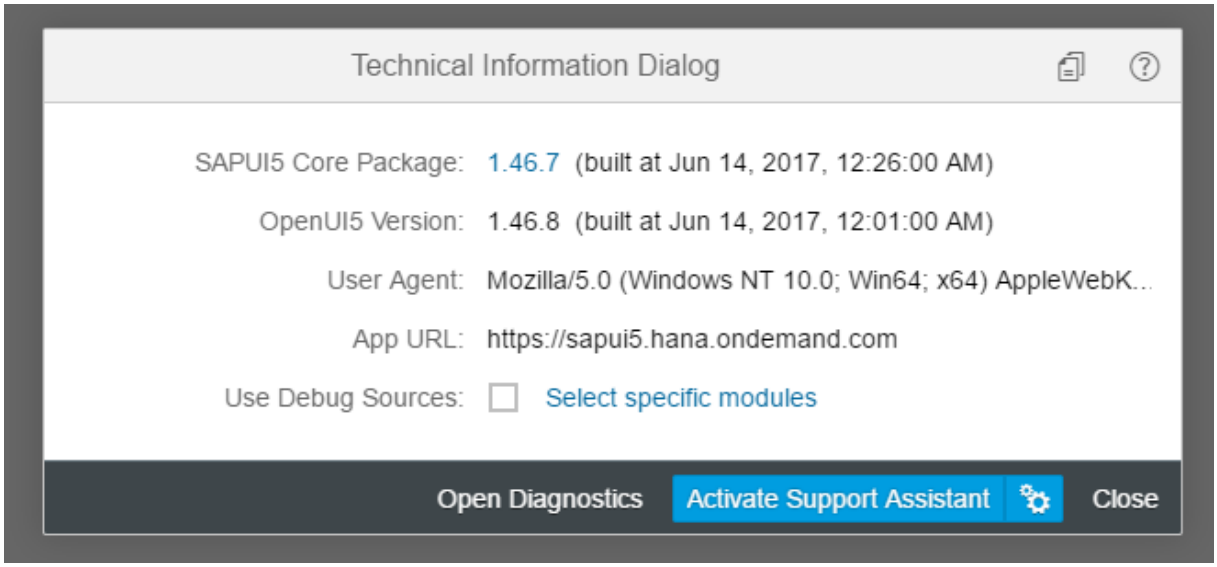
Related Information

Documentation of the Chrome DevTools on `https://developers.google.com`

Step 2: Technical Information Dialog

In this tutorial step, we will have a closer look at the "Technical Information Dialog". This tool comes in handy whenever you want to know the technical details of the running application, and also has some other useful features.

Preview



Opening the Example App and the Technical Information Dialog

1. Download the example app with errors from the Demo Kit at Troubleshooting and run the app.
2. Open the *Technical Information Dialog* by pressing `Ctrl` + `Shift` + `Alt` + `P`.

The dialog box shows information related to the app and provides access to additional support options.

Checking the SAPUI5 Version

When you run into problems with your app, you should check the SAPUI5 version that you're using. The feature that you want to use may not be available in your version or may have some bugs that are already solved in a later version.

1. Check the displayed version information for the*SAPUI5 Core Package* and the *OpenUI5 Version*.
2. Open the version overview at https://ui5.sap.com/versionoverview.html to see if there are newer patch levels or releases of SAPUI5.
3. Read the What's New [page 6] section in the documentation and check the Change Log to find information about new features and bug fixes.

> **i Note**
>
> You can view a specific version of the Demo Kit by adding the version number to the URL, for example, `https://ui5.sap.com/1.38.8/`.

For more information, see Versioning of SAPUI5 [page 29].

Checking the Device

The device on which you run the app may not be supported or might be detected incorrectly by SAPUI5. This can lead to issues with responsiveness or device adaption.

1. Verify that the *User Agent* shown in the dialog box matches your device, browser, and operating system. If the information is truncated because there is not enough space, you can see the full string as a tooltip. To copy the information, use the *Copy technical information to clipboard* button.
2. Test the functionality on another device or by using the device emulation features that are offered in the developer tools of your browser.

Turning On Debug Sources

The SAPUI5 libraries are included in your app in a compressed form. To be able to efficiently debug these libraries, they have to be reloaded in their source format and with developer comments.

1. Select the *Use Debug Sources* checkbox and confirm reloading the app.

2. Open the developer tools of your browser
3. Choose Crtl + O and type the name of an SAPUI5 framework artifact to display its source code in debug mode.

> **i Note**
>
> You may see additional errors and warnings in the developer console. These can help you investigate the problem further.
>
> For performance reasons, you should deactivate this feature again when you're done.

You can also select debug mode only for specific packages:

1. Next to the *Use Debug Sources* checkbox, choose *Select specific modules* to open the selection dialog box.
2. Select one or more modules in the module tree and notice that the value of the input field changes accordingly.
3. Apply the selection and reload the app.

Only the selected modules are now loaded in debug mode.

Copying Technical Info

If you're really stuck or have found a bug, you can open a ticket. Choose the *Copy technical information to clipboard* button to copy the technical details from this dialog box and then attach them to your message.

Accessing Other Tools

The *Technical Information Dialog* also includes links to *Diagnostics* and *Support Assistant* that we will discuss in the following steps of this tutorial.

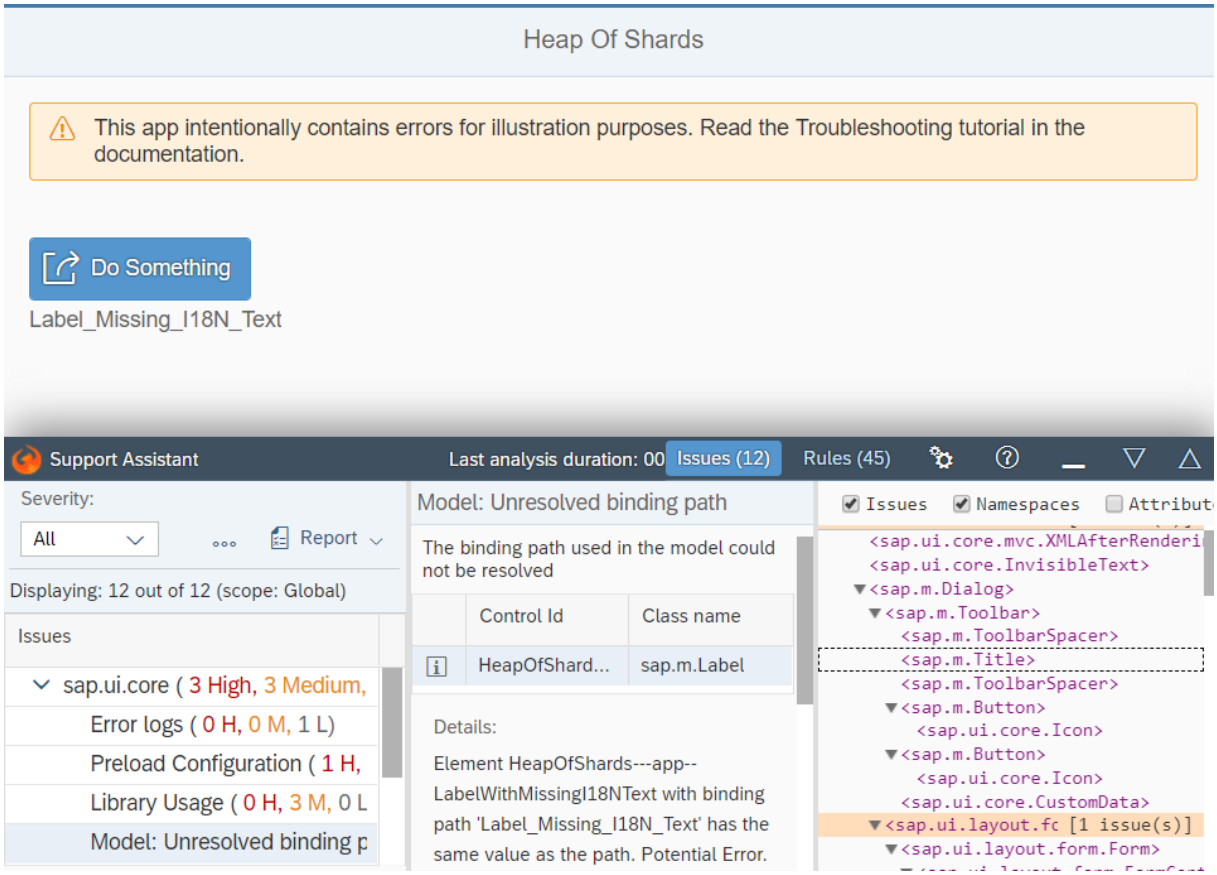
Related Information

Technical Information Dialog [page 1322]

Step 3: Support Assistant

In this tutorial step, we will have a closer look at Support Assistant. You can use this tool to check whether your app is built according to the best practices with predefined rules.

Preview



Opening the Example App and Support Assistant

1. Download the example app with errors from the Demo Kit at Troubleshooting and run the app.
2. Activate the Support Assistant using one of the following options:
   - Open the *Technical Information Dialog* by pressing `Ctrl` + `Shift` + `Alt` + `P` and choose *Activate Support Assistant*.
   - Use the URL parameter: `sap-ui-support=true`.

   The Support Assistant toolbar opens in the footer of the app.

Analyzing and Fixing Issues

1. In the *Support Assistant* toolbar, choose *Rules*.
2. In the *Available Rules* tab, select all rules, and choose *Analyze*.
   You now see a list of issues.
3. Select *Model: Unresolved binding path* in the list of issues. In the issue details, you see the following message: *Element HeapOfShards---app--LabelWithMissingI18NText with binding path 'Label_Missing_I18N_Text' has the same value as the path. Potential Error.*
4. Open the `i18n.properties` file in your development environment and add the missing text.

   ```
   […]
   item1Text=Item 1
   item2Text=Item 2
   selectEventMessage=Event "{0}" fired.
   Label_Missing_I18N_Text=Label Text
   ```

   For more information, see Walkthrough Step 8: Translatable Texts [page 85]
5. Restart the app and start the analysis again. This issue should now be gone. We have intentionally hidden some more errors in the code - check and see if you can find and correct them.

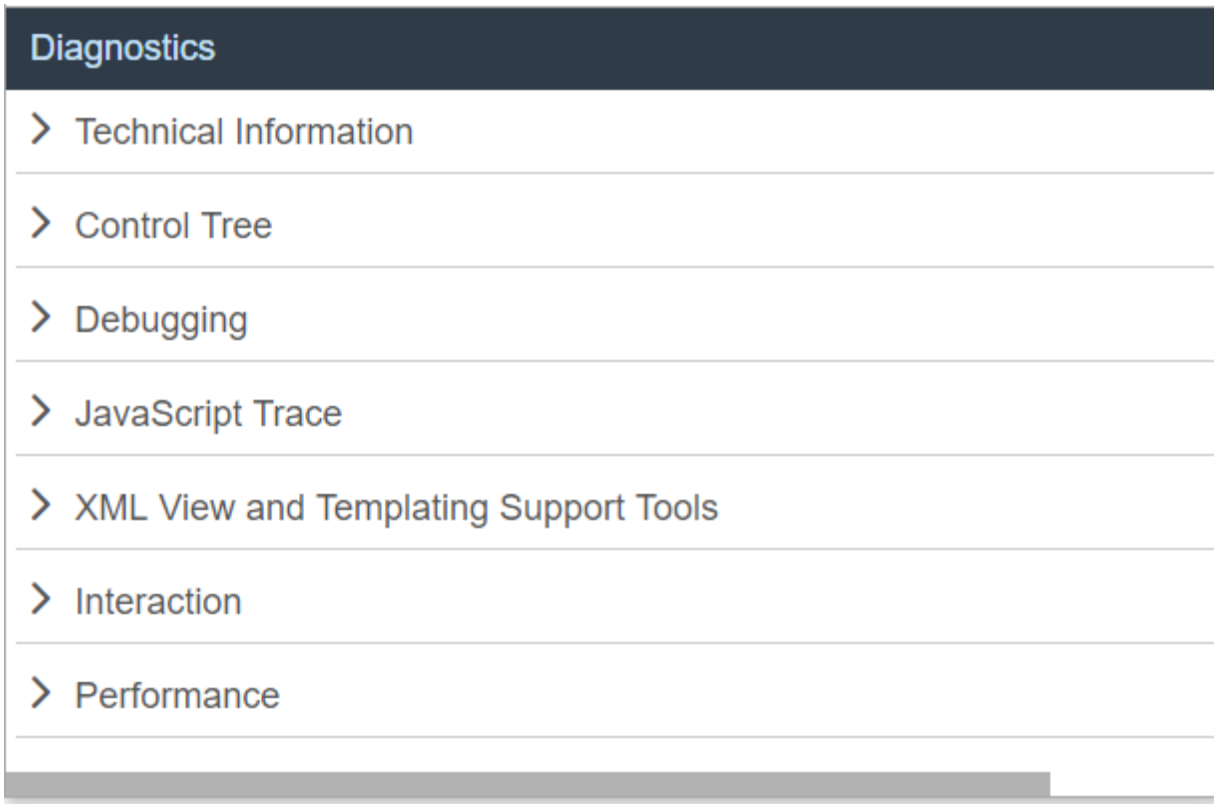
Related Information

Support Assistant [page 1339]

Step 4: Diagnostics Window

In this tutorial step, we have a closer look at the Diagnostics window. It offers a wealth of information including comprehensive technical information, a control tree, and debugging features.

Preview



Opening the Example App and the Diagnostics Window

1. Download the example app with errors from the Demo Kit at Troubleshooting and run the app.
2. Open the *Diagnostics* window by pressing `Ctrl` + `Shift` + `Alt` + `S`.

Improving App Performance

Let's say that you are facing a performance issue in your app, so let's check some performance-relevant settings in the *Diagnostics* window:

1. Expand the *Technical Information* section and scroll down to view the loaded libraries.
2. If you spot any libraries that you originally defined, but you don't actually use, remove them from the `manifest.json` file in your development environment to prevent them from loading. In this case, you can see that the example app loads the `sap.ui.layout` library, even though the `layout` control is not used.
3. Scroll to the *Configuration (bootstrap)* section. You see that the `preload` method is set to synchronous processing.
4. To improve performance, set the bootstrap parameter `data-sap-ui-async` to `true` in the `index.html` file.

```
<!DOCTYPE HTML>
<html>
<head>
    <meta charset="utf-8">
    <meta name="viewport" content="width=device-width, initial-scale=1.0">
    <title>Heap Of Shards</title>
    <!-- set data-sap-ui-async="true" to enable the user to fix it in the
    troubleshooting tutorial step 4: Diagnostics Window -->
    <script id="sap-ui-bootstrap"
        src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-libs="sap.f"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.HeapOfShards": "./",
            "sap.ui.demo.DoesNotExist": "./DoesNotExist"
        }'
        data-sap-ui-oninit="module:sap/ui/core/ComponentSupport"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true">
    </script>
[…]
```

Simulating UI Changes

The app contains a *Do Something* button and you want to make the button bigger. The control tree allows you to test which width is the best.

1. Expand the *Control Tree* section. Make sure that you display both the app and the *Diagnostics* windows side-by-side or on different monitors. Otherwise the diagnostics window will go to the background.
2. Press and hold the `Ctrl` + `Shift` + `Alt` keys and click the *Do Something* button in the app. You see the button blinking green.
3. In the control tree of the *Diagnostics* window, the button is selected and you can see its properties on the right.
4. Change the value of the `width` property to `100%` and confirm with `Enter`.
   The button width is automatically increased.
5. The changes that you make in the *Diagnostics* window are only temporary. To make your change permanent, you have to change the app code.

Trying Different SAPUI5 Versions

If you find a bug in your application, you can easily check whether it has already been fixed in a newer SAPUI5 version. Just try the app with a different SAPUI5 version:

1. Expand the *Technical Information* section and check the loaded version.
2. Expand the *Debugging* section.
3. Choose *Other* from the *Boot application with different UI5 version on next reload* dropdown list.
4. Enter a custom URL, for example `https://openui5.hana.ondemand.com/1.46.6/resources/sap-ui-core.js`.
5. Choose *Activate Reboot URL*, confirm the dialog box, and reload the app.
6. Reopen the *Diagnostics* window and expand the *Technical Information* section. The loaded SAPUI5 version is now changed.

More Features

More features are waiting for you to discover in the *Diagnostics* window. For more information, see Diagnostics [page 1326].

Step 5: UI5 Inspector

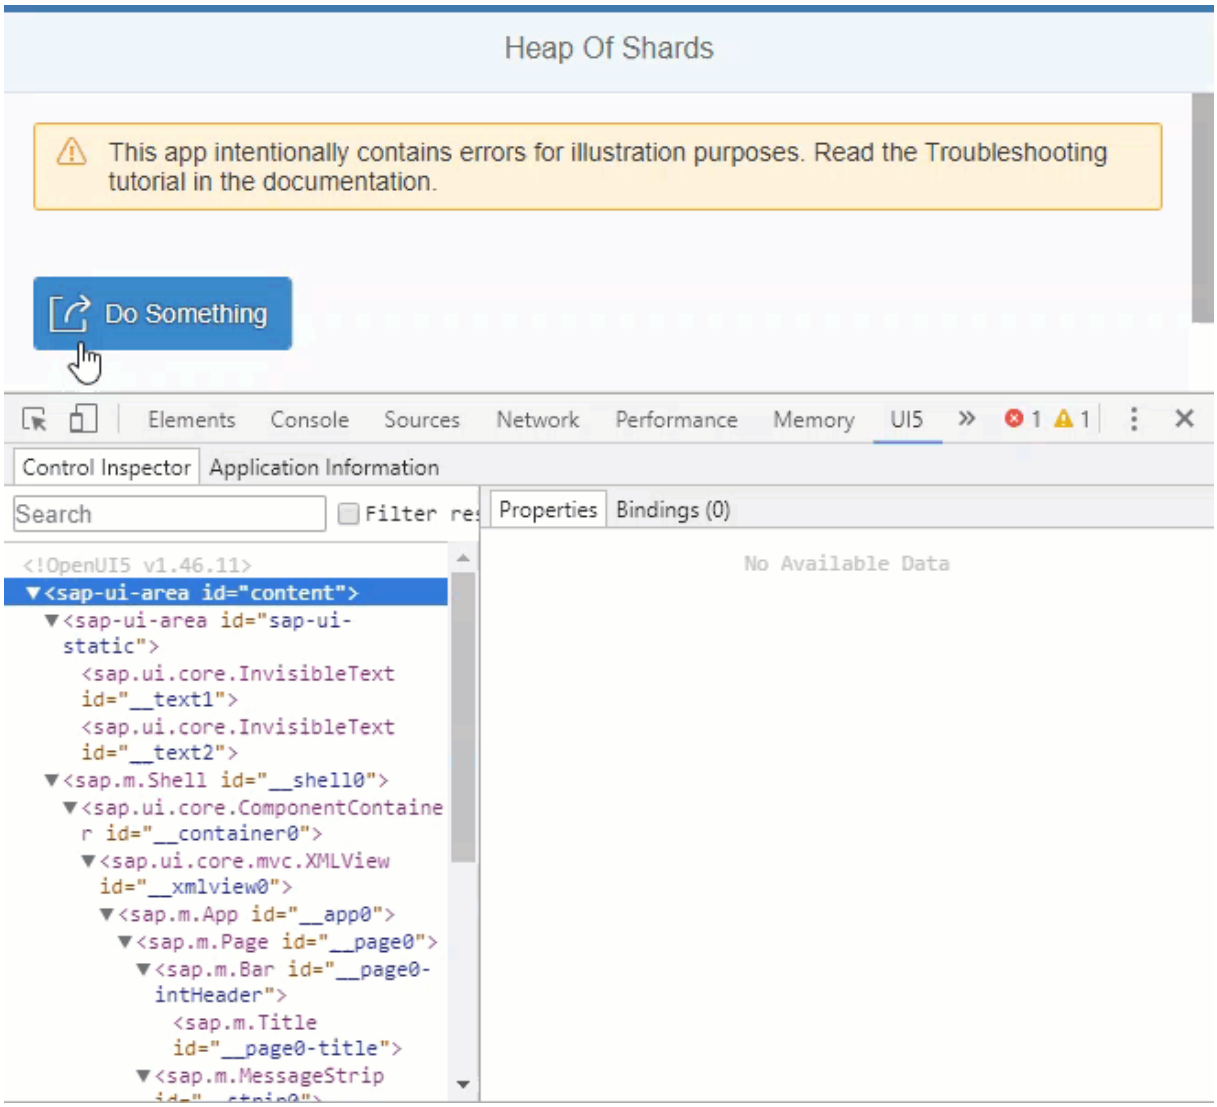
In this tutorial step, we will have a closer look at UI5 Inspector - a plug-in specifically created for analyzing and debugging SAPUI5 code.

With UI Inspector, you can find answers to the following questions, for example:

- What is the structure of your app?
- How are the elements related to each other?
- Which controls are involved when a function is performed?
- Which data is bound to a specific control and how (model and path)?

> **i Note**
>
> UI5 Inspector is only available for the Google Chrome browser.

Preview



Opening the Example App and the UI5 Inspector

1. Download UI5 Inspector from the Chrome Web Store and add it to your Chrome browser as a standard extension .
2. Download the example app with errors from the Demo Kit at Troubleshooting and run the app.
3. Open the *Developer Tools* in Google Chrome by pressing `F12`.
4. Choose the *UI5* tab on the right side of the developer tools panel.
5. Choose *Control Inspector*.
   You now see a list of all of the controls that are used in the current view of the app. When you select an entry, you see the properties and their values in the *Properties* area on the right. You can analyze line by line without being overwhelmed by too much information.

Simulating UI Changes

The app contains a *Do Something* button with meaningless icon (`sap-icon://action`) and text. We want to use the `sap-icon://activate` icon instead and change the text. With UI Inspector, we want to simulate how that will effect the UI change.

1. Right-click the *Do Something* button and from the context menu select *Inspect UI5 Control*.
   The corresponding line in the *Control Inspector* is highlighted and you can view its properties.
2. Double-click the value for the `icon` property, which is currently `sap-icon://action`.
3. Replace `action` with `activate` and confirm with `Enter`.

   The icon on the button in the app is updated to show the new icon  .
4. Double-click the value for the `text` property and change the value to `Activate`.
5. The changes that you make in the UI5 Inspector are only temporary, and the icon will be reset to the default when the page is reloaded. To make your change permanent, you have to change the app code.

Related Information

UI5 Inspector [page 1374]

First-Aid Kit

This section contains the most common issues that you might face when developing SAPUI5 apps and how to solve them.

An Empty Page Comes Up

You find yourself in one of these situations:

- The browser shows an empty page: there's no content and no error message is displayed
- An `Uncaught Error` message is shown in the developer console

Preview

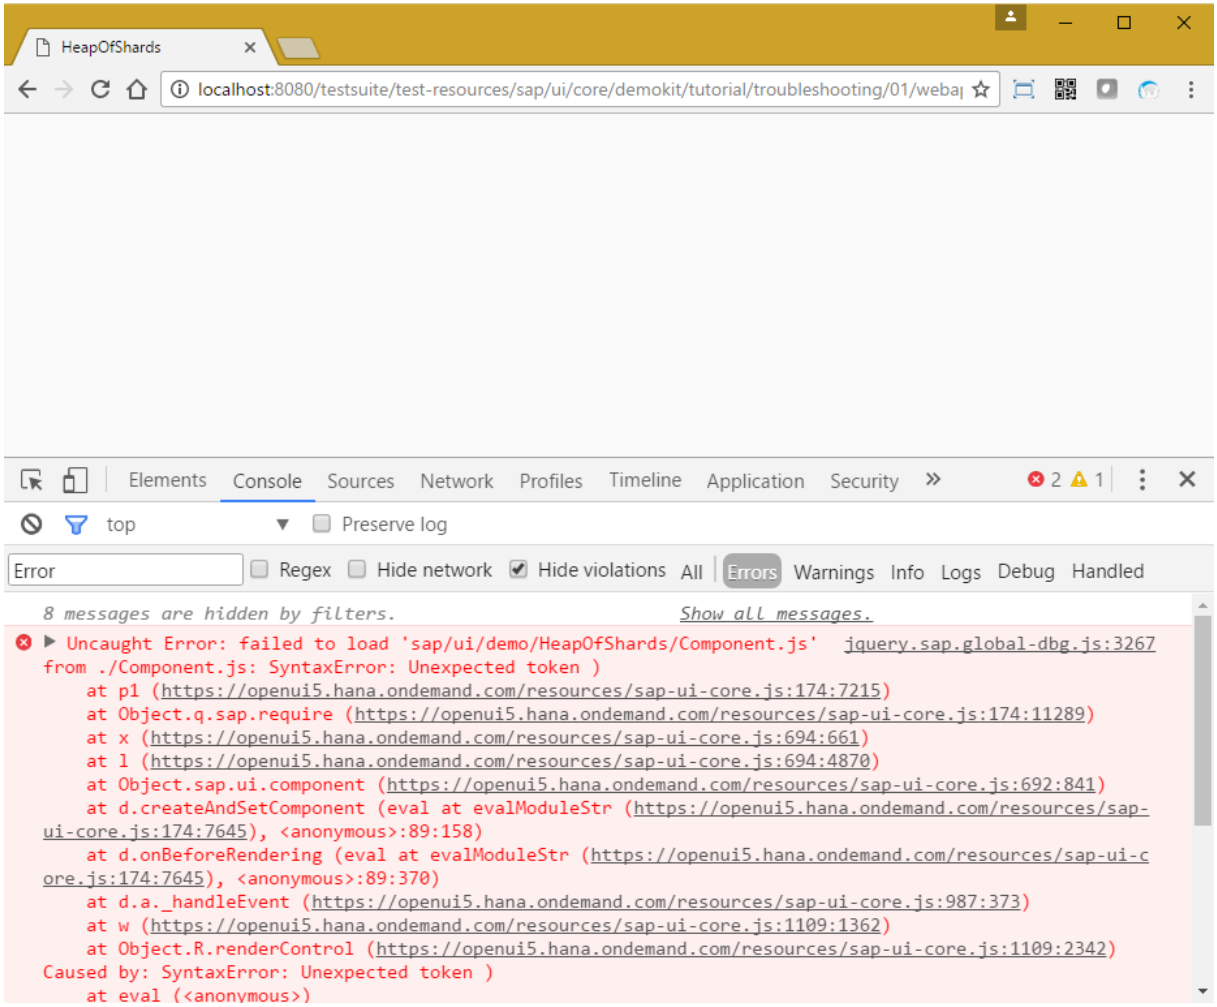


Figure 49: The browser displays an empty page and an `Uncaught Error` is issued in the console

Root Cause

This can happen for one of the following reasons:

- A critical reference error is prohibiting the app from starting.
- A syntax error is stopping the execution of your application code.
- A parsing error has occurred in an XML view.
- The tag of the control is written with lowercase letters.
- The root view is missing a root control.

Resolution

Console shows `"ReferenceError: sap is not defined"`

Have a look at the `resource` path in the bootstrap of the HTML page you are trying to open. The path to the file `sap-ui-core.js` is probably incorrect and needs to point to the path where the SAPUI5 resources are located (typically globally under `/resources` or locally under `resources`).

If you are running the code in SAP Web IDE, you have to configure the `neo-app.json` project descriptor (see Create a neo-app.json Project Configuration File [page 46]).

Other development environments might need the resources to be copied to the server and referenced relatively to the app (see Standard Variant for Bootstrapping [page 694]).

Alternatively, you can use the CDN version (see Variant for Bootstrapping from Content Delivery Network [page 696]).

Console shows `SyntaxError: <error details>`

A JavaScript error in the application code throws an exception and stops all subsequent execution. Take a look at the error details: In most cases, the root cause is mentioned in the first line of the error message.

The stack trace can provide more context on the execution scope. Analyze it from thoroughly to find a line referencing your application code and start debugging there.

Console shows `Error: Invalid XML`

If the XML view to be displayed cannot be parsed, SAPUI5 stops the execution and throws a parse error. Check the XML view for namespace issues, typos, and missing closing tags. Do a schema validation with an XML validator tool.

Console shows `Uncaught Error: failed to load 'sap/m/xxxxx.js'`

During the development on Microsoft Windows, your app works fine, but a soon as you deploy it on a Linux system, only an empty page comes up.

This could happen if you wrote the tag of the control with lowercase letters, because Linux systems use case-sensitive file names.

Correct Example	Incorrect Example
`<Button text="Click me" />`	`<button text="Click me" />` Error message: `Uncaught Error: failed to load 'sap/m/button.js'`

> → Tip
>
> Control tags always start with capital letters after the namespace like `<Button>`, `<l:FixFlex>`, `<f:SimpleForm>`.
>
> Aggregations always start with lowercase letters like `<content>`, `<l:fixContent>`, `<f:content>`

Console shows no error

Your root view is missing a root control. In the context of SAPUI5, `sap.m.App` or `sap.m.SplitApp` function as root controls. Please check your root view (for example `App.view.xml`) and add the missing root control.

Content or Control Is Not Visible

You find yourself in the situation that a control or the content of a control is not visible, but you don't see an error message in the console.

Root Cause

This can happen for one of the following reasons:

- The element is not properly bound
- The `visible` property is set to `false`
- The `height` or `width` dimension is set to `0`

Resolution

First, you should check if your control was rendered properly by using the developer tool of your browser to check the DOM element. For information about how to use your browser tools, see the documentation of you browser or check our Troubleshooting Tutorial Step 1: Browser Developer Tools [page 196].

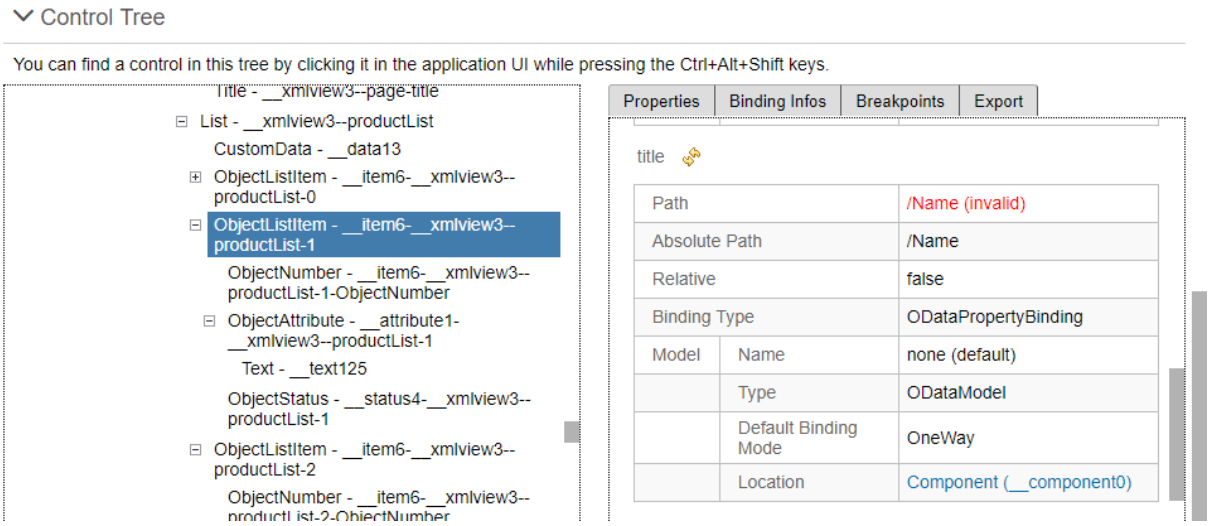
Wrong binding

If you bound your control to a source, for example, an image control, the binding may not be resolved properly. This can be caused by minor mistakes such as typos. We recommend using *Diagnostics* to debug your bindings. For more information, see Diagnostics [page 1326].

In the *Diagnostics* window, you can check whether you used a relative binding instead of an absolute one or vice versa.

If you, for example, use a `List` control, you bind the list itself to an absolute path like `items="{/Products}"` whereas the aggregations are bound to a relative path like `title="{Name}"`. The actual path of the `title` property is now `{/Products/*Product_Index*/Name}`.

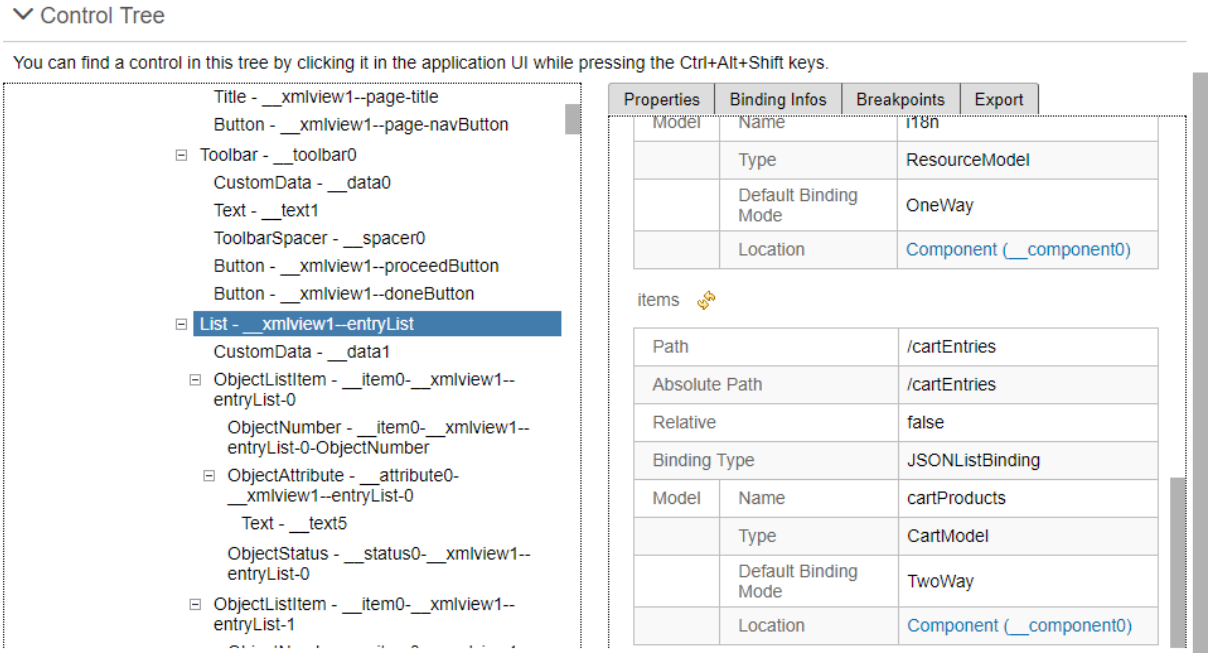
If you used an absolute binding path like `title="{/Name}` for an aggregation instead of a relative one, the result in the window would look like this:



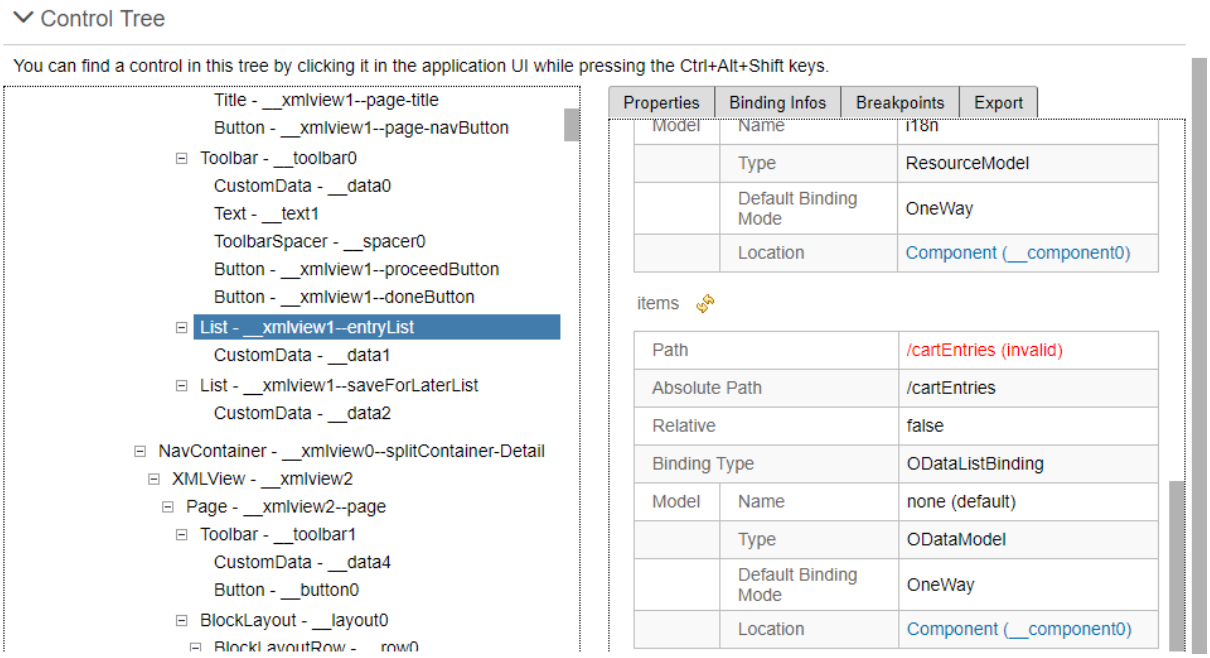
Another common error related to binding is to refer to the default model instead of referring to a specific model. This happens, for examples, if you forgot to add the model name to the binding declaration.

For example, you have two models in your application: the default model, which has no name and another model named `cartProducts`. To bind to the `cartProducts` model you have to write the model name explicitly like `items="{cartProducts>/cartEntries}"`.

If you used the binding correctly *Diagnostics* displays the following:



If the model name is missing, you see the following:



`visible` property set to `false`

If you set the `visible` property of a control to `false`, it will not be rendered at all.

Nested controls inherit the value of the `visible` property from their parents. Therefore, if the control that you are missing is nested in a parent control that is set to invisible, the nested control will also not be rendered.

You can fix this by setting the `visible` property of the parent control to `true` or by moving your missing control in the XML view so that it is not longer nested inside an invisible control.

Dimensions set to `0`

Most controls have the properties `width` and `height`. If one of them is explicitly set to `0` some controls may not be displayed at all. Similar to the `visible` property, the value of `width` and `height` are also inherited from parent controls, as long as you don't set an explicit value for these dimensions. If you, for example, set one of the dimension values for a control to `100%` it will have the same size as the parent control. And if the parent's width is `0` the nested control will also be `0`.

As with the `visible` property, you can solve this by either increasing the size of the parent or setting fixed values for the child (for example, `100px`) instead of a relative value.

Request Fails Due to Same-Origin Policy (Cross-Origin Resource Sharing - CORS)

If you use a remote URL in your code, for example a remote OData service, such as the publicly available Northwind OData service, the browser may refuse to connect to a remote URL. Due to the same-origin policy, browsers deny AJAX requests to service endpoints in case the service endpoint has a different domain/ subdomain, protocol, or port than the app.

Preview

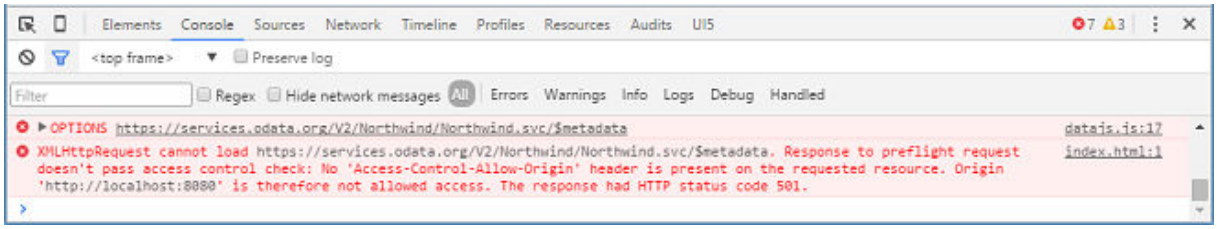


Figure 50: Violations of the same-origin policy in Google Chrome

Root Cause

Normally, the remote system would be configured to send the cross-origin resource sharing (CORS) headers to make the browser also allow direct access to remote URLs. However, if you, for example, use a Northwind OData service, you cannot modify the publicly available service. Then when you try to execute XHR requests (`XMLHttpRequest`) the browser prevents the call due to the same-origin policy.

Resolution

To solve the issue, you have the following options:

- SAP Web IDE: Configure a destination as described below (recommended)
- Local Development: Configure a local proxy (CORS anywhere)
- Workaround: Disable the same-origin policy in the browser for local testing (not recommended, only for testing)
- Set the CORS-relevant response headers on the remote system (if possible)

SAP Web IDE: Configure a destination

SAP Web IDE and the SAP Cloud Platform offer destinations that allow you to easily connect to remote systems. The destination to the Northwind OData service is an internet proxy made available inside the app at `<protocol>://<domain>/destinations/northwind/*`. Any request that is sent to this location is forwarded to `https://services.odata.org` automatically.

Create Destination in SAP Cloud Platform Cockpit

Requested URL	Forwarded To
`/destinations/northwind/V2/Northwind/Northwind.svc/$metadata`	`https://services.odata.org/V2/Northwind/Northwind.svc/$metadata`

Requested URL	Forwarded To
`/destinations/northwind/V2/Northwind/Northwind.svc/Invoices`	`https://services.odata.org/V2/Northwind/Northwind.svc/Invoices`

The destination itself is configured inside the SAP Cloud Platform Cockpit. For more information, see Create a Northwind Destination [page 49].

neo-app.json

For SAP Web IDE, a `neo-app.json` file is needed to make sure that the destination and resource mapping are available in the app. It has to be located in the root folder (`webapp`), on the same level as the `user.project.json` file that is automatically created.

If it does not exist yet, create a `neo-app.json` file and reference the Northwind destination there. Just copy the content of the code into that file and try to run the app again.

```
{
  "routes": [
    {
      "path": "/destinations/northwind",
      "target": {
        "type": "destination",
        "name": "northwind"
      },
      "description": "Northwind OData Service"
    }
  ]
}
```

> **i** Note
>
> If the file already exists, for example, because you already created it to map the SAPUI5 resources, just append the destination to the existing `route` definitions.

manifest.json

In the `manifest.json` descriptor file of your app, you can now change the data source to use the remote destination, for example:

```
{
  "_version": "1.12.0",
  "sap.app": {
    ...
    "dataSources": {
      "invoiceRemote": {
        "uri": "/destinations/northwind/V2/Northwind/Northwind.svc/",
        "type": "OData",
        "settings": {
          "odataVersion": "2.0"
        }
      }
    }
  },
  "sap.ui": {
    ...
  },
  "sap.ui5": {
    ...
```

```
    }
}
```

After this change, you can run the app in SAP Web IDE without disabling the same-origin policy of your browser. The destination now manages the connection to the remote service.

Local Development: Configure a local proxy (CORS anywhere)

A proxy is simply a service end point on the same domain of your app to overcome the restrictions. It receives requests from the app, forwards them to another server, and finally returns the corresponding response from the remote service.

Follow the below steps to configure such a proxy in your poject.

Prerequisites: NodeJS is installed on your machine.

package.json

```
{
    "name": "Sample-Package",
    "version": "1.0.0",
    "description": "Sample package.json",
    "scripts": {
        "proxy": "node proxy.js"
    },
    "devDependencies": {
        "cors-anywhere": "^0.4.1"
    },
    "dependencies": {
    }
}
```

Add the `devDependency` called `"cors-anywhere": "^0.4.1"` to your existing `package.json`. Run `node install` to install the npm module. Add the `proxy` script to the `scripts` section in the `package.json` so that you can run a script via `npm run <script_name>`.

proxy.js (new)

```
var cors_proxy = require('cors-anywhere');

// Listen on a specific IP Address
var host = 'localhost';

// Listen on a specific port, adjust if necessary
var port = 8081;

cors_proxy.createServer({
    originWhitelist: [], // Allow all origins
    requireHeader: ['origin', 'x-requested-with'],
    removeHeaders: ['cookie', 'cookie2']
}).listen(port, host, function() {
    console.log('Running CORS Anywhere on ' + host + ':' + port);
});
```

Create a new file `proxy.js`, and copy the above script into your project directory. This is the pre-configured proxy server we are going to use to prevent the occurrence of **same-origin policy error**. We can start it by running the command `node proxy.js` or `npm run proxy. It runs a local proxy on port` in the console.

manifest.json

```
{
    "sap.app": {
        ...
        "dataSources": {
            "northwind": {
                "uri": "http://localhost:8081/https://services.odata.org/V2/
Northwind/Northwind.svc/",
                "type": "OData",
                "settings": {
                    "odataVersion": "2.0"
                }
            }
        }
    }
}
```

To use a service in the `local ui5 application` we have to change the `uri` in the `manifest` file.

> **i** Note
>
> The `uri` must start with `http://localhost:<port>`.

> **i** Note
>
> By default, you can't run the request in your browser with the `proxy.js` script. It throws the following exception: `exception Missing required request header. Must specify one of: origin,x-requested-with`. If you want to test the service in your browser, you can temporarily comment out the line `requireHeader: ['origin', 'x-requested-with']` from your `proxy.js`.

For more information on CORS Anywhere, see https://www.npmjs.com/package/cors-anywhere

Workaround: Disable the same-origin policy in the browser (not recommended, only for testing)

. It runs a local proxyIn Google Chrome, you can easily disable the same-origin policy of Chrome by running Chrome with the following command: `[your-path-to-chrome-installation-dir]\chrome.exe --disable-web-security --user-data-dir`. Make sure that all instances of Chrome are closed before you run the command. This allows all web sites to break out of the same-origin policy and connect to the remote service directly.

> ⚠ Caution
>
> **This approach is not recommended for productive apps. Running Chrome this way for surfing on the internet poses a security risk.** However, it allows you to avoid the need of setting up a proxy at development time or for testing purposes.

App or Control Looks Odd

You find yourself in a situation that your app or a control looks different than you expected.

Root Cause

This can happen for one of the following reasons:

- An HTML file is missing the `DOCTYPE` specification (this leads, for example, to exceptionally high table headers)
- Custom styles aren't working properly
- The theme you are using does not support the used libraries

Resolution

To solve the issue, you have the following options:

- Check whether the `<!DOCTYPE html>` tag is placed at the beginning of each HTML file, before the `<html>` tag.
- Check if you have used a custom CSS in your app.
  If you have used a custom CSS, it is probably interfering with the styling in the standard SAPUI5 theming libraries.
  Use the developer tools of your browser to inspect the element that has the wrong styling. In the HTML tab, you can usually see which styles are applied to a DOM element. If you have styles in the list that are added by your app, disable these styles in the debugger to see whether this solves the problem.

  > **i Note**
  >
  > SAPUI5-specific CSS classes and IDs all have an `sapUi` prefix, for example, `sapUiButton`.

  If this does not solve the issue, check for inline styles that are applied to the element in the HTML code. You can also try to isolate the control from the app to see whether there is an issue with the control instead of a collision of styles.
- Check whether the theme you that you are using is supported in combination with the libraries that you are using in your app. For more information, see Supported Combinations of Themes and Libraries [page 27] and Deprecated Themes and Libraries [page 34].

Data Binding

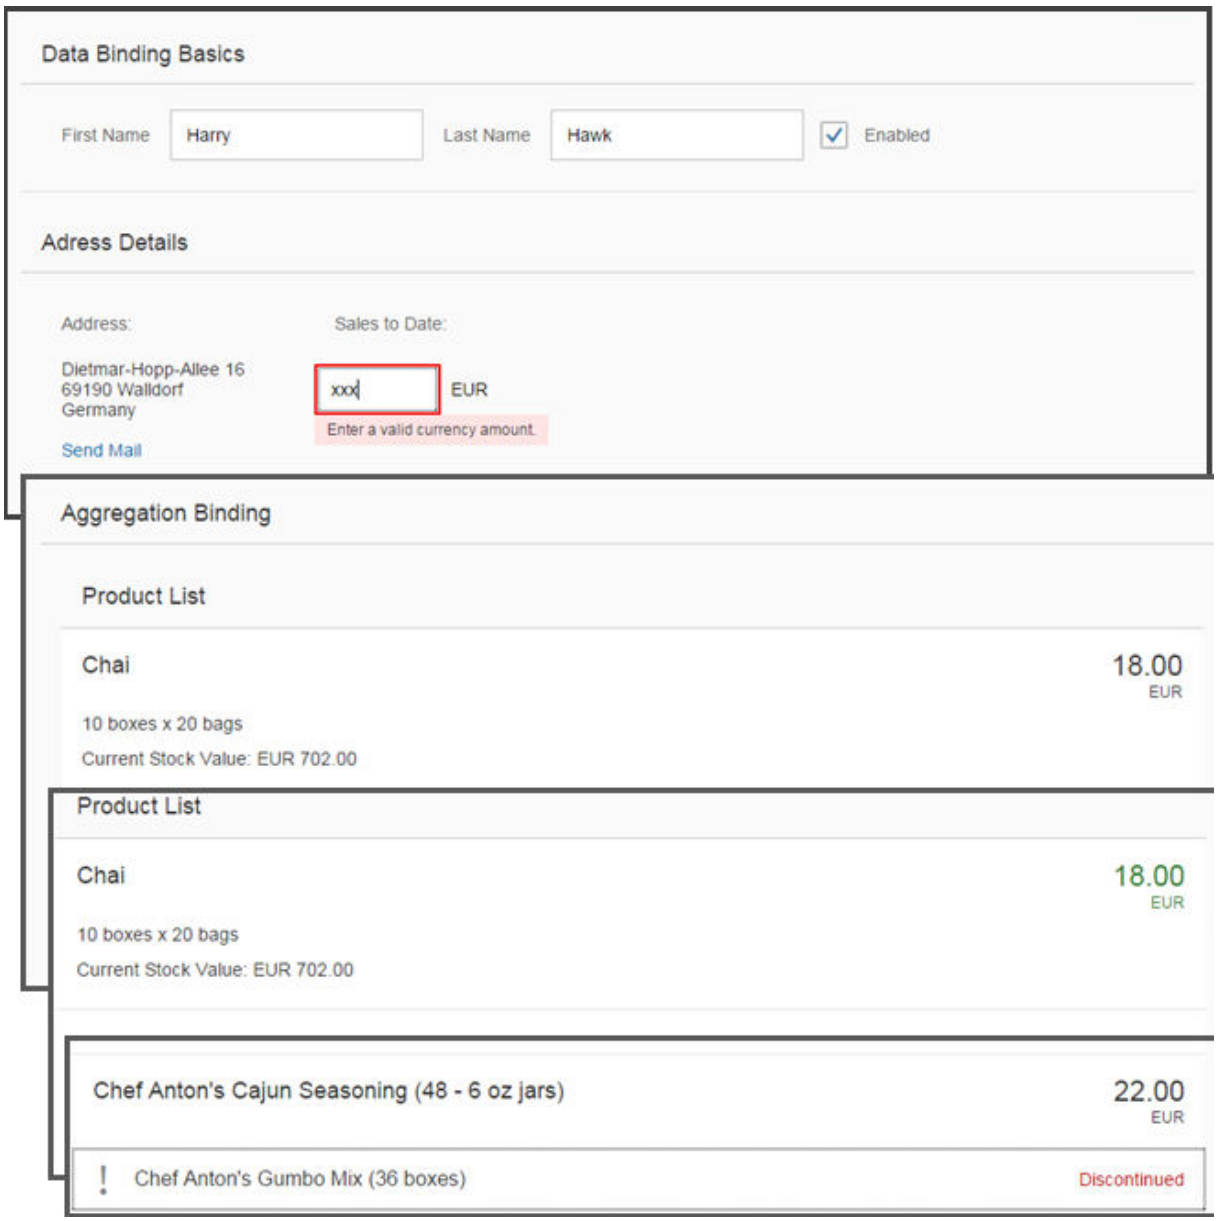
In this tutorial, we will explain the concepts of data binding in SAPUI5.

You use data binding to bind UI elements to data sources to keep the data in sync and allow data editing on the UI.

For data binding, you need a model and a binding instance: The model instance holds the data and provides methods to set the data or to retrieve the data from a server. It also provides a method for creating bindings to the data. When this method is called, a binding instance is created, which contains the binding information and provides an event, which is fired whenever the bound data changes. An element can listen to this event and update its visualization according to the new data.

The UI uses data binding to bind controls to the model which holds the application data, so that the controls are updated automatically whenever application data changes. Data binding is also used the other way round, when changes in the control cause updates in the underlying application data, for example data entered by the user. This is called two-way binding.

Preview



→ Tip

You don't have to do all tutorial steps sequentially, you can also jump directly to any step you want. Just download the code from the previous step, copy it to your workspace and make sure that the application runs by calling the `webapp/index.html` file.

You can view and download the files for all steps in the Demo Kit at Data Binding. Depending on your development environment you might have to adjust resource paths and configuration entries.

For more information check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]

Related Information

Data Binding [page 815]
Model View Controller (MVC) [page 784]

Step 1: No Data Binding

In this step, we simply place some text on the screen using a standard `sap.m.Text` control. The text in this control is a hard-coded part of the control's definition; therefore, this is not an example of data binding!

Preview

Figure 51: Screen with text

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 1.

webapp/index.html (New)

```
<!DOCTYPE HTML>
<html>
<head>
    <meta charset="utf-8">
    <meta name="viewport" content="width=device-width, initial-scale=1.0">
    <title>Data Binding</title>
    <script id="sap-ui-bootstrap"
        src="resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-libs="sap.m"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true">
    </script>
    <script src="index.js"></script>
</head>
<body class="sapUiBody" id="content"></body>
</html>
```

Create a new folder `webapp` which will contain all sources of the app that we will create throughout this tutorial, and create the `index.html` file within this folder.

webapp/index.js (New)

```
sap.ui.require([
    "sap/m/Text"
], function (Text) {
    "use strict";
    // Attach an anonymous function to the SAPUI5 'init' event
    sap.ui.getCore().attachInit(function () {
        // Create a text UI element that displays a hardcoded text string
        new Text({text: "Hi, my name is Harry Hawk"}).placeAt("content");
    });
});
```

Create a new `index.js` file that will contain the application logic for this tutorial. We start by placing the `sap.m.Text` control into the html content. Since the value of the control's text property has been hard-coded, it is unrelated to any data that might exist within a model object. Therefore, data binding is **not** being used here.

Step 2: Creating a Model

In this step, we create a model as container for the data on which your application operates.

The business data within a model can be defined using various formats:

- JavaScript Object Notation (JSON)
- Extensible Markup Language (XML)
- OData
- Your own custom format (not covered in this tutorial)

> **i Note**
>
> There is also a special type of model called a "resource model". This model type is used as a wrapper object around a resource bundle file. The names of such files must end with `.properties` and are used typically for holding language-specific text.
>
> We will use this in Step 6: Resource Models [page 229].

When JSON, XML and resource models are created, the data they contain is loaded in a single request (either from a file stored locally on the client or by requesting it from a Web server). In other words, after the model's data has been requested, the entire model is known to the application. These models are known as client-side models and tasks such as filtering and sorting are performed locally on the client.

An OData model however, is a server-side model. This means that whenever an application needs data from the model, it must be requested from the server. Such a request will almost never return all the data in the model, typically because this would be far more data than is required by the client application. Consequently, tasks such as sorting and filtering should always be delegated to the server.

In this tutorial, we will focus on JSON models since they are the simplest ones to work with.

Preview

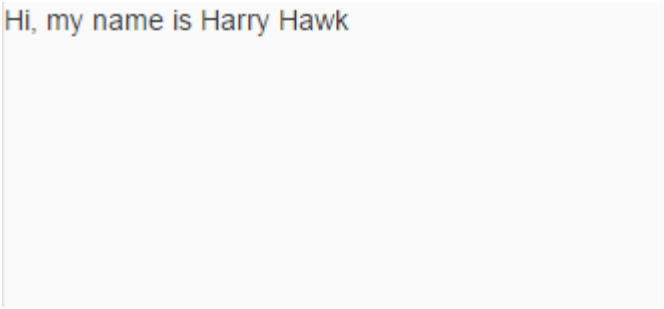


Figure 52: Screen with text derived from a model object (No visual changes to last step)

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 2.

webapp/index.js

```
sap.ui.require([
    "sap/m/Text",
    "sap/ui/model/json/JSONModel"
], function (Text, JSONModel) {
    "use strict";
    // Attach an anonymous function to the SAPUI5 'init' event
    sap.ui.getCore().attachInit(function () {
        // Create a JSON model from an object literal
        var oModel = new JSONModel({
```

```
            greetingText: "Hi, my name is Harry Hawk"
        });

        // Assign the model object to the SAPUI5 core
        sap.ui.getCore().setModel(oModel);
        // Create a text UI element that displays a hardcoded text string
        new Text({text: "Hi, my name is Harry Hawk"}).placeAt("content");
    });
});
```

Create a new JSON model passing the data as object literal and store the resulting model instance in a local variable called `oModel`.

Set `oModel` to be the default model within the entire SAPUI5 core.

This makes the model object globally available to all controls used within the application.

In this case we have bound the model object to the SAPUI5 core. This has been done for simplicity, but is not considered good practice. Generally speaking, a model object holding business data should be bound to the view that displays the data. We will correct this part of the code in the following steps.

> **i** Note
>
> Models can be set on every control by calling `setModel()`. The model is then propagated to all aggregated child controls (and their children, and so on...). All child control will then have access to that model

The text that is displayed on the UI is still hard-coded and not taken from the model - we will bind the property `greetingText` to our UI control in the next step.

Related Information

Models [page 882]
JSON Model [page 991]

Step 3: Create Property Binding

Although there is no visible difference, the text on the screen is now derived from model data.

Preview

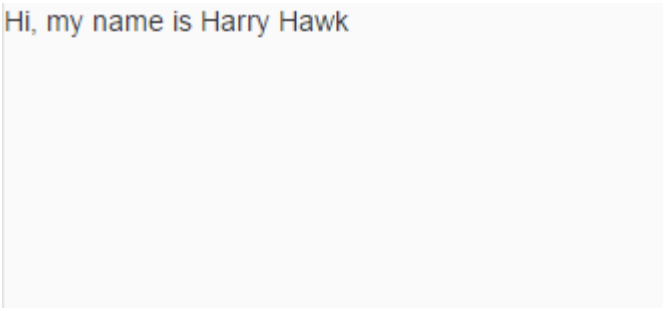

Figure 53: Screen with text derived from various sources (No visual changes to last step)

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 3.

webapp/index.js

```
sap.ui.require([
    "sap/m/Text",
    "sap/ui/model/json/JSONModel"
], function (Text, JSONModel) {
    "use strict";
    // Attach an anonymous function to the SAPUI5 'init' event
    sap.ui.getCore().attachInit(function () {
        // Create a JSON model from an object literal
        var oModel = new JSONModel({
            greetingText: "Hi, my name is Harry Hawk"
        });
        // Assign the model object to the SAPUI5 core
        sap.ui.getCore().setModel(oModel);
        // Display a text element whose text is derived
        // from the model object
        new Text({text: "{/greetingText}"}).placeAt("content");
    });
});
```

The `text` property of the `sap.m.Text` control is set to the value `{/greetingText}`. The curly brackets enclosing a binding path (binding syntax) are automatically interpreted as a binding. These binding instances are called `PropertyBindings`. In this case, the control's `text` property is bound to the `greetingText` property at the root of the default model, as the slash (`/`) at the beginning of the binding path denotes an absolute binding path.

Related Information

Binding Types [page 817]
Property Binding [page 818]

Step 4: Two-Way Data Binding

In the examples used so far, we have used a read-only field to display the value of a model property. We will now change the user interface so that the first and last name fields are displayed using `sap.m.Input` fields and an additional check box control is used to enable or disable both input fields. This arrangement illustrates a feature known as "two-way data binding". Now that the view contains more controls, we will also move the view definition into an XML file.

Preview

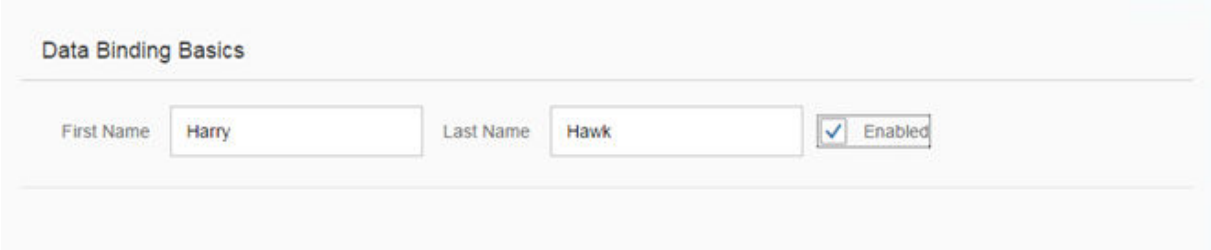

Figure 54: Input fields can be enabled or disabled

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 4.

webapp/view/App.view.xml (New)

```
<mvc:View xmlns="sap.m" xmlns:mvc="sap.ui.core.mvc">
  <Panel headerText="{/panelHeaderText}" class="sapUiResponsiveMargin"
width="auto">
    <content>
      <Label text="First Name" class="sapUiSmallMargin" />
      <Input value="{/firstName}" valueLiveUpdate="true" width="200px"
enabled="{/enabled}" />
      <Label text="Last Name" class="sapUiSmallMargin" />
      <Input value="{/lastName}" valueLiveUpdate="true" width="200px" enabled="{/
enabled}" />
      <CheckBox selected="{/enabled}" text="Enabled" />
    </content>
  </Panel>
</mvc:View>
```

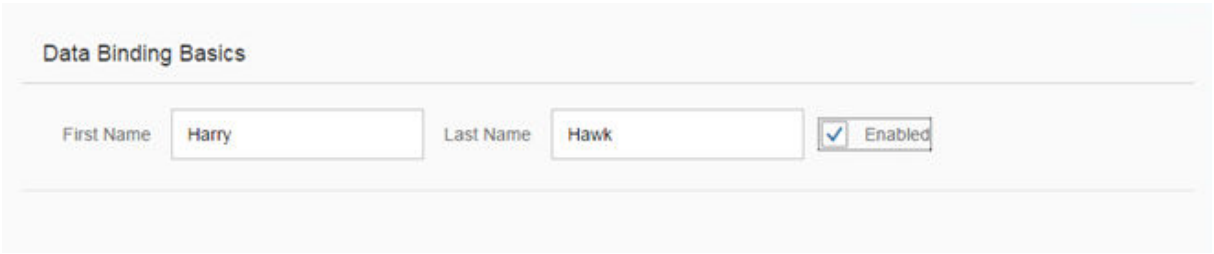
We create a new `view` folder in our app and a new file for our XML view inside the app folder.

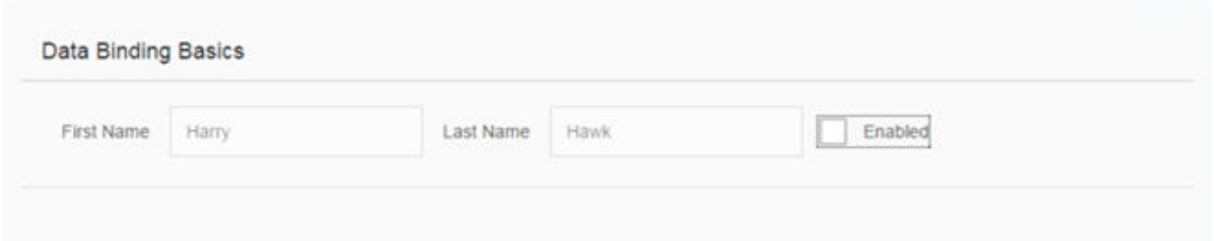
webapp/index.js

```
sap.ui.require([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/XMLView"
], function (JSONModel, XMLView) {
    "use strict";
    // Attach an anonymous function to the SAPUI5 'init' event
    sap.ui.getCore().attachInit(function () {
        // Create a JSON model from an object literal
        var oModel = new JSONModel({
            firstName: "Harry",
            lastName: "Hawk",
            enabled: true,
            panelHeaderText: "Data Binding Basics"
        });
        // Assign the model object to the SAPUI5 core
        sap.ui.getCore().setModel(oModel);
        // Display the XML view called "App"
        new XMLView({
            viewName: "sap.ui.demo.db.view.App"
        }).placeAt("content");
    });
});
```

We delete the code that assigned the `sap.m.Text` field to the UI and add an XML view that is identified by its resource name.

You can now refresh the application preview and select or deselect the checkbox. You will see that the input fields are automatically enabled or disabled in response to the state of the checkbox.





It is clear that we have not written any code to transfer data between the user interface and the model, yet the `Input` controls are enabled or disabled according to the state of the checkbox. This behaviour is the result of the fact that all SAPUI5 models implement two-way data binding, and for JSON Models, two-way binding is the default behavior.

Two things are happening here:

- Data binding allows the property of a control to derive its value from any suitable property in a model.
- SAPUI5 automatically handles the transport of data both from the model to the controls, and back from the controls to the model. This is called two-way binding.

Related Information

Data Binding [page 815]

Step 5: One-Way Data Binding

In contrast to the two-way binding behavior shown above, one-way data binding is also possible. Here, data is transported in one direction only: from the model, through the binding instance to the consumer (usually the property of a control), but never in the other direction. In this example, we will change the previous example to use one-way data binding. This will illustrate how the flow of data from the user interface back to the model can be switched off if required.

Preview

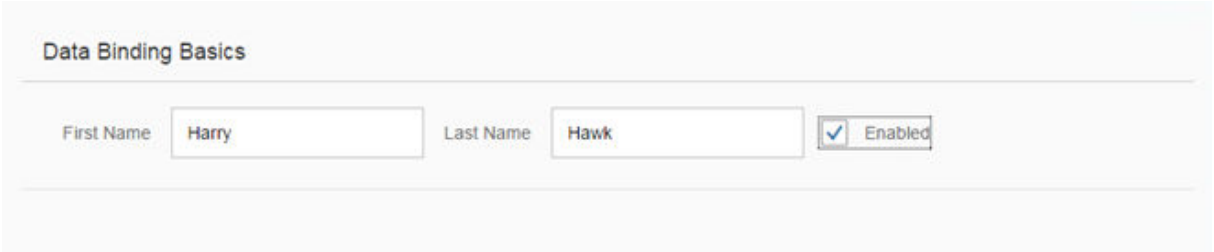


Figure 55: Two-way data binding disabled for the checkbox

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 5.

webapp/index.js

```
sap.ui.require([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/XMLView",
    "sap/ui/model/BindingMode"
], function (JSONModel, XMLView, BindingMode) {
    "use strict";
    // Attach an anonymous function to the SAPUI5 'init' event
```

```
    sap.ui.getCore().attachInit(function () {
        // Create a JSON model from an object literal
        var oModel = new JSONModel({
            firstName: "Harry",
            lastName: "Hawk",
            enabled: true,
            panelHeaderText: "Data Binding Basics"
        });
        oModel.setDefaultBindingMode(BindingMode.OneWay);

tml
        // Assign the model object to the SAPUI5 core
        sap.ui.getCore().setModel(oModel);
        // Display the XML view called "App"
        new XMLView({
            viewName: "sap.ui.demo.db.view.App"
        }).placeAt("content");
    });
});
```

Insert the single highlighted line immediately after the creation of the model object in `index.js`.

Now, no matter what state the checkbox is in, the input fields remain open for input because one-way data binding ensures that data flows only from the model to the UI, but never in the other direction.

The binding mode (one-way or two-way) is set on the model itself. Therefore, unless you specifically alter it, a binding instance will always be created using the model's default binding mode.

Should you wish to alter the binding mode, then there are two ways of doing this:

- Alter the model's default binding mode. This is the approach used above.
- Specify the data binding mode for a specific binding instance by using the `oBindingInfo.mode` parameter. This change applies only to this data binding instance. Any other binding instances will continue to use the model's default binding mode. For more information, see API Reference: `sap.ui.base.ManagedObject.bindProperty`.

> **i Note**
>
> There are two important points to understand about alterations to a model object's data binding mode:
>
> - If you alter the default binding mode of a model (as in the example above), then unless you explicitly say otherwise, all binding instances created after that point in time will use the altered binding mode.
> - Altering a model's default binding mode has no effect on already existing binding instances.

Step 6: Resource Models

Business applications also require language-specific (translatable) texts used as labels and descriptions on the user interface.

The example we used at the start of this tutorial was overly simplistic as we stored language-specific text directly in a JSON model object. Generally speaking, unless language-specific text is derived directly from a back-end system, it is not considered good programming practice to place translatable texts directly into a model. So let's correct this situation by placing all translatable texts (such as field labels) into a resource bundle.

Preview

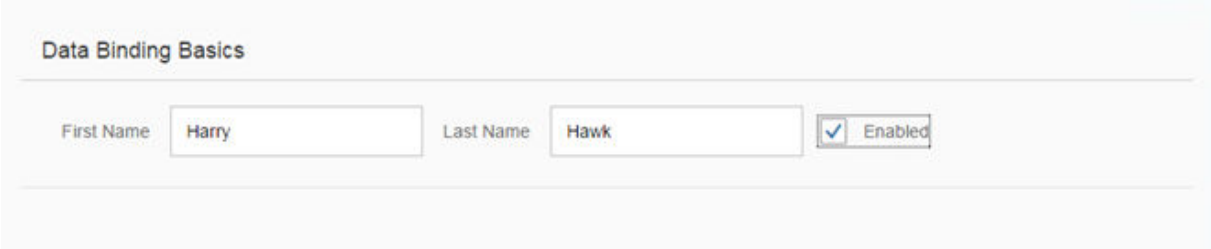

Figure 56: Texts derived from the resource model (No visual change to last step)

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 6.

webapp/index.js

```
sap.ui.require([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/XMLView",
    "sap/ui/model/resource/ResourceModel"
], function (JSONModel, XMLView, ResourceModel) {
    "use strict";
    // Attach an anonymous function to the SAPUI5 'init' event
    sap.ui.getCore().attachInit(function () {
        // Create a JSON model from an object literal
        var oModel = new JSONModel({
            firstName: "Harry",
            lastName: "Hawk",
            enabled: true
        });
        // Assign the model object to the SAPUI5 core
        sap.ui.getCore().setModel(oModel);
        // Create a resource bundle for language specific texts
        var oResourceModel = new ResourceModel({
            bundleName: "sap.ui.demo.db.i18n.i18n"
        });

        // Assign the model object to the SAPUI5 core using the name "i18n"
        sap.ui.getCore().setModel(oResourceModel, "i18n");
        // Display the XML view called "App"
        new XMLView({
            viewName: "sap.ui.demo.db.view.App"
        }).placeAt("content");
    });
});
```

Since we are creating a resource model, the file name is assumed to have the extension `.properties`; this does not need to be stated explicitly. The resource model is set to the core using the model name `i18n`.

> **i** Note
>
> Remove `, panelHeaderText : "Data Binding Basics"` from the model definition in the `index.js` file. This text is now moved to the resource model.

webapp/i18n/i18n.properties (New)

```
# Field labels
firstName=First Name
lastName=Last Name
enabled=Enabled

# Screen titles
panelHeaderText=Data Binding Basics
```

Create a new folder `i18n`, and a new file `i18n.properties` within and add the code above.

The `panelHeaderText` property has been moved from the JSON model into the `i18n` resource bundle, also the field labels are no longer hard coded in the XML view. This is because all of these text fields need to be translated.

Language-specific text stored in resource models obeys the Java convention for internationalization (i18n).

webapp/view/App.view.xml

```
<mvc:View
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Panel headerText="{i18n>panelHeaderText}" class="sapUiResponsiveMargin"
width="auto">
        <content>
            <Label text="{i18n>firstName}" class="sapUiSmallMargin"/>
            <Input value="{/firstName}" valueLiveUpdate="true" width="200px"
enabled="{/enabled}"/>
            <Label text="{i18n>lastName}" class="sapUiSmallMargin"/>
            <Input value="{/lastName}" valueLiveUpdate="true" width="200px"
enabled="{/enabled}"/>
            <CheckBox selected="{/enabled}" text="{i18n>enabled}"/>
        </content>
    </Panel>
</mvc:View>
```

Modify the data binding for the panel header and the labels in `App.view.xml` to include the model name. Notice that a "greater than" character separates the model name and the property name, and that i18n property names **must not** start with a slash character.

You could use multiple model instances by using different model names. The model name could be set as second parameter using the `setModel(oResourceModel,"i18n")` method. The model is then propagated under this name to all aggregated child controls (and their children, and so on...). All these controls have access to this model under the name `i18n` as well as to the `JSONModel` (default model, which has no name).

Related Information

Resource Model [page 995]

Step 7: (Optional) Resource Bundles and Multiple Languages

The reason we have resource bundles is to allow an app to run in multiple languages without the need to change any code. To demonstrate this feature, we will create a German version of the app – in fact all we need to do is create a German version of the resource bundle file. No code changes are needed.

Preview

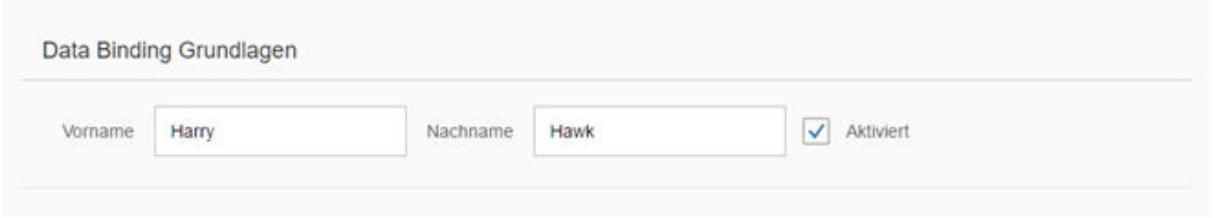

Figure 57: German version of our UI

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 7.

webapp/i18n/i18n_de.properties (New)

```
# Field labels
firstName=Vorname
lastName=Nachname
enabled=Aktiviert
# Screen titles
panelHeaderText=Data Binding Grundlagen
```

In the `i18n` folder, take a copy of the file `i18n.properties` and call it `i18n_de.properties`. Change the English text to the German text.

To test the outcome, change the default language of your browser to German and refresh your preview.

Related Information

Localization [page 1269]

Step 8: Binding Paths: Accessing Properties in Hierarchically Structured Models

In step 6 , we stated that the fields in a resource model are arranged in a flat structure; in other words, there can be no hierarchy of properties; however, this is true only for resource models. The properties within JSON and OData models almost always are arranged in a hierarchical structure. Therefore, we should take a look at how to reference fields in a hierarchically structured model object.

Preview

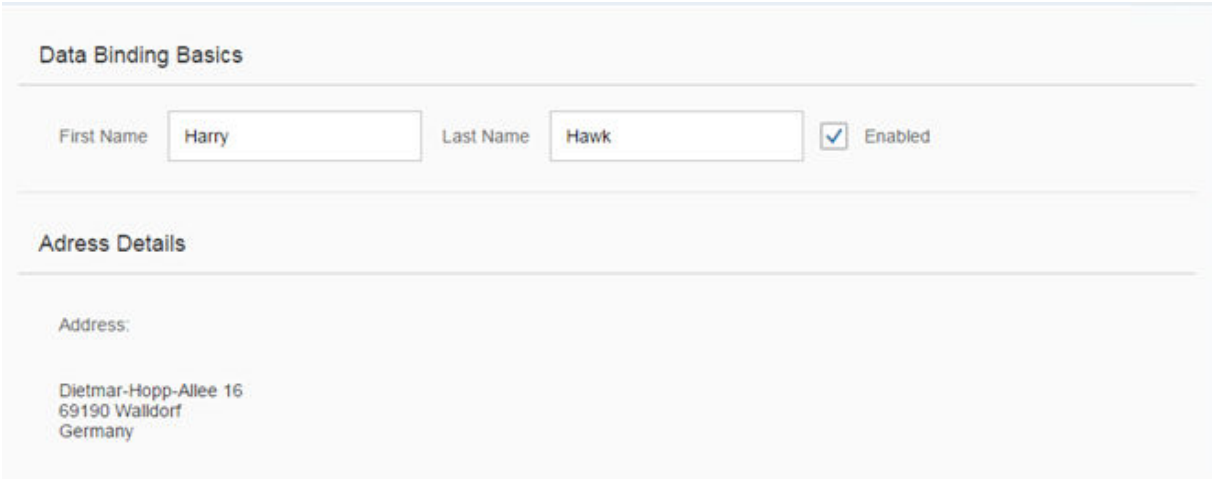

Figure 58: Second panel with additional data

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 8.

webapp/index.js

```
sap.ui.require([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/XMLView",
    "sap/ui/model/resource/ResourceModel"
], function (JSONModel, XMLView, ResourceModel) {
    "use strict";
    // Attach an anonymous function to the SAPUI5 'init' event
    sap.ui.getCore().attachInit(function () {
        var oModel = new JSONModel({
            firstName: "Harry",
            lastName: "Hawk",
            enabled: true,
            address: {
                street: "Dietmar-Hopp-Allee 16",
                city: "Walldorf",
```

```
                zip: "69190",
                country: "Germany"
            }
        });
        // Assign the model object to the SAPUI5 core
        sap.ui.getCore().setModel(oModel);
        var oResourceBundle = new ResourceModel({
            bundleName: "sap.ui.demo.db.i18n.i18n"
        });
        sap.ui.getCore().setModel(oResourceBundle, "i18n");
        // Display the XML view called "App"
        new XMLView({
            viewName: "sap.ui.demo.db.view.App"
        }).placeAt("content");
    });
});
```

The JSON model object now contains an additional sub-object called `address`. Within this object are four properties: `street`, `city`, `zip`, and `country`.

webapp/view/App.view.xml

```
<mvc:View
    xmlns="sap.m"
    xmlns:l="sap.ui.layout"
    xmlns:mvc="sap.ui.core.mvc">
    <Panel headerText="{i18n>panel1HeaderText}" class="sapUiResponsiveMargin"
width="auto">
        <content>
            <Label text="{i18n>firstName}" class="sapUiSmallMargin"/>
            <Input value="{/firstName}" valueLiveUpdate="true" width="200px"
enabled="{/enabled}"/>
            <Label text="{i18n>lastName}" class="sapUiSmallMargin"/>
            <Input value="{/lastName}" valueLiveUpdate="true" width="200px"
enabled="{/enabled}"/>
            <CheckBox selected="{/enabled}" text="Enabled"/>
        </content>
    </Panel>
    <Panel headerText="{i18n>panel2HeaderText}" class="sapUiResponsiveMargin"
width="auto">
        <content>
            <l:VerticalLayout>
                <Label class="sapUiSmallMargin" text="{i18n>address}:"/>
                <FormattedText class="sapUiSmallMarginBegin
sapUiSmallMarginBottom" htmlText="{/address/street}&lt;br&gt;{/address/zip} {/
address/city}&lt;br&gt;{/address/country}" width="200px"/>
            </l:VerticalLayout>
        </content>
    </Panel>
</mvc:View>
```

We add a new panel to the XML view with a new `Label` and `Text` pair of elements.

The text property of the `Label` element is bound to the i18n resource bundle field `address`.

The text property of the `Text` element is bound to three i18n properties: `/address/street`, `/address/zip`, `/address/city`, and `/address/country`. The resulting address format is achieved by separating each one of these model property references with a hard-coded newline character while `zip` and `city` are separated by a space.

webapp/i18n/i18n.properties

```
# Field labels
firstName=First Name
lastName=Last Name
enabled=Enabled
address=Address
# Screen titles
panel1HeaderText=Data Binding Basics
panel2HeaderText=Address Details
```

webapp/i18n/i18n_de.properties

```
# Field labels
firstName=Vorname
lastName=Nachname
enabled=Aktiviert
address=Adresse
# Screen titles
panel1HeaderText=Data Binding Grundlagen
panel2HeaderText=Adressdetails
```

> **i** Note
>
> The resource bundle files now contain new properties for the **Address** and a new panel header text. Both panel properties have been numbered.
>
> In the XML view, inside the curly brackets for the binding path of the `Text` element, notice that the first character is a forward slash. This is required for binding paths that make absolute references to properties in JSON and OData models, but must not be used for resource models. After the first forward slash character, the binding path syntax uses the object names and the property name separated by forward slash characters (`{/address/street}`).
>
> As has been mentioned previously, all binding path names are case-sensitive.

Related Information

JSON Model [page 991]

Step 9: Formatting Values

We also want to provide our users a way of contacting Harry Hawk. Therefore we will add a link that sends an e-mail to Harry. To achieve that we will convert our data in the model to match the

`sap.m.URLHelper.normalizeEmail` API. As soon as the user changes the name, the e-mail will also change. We will need a custom formatter function for this.

Preview

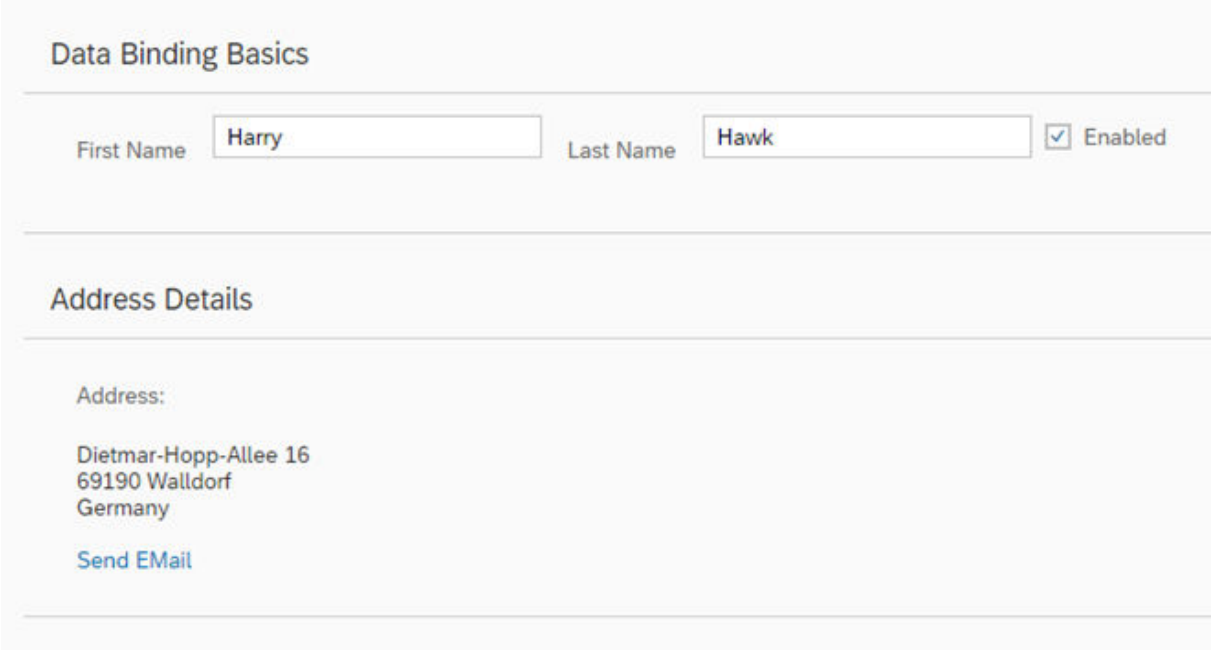

Figure 59: Address with e-mail link

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 9.

webapp/controller/App.controller.js (New)

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/library"
], function (Controller, mobileLibrary) {
    "use strict";

    return Controller.extend("sap.ui.demo.db.controller.App", {
        formatMail: function(sFirstName, sLastName) {
            var oBundle = this.getView().getModel("i18n").getResourceBundle();
            return mobileLibrary.URLHelper.normalizeEmail(
                sFirstName + "." + sLastName + "@example.com",
                oBundle.getText("mailSubject", [sFirstName]),
                oBundle.getText("mailBody"));
        }
    });
});
```

Create a new folder `controller` within your `webapp` folder as a general location for all controller files for this app and create a new file `App.controller.js`.

In our custom formatter, we define the first and last name that are currently in the model as function parameters. When a user changes the data in the model by entering a different name in the input fields, our formatter will be invoked automatically by the framework. This makes sure that the UI is in sync with the data model.

In the `formatMail` function, we use the `sap.m.URLHelper.normalizeEmail` function that expects an e-mail address, a mail subject and a text body. When a user chooses the link, the default email client will open with these parameters.For more information, see API Reference: `sap.m.URLHelper.normalizeEmail`. The `mailSubject` resource bundle text will contain a placeholder for the first name of the recipient (see below). Therefore, we provide the name with `[sFirstName]`.

> **i Note**
>
> For a detailed description of the e-mail link format, see https://developer.mozilla.org/de/docs/Web/Guide/HTML/Email_links .

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.db.controller.App"
    xmlns="sap.m"
    xmlns:l="sap.ui.layout"
    xmlns:mvc="sap.ui.core.mvc">
    <Panel headerText="{i18n>panel1HeaderText}" class="sapUiResponsiveMargin"
width="auto">
        <content>
            <Label text="{i18n>firstName}" class="sapUiSmallMargin"/>
            <Input value="{/firstName}" valueLiveUpdate="true" width="200px"
enabled="{/enabled}"/>
            <Label text="{i18n>lastName}" class="sapUiSmallMargin"/>
            <Input value="{/lastName}" valueLiveUpdate="true" width="200px"
enabled="{/enabled}"/>
            <CheckBox selected="{/enabled}" text="Enabled"/>
        </content>
    </Panel>
    <Panel headerText="{i18n>panel2HeaderText}" class="sapUiResponsiveMargin"
width="auto">
        <content>
            <l:VerticalLayout>
                <Label class="sapUiSmallMargin" text="{i18n>address}:"/>
                <FormattedText class="sapUiSmallMarginBegin
sapUiSmallMarginBottom" htmlText="{/address/street}&lt;br&gt;{/address/zip} {/
address/city}&lt;br&gt;{/address/country}" width="200px"/>
                <Link class="sapUiSmallMarginBegin"
                    href="{
                            parts: [
                                '/firstName',
                                '/lastName'
                            ],
                            formatter: '.formatMail'
                        }"
                    text="{i18n>sendEmail}"/>
            </l:VerticalLayout>
        </content>
    </Panel>
```

```
</mvc:View>
```

For more complex bindings we cannot use the simple binding syntax with the curly braces anymore. The `href` property of the `Link` element now contains an entire object inside the string value. In this case, the object has two properties:

- `parts`
  This is a JavaScript array in which each element is an object containing a `path` property. The number and order of the elements in this array corresponds directly to the number and order of parameters expected by the `formatMail` function.
- `formatter`
  A reference to the function that receives the parameters listed in the `parts` array. Whatever value is returned by the formatter function becomes the value set for this property. The dot (`formatMail`) at the beginning of the formatter tellsSAPUI5 to look for a `formatMail` function on the controller instance of the view. If you do not use the dot, the function will be resolved by looking into the global namespace.

> **i** Note

webapp/i18n/i18n.properties

```
…
# Screen titles
panel1HeaderText=Data Binding Basics
panel2HeaderText=Address Details
When using formatter functions, the binding is automatically switched to
                    "one-way". So you can’t use a formatter function for "two-
way" scenarios, but
                    you can use data types (which will be explained in the
following steps).# E-mail
sendEmail=Send Mail
mailSubject=Hi {0}!
mailBody=How are you?
```

webapp/i18n/i18n_de.properties

```
…
# Screen titles
panel1HeaderText=Data Binding Grundlagen
panel2HeaderText=Adressdetails
# E-mail
sendEmail=E-mail versenden
mailSubject=Hallo {0}!
mailBody=Wie geht es dir?
```

And we add the missing texts to the `properties` files

Step 10: Property Formatting Using Data Types

SAPUI5 provides a set of simple data types such as `Boolean`, `Currency`, `Date` and `Float`. These data types can then be applied to controls in order to ensure that the value presented on the screen is formatted correctly, and, if the field is open for input, that the value entered by the user adheres to the requirements of that data type. We will now add a new field called *Sales to Date* of type `Currency`.

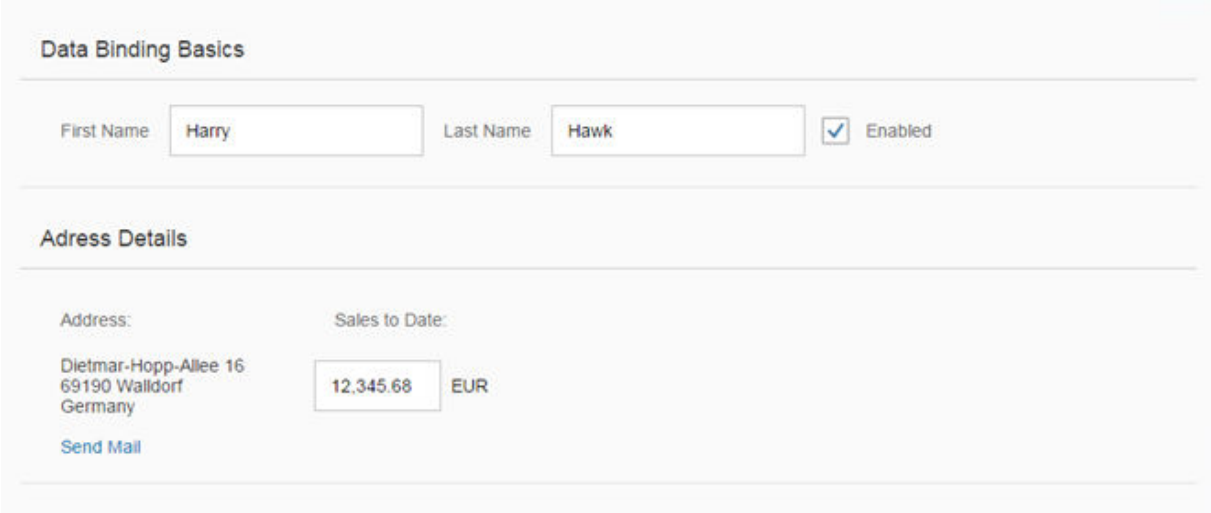

Figure 60: New *Sales to Date* input field

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 10.

webapp/index.js

```
sap.ui.require([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/XMLView",
    "sap/ui/model/resource/ResourceModel"
], function (JSONModel, XMLView, ResourceModel) {
    "use strict";
```

```
    // Attach an anonymous function to the SAPUI5 'init' event
    sap.ui.getCore().attachInit(function () {
        var oModel = new JSONModel({
            firstName: "Harry",
            lastName: "Hawk",
            enabled: true,
            address: {
                street: "Dietmar-Hopp-Allee 16",
                city: "Walldorf",
                zip: "69190",
                country: "Germany"
            },
            "salesToDate" : 12345.6789,
            "currencyCode" : "EUR"
        });
        // Assign the model object to the SAPUI5 core
        sap.ui.getCore().setModel(oModel);
        var oResourceBundle = new ResourceModel({
            bundleName: "sap.ui.demo.db.i18n.i18n"
        });
        sap.ui.getCore().setModel(oResourceBundle, "i18n");
        // Display the XML view called "App"
        new XMLView({
            viewName: "sap.ui.demo.db.view.App"
        }).placeAt("content");
    });
});
```

We create two new model properties `salesToDate` and `currencyCode`.

webapp/view/App.view.xml

```
...
    <Panel headerText="{i18n>panel1HeaderText}" class="sapUiResponsiveMargin"
width="auto">
        <content>
            <Label text="{i18n>firstName}" class="sapUiSmallMargin"/>
            <Input value="{/firstName}" valueLiveUpdate="true" width="200px"
enabled="{/enabled}"/>
            <Label text="{i18n>lastName}" class="sapUiSmallMargin"/>
            <Input value="{/lastName}" valueLiveUpdate="true" width="200px"
enabled="{/enabled}"/>
            <CheckBox selected="{/enabled}" text="Enabled"/>
        </content>
    </Panel>
    <Panel headerText="{i18n>panel2HeaderText}" class="sapUiResponsiveMargin"
width="auto">
        <content>
            <l:HorizontalLayout>
                <l:VerticalLayout>
                    <Label class="sapUiSmallMargin" text="{i18n>address}:"/>
                    <FormattedText class="sapUiSmallMarginBegin
sapUiSmallMarginBottom" htmlText="{/address/street}&lt;br&gt;{/address/zip} {/
address/city}&lt;br&gt;{/address/country}" width="200px"/>
                    <Link class="sapUiSmallMarginBegin"
                        href="{
                            parts: [
                                '/firstName',
                                '/lastName'
                            ],
                            formatter: '.formatMail'
                        }"
                        text="{i18n>sendEmail}"/>
```

```
                </l:VerticalLayout>
                <l:VerticalLayout>
                    <Label text="{i18n>salesToDate}:" class="sapUiSmallMargin"/>
                    <Input width="200px" enabled="{/enabled}" description="{/
currencyCode}"
                        value="{
                            parts: [
                                {path: '/salesToDate'},
                                {path: '/currencyCode'}
                            ],
                            type: 'sap.ui.model.type.Currency',
                            formatOptions: {showMeasure: false}
                        }"/>
                </l:VerticalLayout>
            </l:HorizontalLayout>
        </content>
    </Panel>
</mvc:View>
```

A new pair of `Label` and `Input` elements have been created for the `salesToDate` model property. The description property of the `Input` element has been bound to the `currencyCode` model property. The value property of the `Input` element has been bound to the model properties `salesToDate` and `currencyCode`. The `{showMeasure: false}` parameter switches off the display of the currency symbol within the input field itself. This is not needed because it is being displayed using the `Input` element's description property.

webapp/i18n/i18n.properties

```
# Field labels
firstName=Vorname
lastName=Nachname
enabled=Enabled
address=Address
salesToDate=Sales to Date...
```

webapp/i18n/i18n_de.properties

```
# Field labels
firstName=Vorname
lastName=Nachname
enabled=Aktiviert
address=Adresse
salesToDate=Verk\u00e4ufe bis zum heutigen Datum
...
```

Add the missing texts to the `properties` files. Please note that special characters (non-Latin-1) have to be entered by using Unicode escape characters.

Related Information

Formatting, Parsing, and Validating Data [page 854]

Step 11: Validation Using the Message Manager

So far, we have created a currency field that can format itself correctly. The currency data type also has the ability to validate that user input adheres to to the requirements of a currency; however, data type validation functions are managed by SAPUI5, which of itself has no mechanism for reporting error messages back to the UI; therefore, we need a mechanism for reporting error messages raised by validation functions back to the user. In this step, we will connect the entire view to a feature known as the "Message Manager". Once this connection is established, any validation error messages generated based on the user input will be passed to the message manager which in turn will connect them to the appropriate view and control that caused the error.

Preview

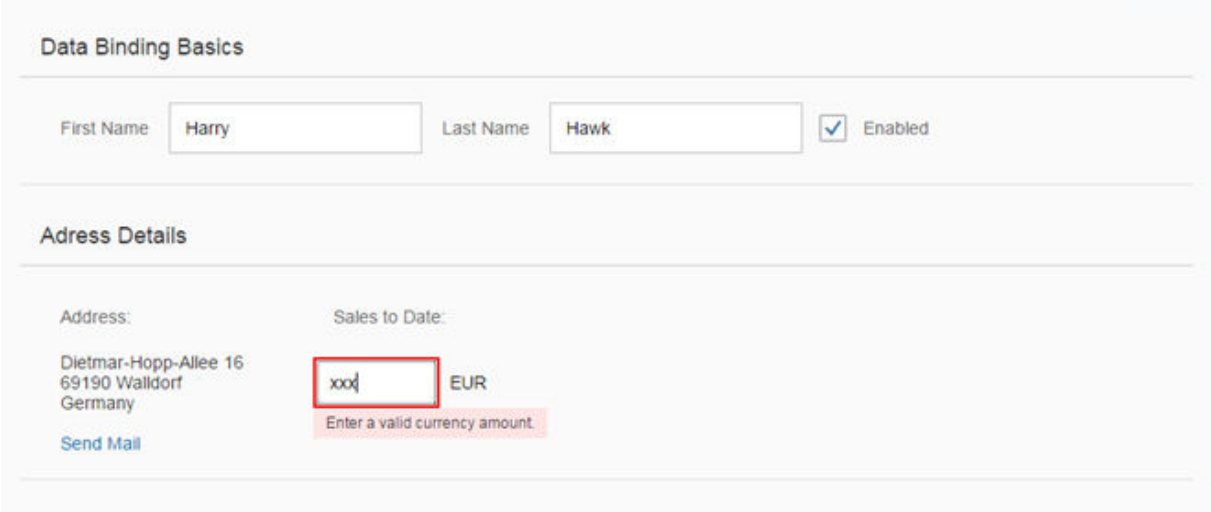

Figure 61: A message appears

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 11.

webapp/index.js

```
sap.ui.require([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/XMLView",
    "sap/ui/model/resource/ResourceModel"
], function (JSONModel, XMLView, ResourceModel) {
    "use strict";
    // Attach an anonymous function to the SAPUI5 'init' event
    sap.ui.getCore().attachInit(function () {
        var oModel = new JSONModel({
            firstName: "Harry",
```

```
            lastName: "Hawk",
            enabled: true,
            address: {
                street: "Dietmar-Hopp-Allee 16",
                city: "Walldorf",
                zip: "69190",
                country: "Germany"
            },
            "salesToDate": 12345.6789,
            "currencyCode": "EUR"
        });
        // Assign the model object to the SAPUI5 core
        sap.ui.getCore().setModel(oModel);
        var oResourceBundle = new ResourceModel({
            bundleName: "sap.ui.demo.db.i18n.i18n"
        });
        sap.ui.getCore().setModel(oResourceBundle, "i18n");
        // Display the XML view called "App"
        var oView = new XMLView({
            viewName: "sap.ui.demo.db.view.App"
        }).placeAt("content");
        // Register the view with the message manager
        sap.ui.getCore().getMessageManager().registerObject(oView, true);
        // Insert the view into the DOM
        oView.placeAt("content");
    });
});
```

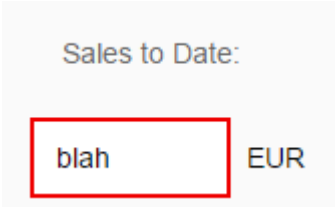
The changes to the coding are minimal:

- The XML view is now created as a named object called `oView`.
- The view object `oView` is registered with the `MessageManager`.
- Once registered, the XML view is then inserted into the DOM as before.

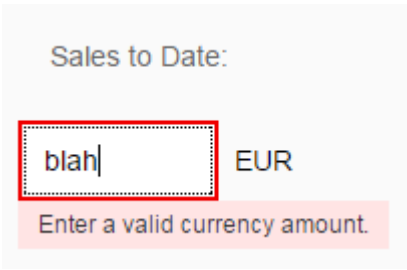
You can now enter a non-numeric value into the *Sales To Date* field and either press `Enter` or move the focus to a different UI control. This action triggers either the `onenter` or `onchange` event and then SAPUI5 executes the validation function belonging to the `sap.ui.model.type.Currency` data type.

Now that the view has been registered with the `MessageManager`, any validation error messages will be picked up by the `MessageManager`, which in turn checks its list of registered objects and then passes the error message back to the correct view for display.

Note that the field in error has a red border:



However, the error message itself will only be displayed when that particular field has focus:



Related Information

Error, Warning, and Info Messages [page 1063]

Step 12: Aggregation Binding Using Templates

Aggregation binding (or "list binding") allows a control to be bound to a list within the model data and allows relative binding to the list entries by its child controls.

It will automatically create as many child controls as are needed to display the data in the model using one of the following two approaches:

- Use template control that is cloned as many times as needed to display the data.
- Use a factory function to generate the correct control per bound list entry based on the data received at runtime.

                                }"/>
                        </attributes>
                    </ObjectListItem>
                </items>
            </List>
        </content>
    </Panel>
...
```

We add a new panel to the view.

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/library",
    "sap/ui/core/Locale",
    "sap/ui/core/LocaleData",
    "sap/ui/model/type/Currency"
], function (Controller, mobileLibrary, Locale, LocaleData, Currency) {
    "use strict";
    return Controller.extend("sap.ui.demo.db.controller.App", {
        formatMail: function(sFirstName, sLastName) {
            var oBundle = this.getView().getModel("i18n").getResourceBundle();
            return mobileLibrary.URLHelper.normalizeEmail(
                sFirstName + "." + sLastName + "@example.com",
                oBundle.getText("mailSubject", [sFirstName]),
                oBundle.getText("mailBody"));
        },
        formatStockValue: function(fUnitPrice, iStockLevel, sCurrCode) {
            var sBrowserLocale =
sap.ui.getCore().getConfiguration().getLanguage();
            var oLocale = new Locale(sBrowserLocale);
            var oLocaleData = new LocaleData(oLocale);
            var oCurrency = new Currency(oLocaleData.mData.currencyFormat);
            return oCurrency.formatValue([fUnitPrice * iStockLevel, sCurrCode],
"string");
        }
    });
});
```

webapp/model/Products.json (New)

```
{ "Products": [ {
     "ProductID": 1,
```

```
      "ProductName": "Chai",
      "SupplierID": 1,
      "CategoryID": 1,
      "QuantityPerUnit": "10 boxes x 20 bags",
      "UnitPrice": "18.0000",
      "UnitsInStock": 39,
      "UnitsOnOrder": 0,
      "ReorderLevel": 10,
      "Discontinued": false
    }, {
      "ProductID": 2,
      "ProductName": "Chang",
      "SupplierID": 1,
      "CategoryID": 1,
      "QuantityPerUnit": "24 - 12 oz bottles",
      "UnitPrice": "19.0000",
      "UnitsInStock": 17,
      "UnitsOnOrder": 40,
      "ReorderLevel": 25,
      "Discontinued": true
    }, {
      "ProductID": 3,
      "ProductName": "Aniseed Syrup",
      "SupplierID": 1,
      "CategoryID": 2,
      "QuantityPerUnit": "12 - 550 ml bottles",
      "UnitPrice": "10.0000",
      "UnitsInStock": 0,
      "UnitsOnOrder": 70,
      "ReorderLevel": 25,
      "Discontinued": false
    }, {
      "ProductID": 4,
      "ProductName": "Chef Anton's Cajun Seasoning",
      "SupplierID": 2,
      "CategoryID": 2,
      "QuantityPerUnit": "48 - 6 oz jars",
      "UnitPrice": "22.0000",
      "UnitsInStock": 53,
      "UnitsOnOrder": 0,
      "ReorderLevel": 0,
      "Discontinued": false
    }, {
      "ProductID": 5,
      "ProductName": "Chef Anton's Gumbo Mix",
      "SupplierID": 2,
      "CategoryID": 2,
      "QuantityPerUnit": "36 boxes",
      "UnitPrice": "21.3500",
      "UnitsInStock": 0,
      "UnitsOnOrder": 0,
      "ReorderLevel": 0,
      "Discontinued": true
    }]
  }
```

We now use a new JSON model file for product data.

webapp/i18n/i18n.properties

```

```

We add the missing texts.

Related Information

List Binding (Aggregation Binding) [page 828]

Step 13: Element Binding

Now we want to do something with that newly generated list. In most cases you will use a list to allow the selection of an item and then show the details of that item elsewhere. In order to achieve this, we use a form with relatively bound controls and bind it to the selected entity via element binding.

Preview

</mvc:View>
```

Now we have an empty form. In order to fill this form with data, we will bind the whole panel to the path of the element which we clicked in the list. We need to add a `press`-event handler to the items in the list.

webapp/view/App.views.xml

```
...
  <Panel headerText="{i18n>panel4HeaderText}" class="sapUiResponsiveMargin"
width="auto">
    <content>
      <List headerText="{i18n>productListTitle}" items="{products>/Products}">
        <items>
          <ObjectListItem
              press=".onItemSelected"
            type="Active"
              title="{products>ProductName}"
              number="{ parts: [{path: 'products>UnitPrice'},
                                {path: '/currencyCode'}],
                        type: 'sap.ui.model.type.Currency',
                        formatOptions: { showMeasure: false }
                      }"
              numberUnit="{/currencyCode}">
              <attributes>
...
```

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/library",
    "sap/ui/core/Locale",
    "sap/ui/core/LocaleData",
    "sap/ui/model/type/Currency"
], function (Controller, mobileLibrary, Locale, LocaleData, Currency) {
    "use strict";
    return Controller.extend("sap.ui.demo.db.controller.App", {
        formatMail: function(sFirstName, sLastName) {
            var oBundle = this.getView().getModel("i18n").getResourceBundle();
            return mobileLibrary.URLHelper.normalizeEmail(
                sFirstName + "." + sLastName + "@example.com",
                oBundle.getText("mailSubject", [sFirstName]),
                oBundle.getText("mailBody"));
        },
        formatStockValue: function(fUnitPrice, iStockLevel, sCurrCode) {
            var sBrowserLocale =
sap.ui.getCore().getConfiguration().getLanguage();
            var oLocale = new Locale(sBrowserLocale);
            var oLocaleData = new LocaleData(oLocale);
            var oCurrency = new Currency(oLocaleData.mData.currencyFormat);
            return oCurrency.formatValue([fUnitPrice * iStockLevel, sCurrCode],
"string");
        },
        onItemSelected: function(oEvent) {
            var oSelectedItem = oEvent.getSource();
            var oContext = oSelectedItem.getBindingContext("products");
            var sPath = oContext.getPath();
            var oProductDetailPanel = this.byId("productDetailsPanel");
            oProductDetailPanel.bindElement({ path: sPath, model: "products" });
        }
    });
});
```

In the controller, we bind the newly created panel to the correct item whenever it is pressed.

We can now click on an element in the list and see its details in the panel below. We can even edit these details and these changes are directly shown in the list because we use two-way binding.

> **i** Note
>
> Element bindings can also be relative to its parent context.

Context Binding (Element Binding) [page 824]

Step 14: Expression Binding

Expression binding allows you to display a value on the screen that has been calculated from values found in some model object. This way simple formatting or calculations can be inserted directly into the data binding string. In this example, we will change the color of the price depending on whether it is above or below some arbitrary threshold. The threshold value is also stored in the JSON model.

Preview

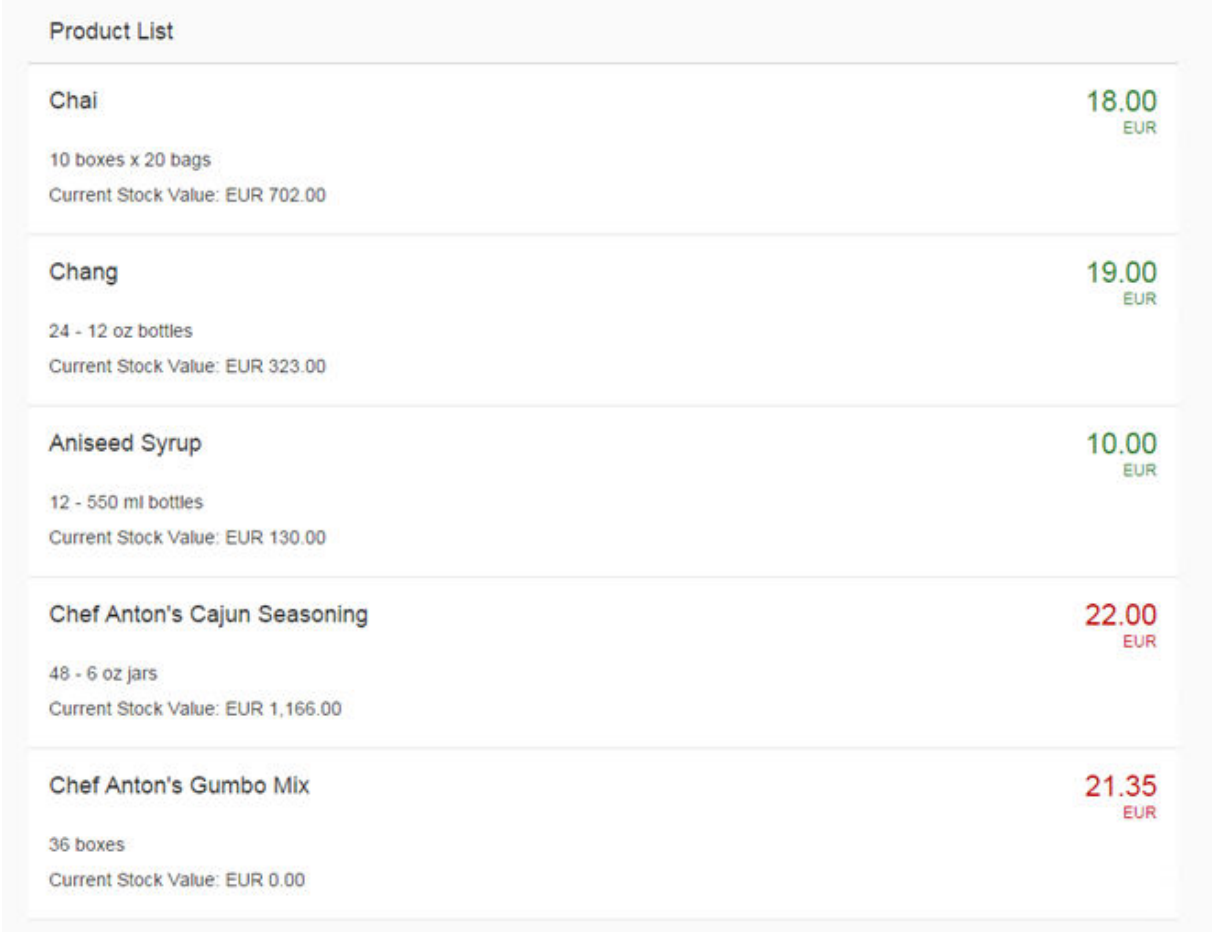

Figure 64: Values formatted

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 14.

webapp/view/App.view.xml

```
...
        </content>
    </Panel>
    <Panel headerText="{i18n>panel3HeaderText}" class="sapUiResponsiveMargin"
width="auto">
        <content>
            <List headerText="{i18n>productListTitle}" items="{products>/
Products}">
                <items>
                    <ObjectListItem
                        press=".onItemSelected"
                        type="Active"
```

```
                        title="{products>ProductName}"
                        number="{
                            parts: [
                                {path: 'products>UnitPrice'},
                                {path: '/currencyCode'}
                            ],
                            type: 'sap.ui.model.type.Currency',
                            formatOptions: { showMeasure: false }
                        }"
                        numberUnit="{/currencyCode}"
                        numberState="{= ${products>UnitPrice} > ${/
priceThreshold} ? 'Error' : 'Success' }">
                        <attributes>
                            <ObjectAttribute text="{products>QuantityPerUnit}"/>
                            <ObjectAttribute title="{i18n>stockValue}"
                                text="{
                                    parts: [
                                        {path: 'products>UnitPrice'},
                                        {path: 'products>UnitsInStock'},
                                        {path: '/currencyCode'}
                                    ],
                                    formatter: '.formatStockValue'
                                }"/>
                        </attributes>
                    </ObjectListItem>
                </items>
            </List>
        </content>
    </Panel>
...
```

In the XML view, we add a new `numberState` property to the `ObjectListItem` element within the `List`. The value of this property is an expression that will be evaluated for each item.

webapp/index.js

```
sap.ui.require([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/XMLView",
    "sap/ui/model/resource/ResourceModel"
], function (JSONModel, XMLView, ResourceModel) {
    "use strict";
    // Attach an anonymous function to the SAPUI5 'init' event
    sap.ui.getCore().attachInit(function () {
        var oProductModel = new JSONModel();
        oProductModel.loadData("./model/Products.json");
        sap.ui.getCore().setModel(oProductModel, "products");
        var oModel = new JSONModel({
            firstName: "Harry",
            lastName: "Hawk",
            enabled: true,
            address: {
                street: "Dietmar-Hopp-Allee 16",
                city: "Walldorf",
                zip: "69190",
                country: "Germany"
            },
            "salesToDate": 12345.6789,
            "priceThreshold": 20,
            "currencyCode": "EUR"
        });
        // Assign the model object to the SAPUI5 core
```

```
        sap.ui.getCore().setModel(oModel);
        var oResourceBundle = new ResourceModel({
            bundleName: "sap.ui.demo.db.i18n.i18n"
        });
        sap.ui.getCore().setModel(oResourceBundle, "i18n");
        // Display the XML view called "App"
        var oView = new XMLView({
            viewName: "sap.ui.demo.db.view.App"
        }).placeAt("content");
        // Register the view with the message manager
        sap.ui.getCore().getMessageManager().registerObject(oView, true);
        // Insert the view into the DOM
        oView.placeAt("content");
    });
});
```

We add a new property called `priceThreshold` against which each invoice value will be checked.

As a result of binding an expression to the `numberState` property, the error status (color) of the price field will change depending on the invoice value.

Look at the following two expressions:

- `numberState="{= ${products>UnitPrice} > ${/priceThreshold} ? 'Error' : 'Success' }"`
- `numberState="{= ${products>UnitPrice} <= ${/priceThreshold} ? 'Success' : 'Error' }"`

Can you see why one of these expressions will work, and the other will not?

Logically, both expressions are identical; yet the first one works, and the second does not: it produces only an empty screen and an "Invalid XML" message in the browser's console... Hmmm, what's going on here?

In order to understand why this situation occurs, you must understand how XML files are parsed.

When an XML file is parsed, certain characters have a special (that is, high priority) meaning to the XML parser. When such characters are encountered, they are **always** interpreted to be part of the XML definition itself and not part of any other content that might exist within the XML document.

As soon as the XML parser encounters one of these high-priority characters (in this case, a less-than (<) character), it will always be interpreted as the start of a new XML tag – irrespective of any other meaning that character might have within the context of the expression. This is known as a **syntax collision**.

In this case, the collision occurs between the syntax of XML and the syntax of the JavaScript-like expression language used by SAPUI5.

Therefore, this statement fails because the less-than character is interpreted as the start of an XML tag:
`numberState="{= ${products>UnitPrice} <= ${/priceThreshold} ? 'Success' : 'Error' }"`

This particular problem can be avoided in one of two ways:

- Reverse the logic of the condition (use "greater than or equal to" instead of "less than")
- Use the escaped value for the less-than character: `numberState="{= ${products>UnitPrice} <= ${/priceThreshold} ? 'Success' : 'Error' }"`

Since the use of an escaped character is not so easy to read, the preferred approach is to reverse the logic of the condition and use a greater-than character instead.

The ampersand (`&`) character also has a high priority meaning to the XML parser. This character will always be interpreted to mean "The start of an escaped character". So if you wish to use the Boolean `AND` operator (`&&`) in a condition, you must escape both ampersand characters (`&&`).

Expression Binding [page 845]

Step 15: Aggregation Binding Using a Factory Function

Instead of hard-coding a single template control, we use a factory function to generate different controls based on the data received at runtime. This approach is much more flexible and allows complex or heterogeneous data to be displayed.

Preview

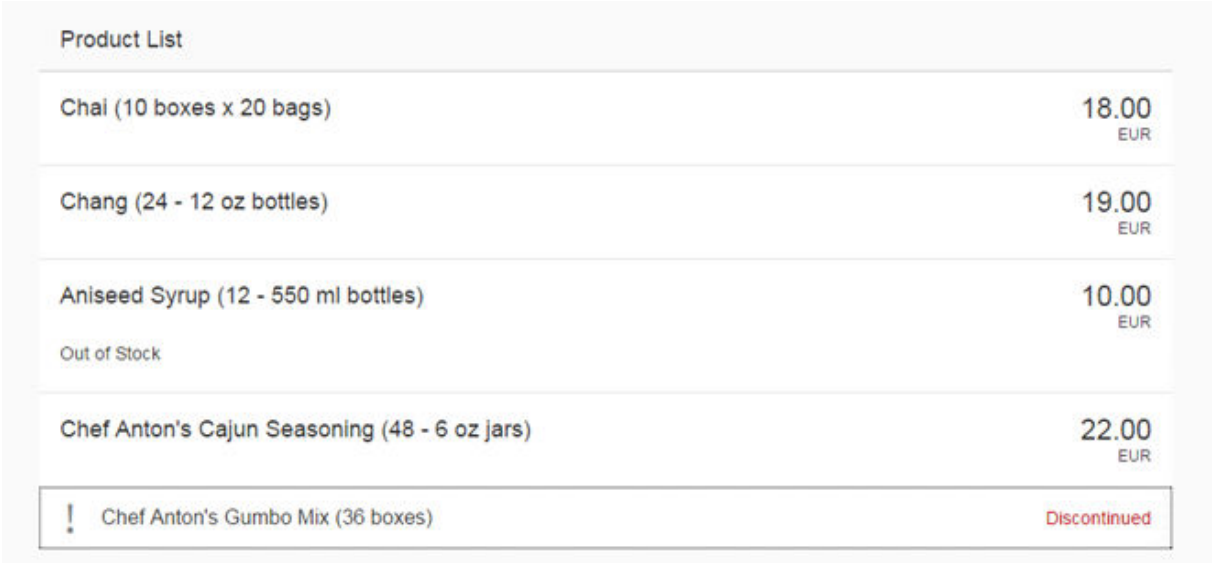

Figure 65: Controls generated based on data

Coding

You can view and download all files in the Demo Kit at Data Binding - Step 15.

webapp/view/App.view.xml

```
...
    <Panel headerText="{i18n>panel3HeaderText}" class="sapUiResponsiveMargin"
width="auto">
        <content>
            <List
                id="ProductList"
                headerText="{i18n>productListTitle}"
                items="{
                    path: 'products>/Products',
                    factory: '.productListFactory'
                }">
                <dependents>
                    <core:Fragment
fragmentName="sap.ui.demo.db.view.ProductSimple" type="XML"/>
                    <core:Fragment
fragmentName="sap.ui.demo.db.view.ProductExtended" type="XML"/>
                </dependents>
            </List>
        </content>
    </Panel>
...
```

The `List` XML element that previously held the product list is now reduced simply to a named, but otherwise empty placeholder. Without a factory function to populate it, this `List` would always remain empty.

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/library",
    "sap/ui/core/Locale",
    "sap/ui/core/LocaleData",
    "sap/ui/model/type/Currency",
    "sap/m/ObjectAttribute"
], function (Controller, mobileLibrary, Locale, LocaleData, Currency,
ObjectAttribute) {
    "use strict";
    return Controller.extend("sap.ui.demo.db.controller.App", {
        formatMail: function(sFirstName, sLastName) {
            var oBundle = this.getView().getModel("i18n").getResourceBundle();
            return mobileLibrary.URLHelper.normalizeEmail(
                sFirstName + "." + sLastName + "@example.com",
                oBundle.getText("mailSubject", [sFirstName]),
                oBundle.getText("mailBody"));
        },
        formatStockValue : function(fUnitPrice, iStockLevel, sCurrCode) {
            var sBrowserLocale =
sap.ui.getCore().getConfiguration().getLanguage();
            var oLocale = new Locale(sBrowserLocale);
            var oLocaleData = new LocaleData(oLocale);
            var oCurrency = new Currency(oLocaleData.mData.currencyFormat);
            return oCurrency.formatValue([fUnitPrice * iStockLevel, sCurrCode],
"string");
        },
        onItemSelected : function(oEvent) {
            var oSelectedItem = oEvent.getSource();
            var oContext = oSelectedItem.getBindingContext("products");
            var sPath = oContext.getPath();
```

```
            var oProductDetailPanel = this.byId("productDetailsPanel");
            oProductDetailPanel.bindElement({ path: sPath, model: "products" });
        },
        productListFactory : function(sId, oContext) {
            var oUIControl;

            // Decide based on the data which dependent to clone
            if (oContext.getProperty("UnitsInStock") === 0 &&
oContext.getProperty("Discontinued")) {
                // The item is discontinued, so use a StandardListItem
                oUIControl = this.byId("productSimple").clone(sId);
            } else {
                // The item is available, so we will create an ObjectListItem
                oUIControl = this.byId("productExtended").clone(sId);

                // The item is temporarily out of stock, so we will add a status
                if (oContext.getProperty("UnitsInStock") < 1) {
                    oUIControl.addAttribute(new ObjectAttribute({
                        text : {
                            path: "i18n>outOfStock"
                        }
                    }));
                }
            }

            return oUIControl;
        }
    });
});
```

In the `App` controller, we create a new function called `productListFactory`. A factory function returns a control for the associated binding context, similar to the XML templates we have defined in the previous steps. The types of controls returned by this factory function must suit the items aggregation of the `sap.m.List` object. In this case, we return either a `StandardListItem` or an `ObjectListItem` based on the data stored in the context of the item to be created.

We decide which type of control to return by checking the current stock level and whether or not the product has been discontinued. For both options, we prepare and load an XML fragment so that we can define the view logic declaratively and assign the current controller. If the stock level is zero and the product has also been discontinued, then we use the `ProductSimple` XML fragment, otherwise the `ProductExtended` XML fragment.

The XML fragments need to be loaded only once for each case, so we create a Singleton by storing a helper variable on the controller and only loading it once. For each item of the list, we clone the corresponding control stored on the controller. This protected method creates a fresh copy of a control that we can bind to the context of the list item. Please note: In a factory function, you are responsible for the life cycle of the control you create.

If the product is not discontinued but the stock level is zero, we are temporarily out of stock. In this case, we add a single `ObjectAttribute` that adds the *Out of Stock* message to the control using JavaScript. Similar to declarative definitions in the XML view or fragments, we can bind properties using data binding syntax. In this case, we bind the text to a property in the resource bundle. Since the `Attribute` is a child of the list item, it has access to all assigned models and the current binding context.

Finally, we return the control that is displayed inside the list.

webapp/view/ProductSimple.fragment.xml (new)

```
<core:FragmentDefinition
    xmlns="sap.m"
    xmlns:core="sap.ui.core">
    <StandardListItem
        id="productSimple"

        icon="sap-icon://warning"
        title="{products>ProductName} ({products>QuantityPerUnit})"
        info="{i18n>Discontinued}"
        type="Active"
        infoState="Error"
        press=".onItemSelected">
    </StandardListItem>
</core:FragmentDefinition>
```

The XML fragment defines a `StandardListItem` that is used if the stock level is zero and the product has also been discontinued. This is our simple use case where we just define a warning icon and a *Product Discontinued* message in the `info` property.

webapp/view/ProductExtended.fragment.xml (new)

```
<core:FragmentDefinition
    xmlns="sap.m"
    xmlns:core="sap.ui.core">
    <ObjectListItem
        id="productExtended"
        title="{products>ProductName} ({products>QuantityPerUnit})"
        number="{
            parts: [
                {path: 'products>UnitPrice'},
                {path: '/currencyCode'}
            ],
            type: 'sap.ui.model.type.Currency',
            formatOptions : {
                showMeasure : false
            }
        }"
        type="Active"
        numberUnit="{/currencyCode}"
        press=".onItemSelected">
    </ObjectListItem>
</core:FragmentDefinition>
```

In our extended use case, we create an `ObjectListItem` to display more details of the product. The properties are bound to the fields of the current data binding context and therefore can use types, formatters, and all handlers that are defined in the assigned controller.

However, more complex logic can't be defined declaratively in XML. Therefore, when the stock level is zero, we add a single `ObjectAttribute` that displays the *Out of Stock* message in the controller using JavaScript.

webapp/i18n/i18n.properties

```
...
# Product Details
...
outOfStock=Out of Stock
```

webapp/i18n/i18n_de.properties

```
...
# Product Details
...
outOfStock=Nicht vorr\u00e4tig
```

We add the missing texts to the `properties` files.

That's all - you completed the Data Binding tutorial!

Using Factory Functions [page 831]

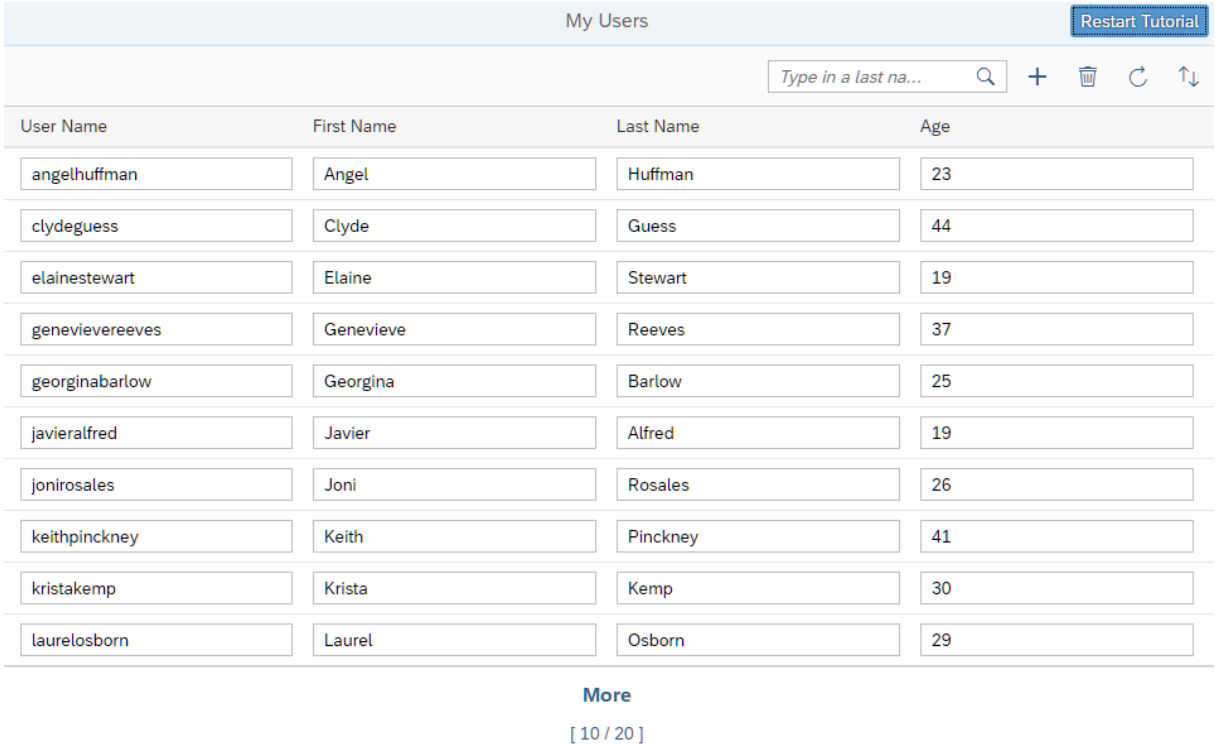
OData V4

In this tutorial, we explore how features of OData V4 can be used in SAPUI5. We write a small app that consumes data from an OData V4 service to understand how to access, modify, aggregate, and filter data in an OData V4 model.

OData is a standard protocol for creating and consuming data by using simple HTTP and REST APIs for create, read, update, delete (CRUD) operations.

We start with an initial app that simply retrieves data from an OData V4 service and displays it as a plain list.

Preview



→ Tip

You don't have to do all tutorial steps sequentially, you can jump directly to any step you want. In each step, download the code from the previous step, copy it to your workspace, and make sure that the application runs by calling the `webapp/index.html` file.

You can view and download the samples for all steps in the Demo Kit at OData V4. Depending on your development environment you might have to adjust resource paths and configuration entries.

For more information, check the following sections of the tutorial overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]

OData Standard Protocol
OData V4 Model [page 918]
Basic Tutorial on the *OData* Home Page

Step 1: The Initial App

We start by setting up a simple app that loads data from an OData service and displays it in a table. We use a mock server to simulate requests to and responses from the service.

The structure and data model created in this step will be used throughout this tutorial to illustrate the OData V4 features in SAPUI5.

Preview

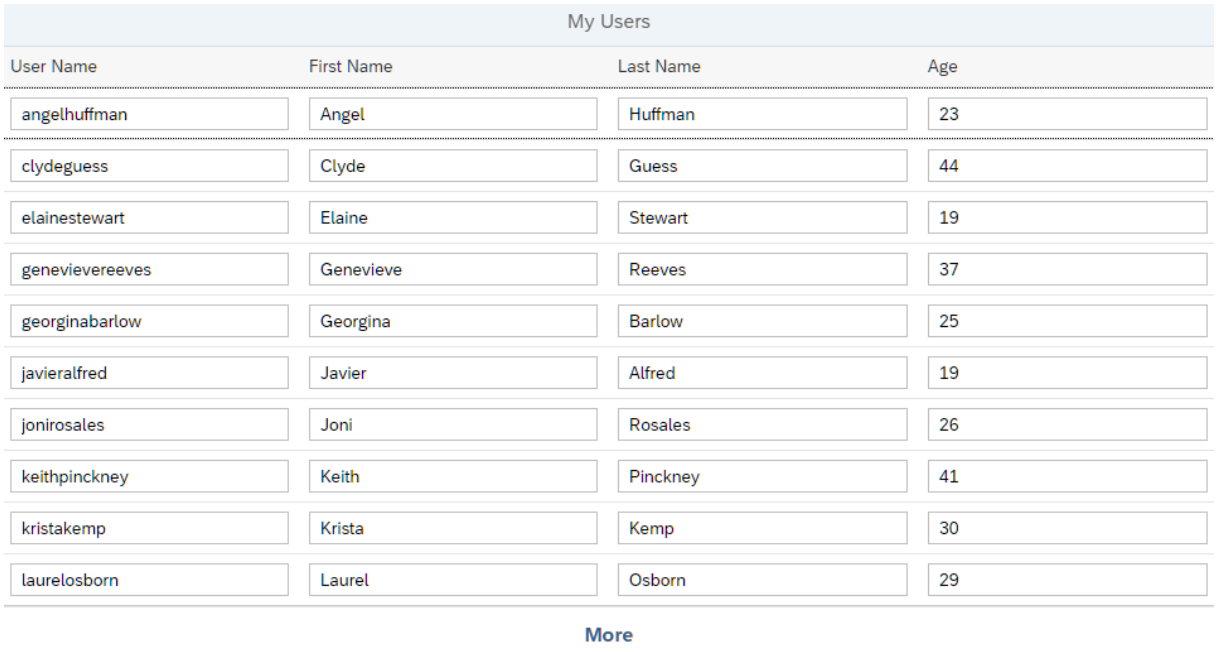

Figure 66: Initial app with a simple table

Setup

To set up your project for this tutorial, download the files at OData V4 - Step 1. Copy or import the code to your workspace and make sure that the application runs by calling the `webapp/index.html` file.

Depending on your development environment, you might have to adjust resource paths and configuration entries. The project structure and the files provided with this tutorial are explained in detail in the Walkthrough [page 69] tutorial.

You should now have the following files:

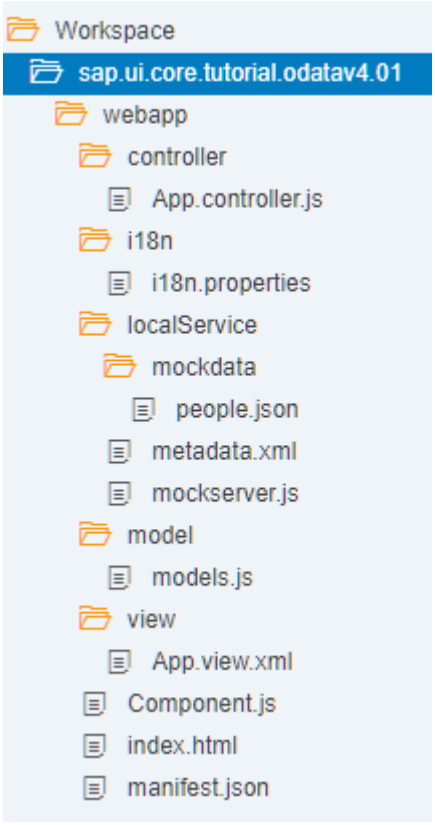

Figure 67: Folder structure with downloaded files

The Initial App

The downloaded code includes an app that displays a table containing a table of users. For performance reasons, the table only loads 10 users at a time. More data can be retrieved by using the *More* button at the bottom of the page.

During the implementation of the app, we use local mock data so that we can concentrate on the application logic without dealing with back-end readiness or connectivity issues. We use the *TripPin* sample service as a "real" OData service.

The most important files are the following:

`webapp/index.html`

This file defines the home page of the app. It contains the bootstrap script and tells the runtime where to find our custom resources. It also initializes the mock server that intercepts all requests to the real *TripPin* service and sends back mock responses.

`webapp/manifest.json`

The `manifest.json` descriptor file contains the app configuration. In the `sap.app` section, the OData V4 service is configured as the default service:

```
"dataSources": {
    "default": {
        "uri": "https://services.odata.org/TripPinRESTierService/(S(id))/",
        "type": "OData",
```

```
        "settings": {
            "odataVersion": "4.0"
        }
    }
}
```

Mock server (`webapp/localService/*`)

> **i** Note
>
> The mock server included in this tutorial is only meant to support the features needed in this tutorial. Currently, there is no "general-purpose mock server" for application development available with OData V4 (like there is for OData V2).

The `mockserver.js` file contains the implementation of the mock server. It is quite simple since the mock server is only used to simulate certain types of requests to the *TripPin* service.

The `metadata.xml` file contains the service metadata that includes, for example, entity types and entity sets. Those define the possible requests as well as the structure of responses.

To be able to add data to the emulated OData responses, we have to store the entities for each entity type we use in a JSON file: The `people.json` file contains some data that is used for the mock service responses.

In this tutorial, we only use the entity type `Person` of the *TripPin* service. The entities of type `Person` are collected in the entity set `People`. Each `Person` has a key property `UserName` and the properties `Age`, `FirstName`, and `LastName`.

Descriptor for Applications, Components, and Libraries [page 734]

Step 2: Data Access and Client-Server Communication

In this step, we see how the `Table` that is bound to the `People` entity set initially requests its data, and how the data can be refreshed. We use the *Console* tab in the browser developer tools to monitor the communication between the browser and the server. We see the initial request as well as the requests for refreshing the data.

Preview

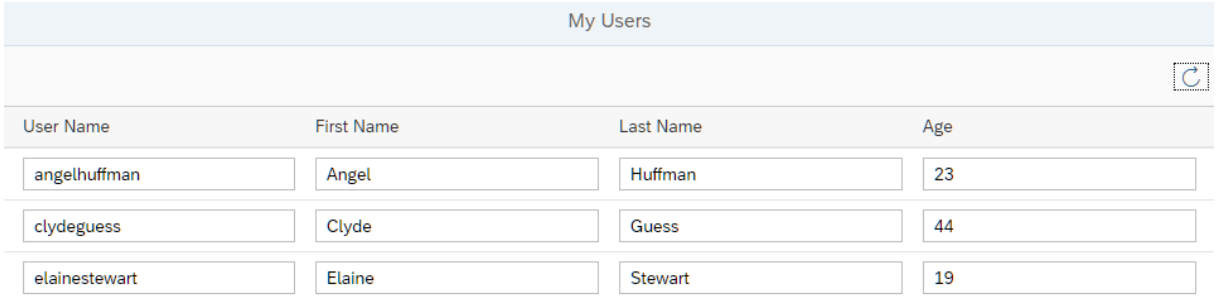

Figure 68: App with a toolbar that contains a *Refresh* button

Coding

You can view and download all files at OData V4 - Step 2.

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageToast",
    "sap/m/MessageBox",
    "sap/ui/model/json/JSONModel"
], function (Controller, MessageToast, MessageBox, JSONModel) {
    "use strict";
    return Controller.extend("sap.ui.core.tutorial.odatav4.controller.App", {
        onInit : function () {
            var oJSONData = {
                busy : false
            };
            var oModel = new JSONModel(oJSONData);
            this.getView().setModel(oModel, "appView");
        },

        onRefresh : function () {
            var oBinding = this.byId("peopleList").getBinding("items");

            if (oBinding.hasPendingChanges()) {
                MessageBox.error(this._getText("refreshNotPossibleMessage"));
                return;
            }
            oBinding.refresh();
            MessageToast.show(this._getText("refreshSuccessMessage"));
```

```
        },

        _getText : function (sTextId, aArgs) {
            return
this.getOwnerComponent().getModel("i18n").getResourceBundle().getText(sTextId,
aArgs);

        }
    });
});
```

We add the event handler `onRefresh` to the controller. In this method, we retrieve the current data binding of the table. If the binding has unsaved changes, we display an error message, otherwise we call `refresh()` and display a success message.

> **i** Note
>
> At this stage, our app cannot have unsaved changes. We will change this in Step 6.

We also add the private method `_getText` to retrieve translatable texts from the resource bundle (`i18n` model).

webapp/view/App.view.xml

```
...
<Page title="{i18n>peoplePageTitle}">
    <content>
        <Table
            id="peopleList"
            growing="true"
            growingThreshold="10"
            items="{
                path: '/People'
            }">
            <headerToolbar>
                <OverflowToolbar>
                    <content>
                        <ToolbarSpacer/>
                        <Button
                            id="refreshUsersButton"
                            icon="sap-icon://refresh"
                            tooltip="{i18n>refreshButtonText}"
                            press=".onRefresh"/>
                    </content>
                </OverflowToolbar>
            </headerToolbar>
            <columns>
...
```

We add the `headerToolbar` with a single `Button` to the `Table`. The button has a `press` event to which we attach an event handler called `onRefresh`.

webapp/i18n/i18n.properties

```
# App Descriptor
...
# Toolbar
#XTOL: Tooltip for refresh data
refreshButtonText=Refresh Data
# Table Area
...
# Messages
#XMSG: Message for refresh failed
refreshNotPossibleMessage=Before refreshing, please save or revert your changes

#XMSG: Message for refresh succeeded
refreshSuccessMessage=Data refreshed
```

We add the tooltip and message texts to the `properties` file.

Under the Hood

To get more insight into the client-server communication, we open the *Console* tab of the browser developer tools and then reload the app.

> **i Note**
>
> To monitor the client-server communication in a productive app, you would use the *Network* tab of the developer tools.
>
> In this tutorial, we are using a mock server instead of a real OData service so that we can execute the code in every environment. The mock server does not generate any network traffic, so we use the *Console* tab to monitor the communication.
>
> If you want to switch to the real service, do the following:
>
> 1. In the `index.html` file, remove the line `data-sap-ui-oninit="module:sap/ui/core/tutorial/odatav4/initMockServer"`.
> 2. Check the URI of the default data source in the `manifest.json` file. Depending on the environment, change it to something that avoids cross-origin resource sharing (CORS) problems. For more information, see Request Fails Due to Same-Origin Policy (Cross-Origin Resource Sharing - CORS) [page 1391]

We search for the following mock server requests:

- http://services.odata.org/TripPinRESTierService/(S(id))/$metadata
  This first request fetches the metadata that describes the entities of the service (see also OData Version 4.0. Part 3: Common Schema Definition Language (CSDL) Plus Errata 03).
  The server responds with an XML file that describes the entities, for example, entity type `"Person"` has several properties such as `UserName`, `FirstName`, `LastName`, and `Age`.

  > **i Note**
  >
  > The URL contains the session ID `(S(id))`. Since the public *TripPin* service can be used by multiple persons at the same time, the session ID separates read and write requests from different sources. You

> could use a different ID or request the service without a specified session ID. In the latter case, you will get a response with a new, random session ID.

- http://services.odata.org/TripPinRESTierService/(S(id))/People?$select=Age,FirstName,LastName,UserName&$skip=0&$top=10 .
  The second request fetches the first 10 entities from the OData service. The `growingThreshold="10"` setting in the implementation of the `Table` control in the `App.view.xml` file defines that only 10 entities are fetched at the same time from the `'/people'` path. Further data is only loaded when requested from the user interface (`growing="true"`). Therefore, there are only 10 entities requested at the same time by using `$skip=0&$top=10` (see System Query Option $top and $skip in the Basic Tutorial on the OData home page.)
  This request explicitly lists the fields that should be included in the response by using the `$select` query option. Although the *TripPin* service has more fields in its `People` entity set, only those four are included in the response. This is a feature of the OData V4 Model called "automatic determination of `$select`", or "auto-`$select`". It helps restricting the size of responses to what is really needed. The `ODataModel` computes the required fields from binding paths specified for controls. This feature is not active by default. In our case, this is activated by setting the `autoExpandSelect` property to `true` when instantiating the model in the `manifest.json` descriptor file .

API Reference: `sap.ui.model.odata.v4.ODataListBinding.refresh`
Troubleshooting Tutorial Step 1: Browser Developer Tools [page 196]

Step 3: Automatic Data Type Detection

In this step, we use the automatic data type detection of the OData V4 model to parse, validate, and format user entries. The service metadata contains type information for the properties of each entity.

The OData V4 Model utilizes this information to compute the corresponding SAPUI5 type, including constraints, and sets this type to the SAPUI5 property binding for the entity property. For example, for `<Input value={Age}/>` the SAPUI5 type `Int64` is used, which corresponds to the OData type `Edm.Int64`.

Preview

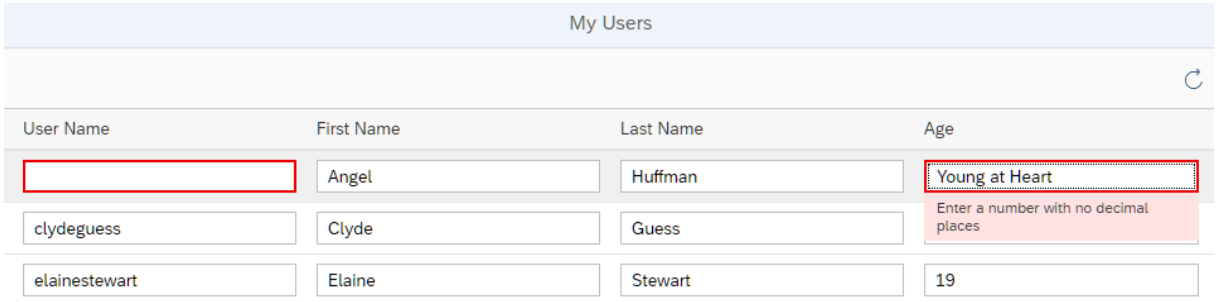

Figure 69: Input does not match the underlying data type

Coding

You can view and download all files at OData V4 - Step 3.

webapp/manifest.json

```
{
    "_version": "1.12.0",
    "sap.app": {...
    },
    "sap.ui": {
        "technology": "UI5",
        "deviceTypes": {

        }
    },
    "sap.ui5": {
        "rootView": {
        ...
        },
        "dependencies": {
            ...
            }
        },
        "contentDensities": {
            ...
        },
        "handleValidation": true,

        "models": {
            ...
            }
        }
    },
    "sap.platform.hcp": {
        ...
    }
```

In the `manifest.json` descriptor file, we add the `"handleValidation": true` setting. This makes sure that any validation errors that are detected by the SAPUI5 types are shown on the UI using the message manager.

We now run the app using the `index.html` file and enter values that don't match the type and constraints given in the metadata file. For example, enter the string value **`Young at Heart`** in field *Age*, which requires an integer input (SAPUI5 type `sap.ui.model.odata.type.Int64`, corresponding to OData type `Edm.Int64`), or remove an entry from the *User Name* or *First Name* fields, which are mandatory. Fields with incorrect entries are highlighted and an error message is displayed.

> **i** Note
>
> If you explicitly define a type in the binding info of a control, the automatic type detection for that binding will be turned off. For example, if you change the `Input` for `Age` in the view to `<Input value="{path:'Age', type:'sap.ui.model.type.String'}/>`, the `String` type will be used, not the `Int64` type from the service metadata.

localService/metadata.xml

```
<EntityType Name="Person">
    <Key>
        <PropertyRef Name="UserName"/>
    </Key>
    <Property Name="UserName" Type="Edm.String" Nullable="false" />
    <Property Name="FirstName" Type="Edm.String" />
    <Property Name="LastName" Type="Edm.String"/>
    <Property Name="MiddleName" Type="Edm.String"/>
    <Property Name="Gender"
Type="Microsoft.OData.Service.Sample.TrippinInMemory.Models.PersonGender"
             Nullable="false"/>
    <Property Name="Age" Type="Edm.Int64" />
```

To make the *First Name* optional, we remove the parameter `Nullable="false"` from the `FirstName` property. You can play around with the settings for the other properties, for example, change the type of property `Age` to `Type="Edm.String"` to allow free text.

> **→** Tip
>
> To see the metadata of an OData service, you append the `$metadata` variable to the URL of the service. You can try this, for example, with http://services.odata.org/TripPinRESTierService/ and http://services.odata.org/TripPinRESTierService/$metadata

Sample for `sap.ui.core.mvc.XMLView`: *XML Templating: UI5 OData types*

Step 4: Filtering, Sorting, and Counting

In this step, we add features to filter, sort, and count the user data by using the OData V4 model API to apply OData system query options `$filter`, `$orderby`, and `$count`.

Preview

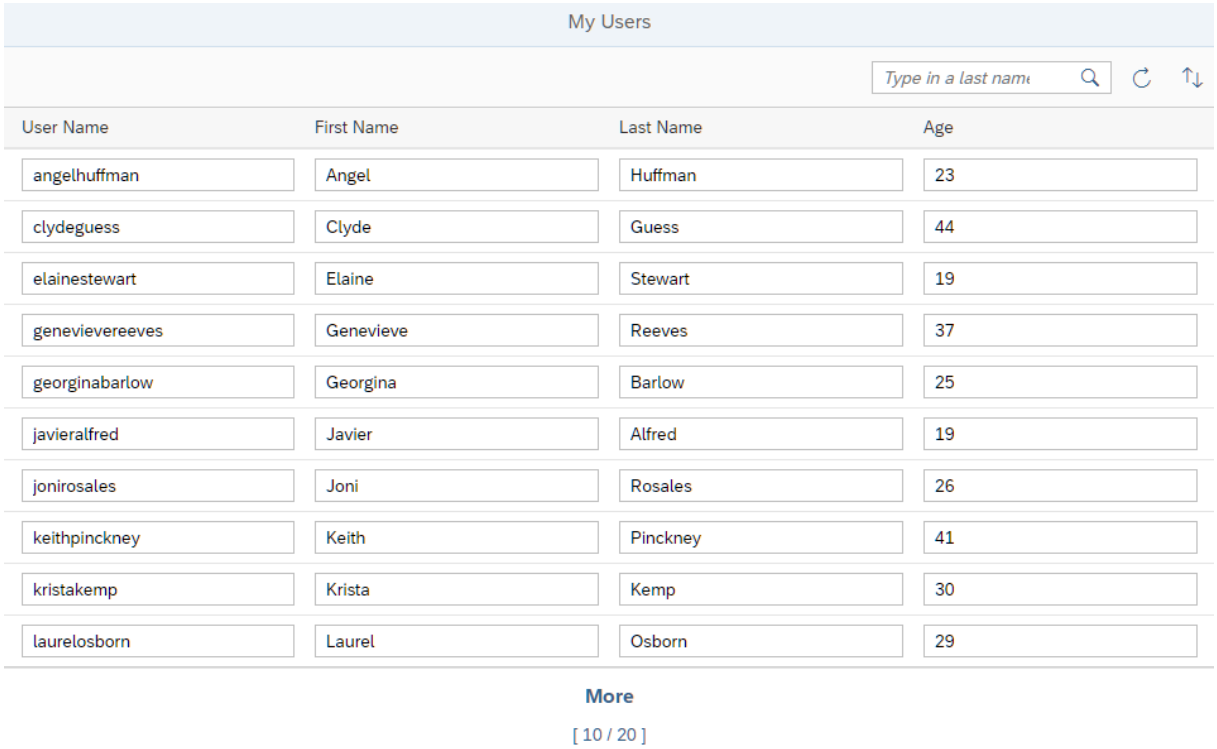

Figure 70: App now has a search field, the entries can be sorted, and you can see how many entities are loaded and how many more are available

Coding

You can view and download all files at OData V4 - Step 4.

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageToast",
    "sap/m/MessageBox",
    "sap/ui/model/Sorter",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    "sap/ui/model/FilterType",
```

```
    "sap/ui/model/json/JSONModel"
], function (Controller, MessageToast, MessageBox, Sorter, Filter,
FilterOperator, FilterType, JSONModel) {
    "use strict";
    return Controller.extend("sap.ui.core.tutorial.odatav4.controller.App", {
        onInit : function () {
            var oJSONData = {
                busy : false,
                order : 0
            };
            var oModel = new JSONModel(oJSONData);
            this.getView().setModel(oModel, "appView");
        },
        onRefresh : function () {
        ...
        },

        onSearch : function () {
            var oView = this.getView(),
                sValue = oView.byId("searchField").getValue(),
                oFilter = new Filter("LastName", FilterOperator.Contains,
sValue);

            oView.byId("peopleList").getBinding("items").filter(oFilter,
FilterType.Application);
        },

        onSort : function () {
            var oView = this.getView(),
                aStates = [undefined, "asc", "desc"],
                aStateTextIds = ["sortNone", "sortAscending", "sortDescending"],
                sMessage,
                iOrder = oView.getModel("appView").getProperty("/order");

            iOrder = (iOrder + 1) % aStates.length;
            var sOrder = aStates[iOrder];

            oView.getModel("appView").setProperty("/order", iOrder);
            oView.byId("peopleList").getBinding("items").sort(sOrder && new
Sorter("LastName", sOrder === "desc"));

            sMessage = this._getText("sortMessage",
[this._getText(aStateTextIds[iOrder])]);
            MessageToast.show(sMessage);
        },
        _getText : function (sTextId, aArgs) {
        ...
        }
    });
});
```

We add the `onSearch` and `onSort` event handlers for the *Search* field and the *Sort* button to the controller. We also enhance the `appView` model to store the active sorting order.

The `onSearch` event handler filters the table for people whose last name contains any string value entered in the *Search* field. We define a `sap.ui.model.Filter` and apply it to the binding of the `Table` using the `filter` method. The binding will then automatically retrieve filtered data from the OData V4 service and update the `Table`.

When the request is triggered, only entities that match the given filter criteria are requested from the OData V4 service.

> **i Note**
>
> Filters of OData services are case-sensitive. If you prefer a non case-sensitive search, implement it in the controller logic.

The `onSort` event handler requests the data unordered, or in ascending order, or descending order. Each time the *Sort* button is clicked, the next sort order is applied. The sorting is applied to the table by calling the `sort` method of the list binding with a new `sap.ui.model.Sorter`.

> **i Note**
>
> The features of filtering and sorting can also be combined.

We add the `order` property to variable `oJSONData` in `onInit` method. This property stores the current sort order.

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.core.tutorial.odatav4.controller.App"
    displayBlock="true"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Shell>
        <App busy="{appView>/busy}" class="sapUiSizeCompact">
            <pages>
                <Page title="{i18n>peoplePageTitle}">
                    <content>
                        <Table
                            id="peopleList"
                            growing="true"
                            growingThreshold="10"
                            items="{
                                path: '/People',
                                parameters: {
                                    $count: true
                                }
                            }">
                            <headerToolbar>
                                <OverflowToolbar>
                                    <content>
                                        <ToolbarSpacer/>
                                        <SearchField
                                            id="searchField"
                                            width="20%"

placeholder="{i18n>searchFieldPlaceholder}"
                                            search=".onSearch"/>
                                        <Button
                                            id="refreshUsersButton"
                                            icon="sap-icon://refresh"
                                            tooltip="{i18n>refreshButtonText}"
                                            press=".onRefresh"/>
                                        <Button
                                            id="sortUsersButton"
                                            press="onSort"
                                            tooltip="{i18n>sortButtonText}"
                                            icon="sap-icon://sort"/>
```

```
                                    </content>
                                </OverflowToolbar>
                            </headerToolbar>
                            <columns>
                                <Column id="userNameColumn">
                                    <Text text="{i18n>userNameLabelText}"/>
                                </Column>
                                <Column id="firstNameColumn">
                                    <Text text="{i18n>firstNameLabelText}"/>
                                </Column>
                                <Column id="lastNameColumn">
                                    <Text text="{i18n>lastNameLabelText}"/>
                                </Column>
                                <Column id="ageColumn">
                                    <Text text="{i18n>ageLabelText}"/>
                                </Column>
                            </columns>
                            <items>
                                <ColumnListItem>
                                    <cells>
                                        <Input value="{UserName}"/>
                                    </cells>
                                    <cells>
                                        <Input value="{FirstName}"/>
                                    </cells>
                                    <cells>
                                        <Input value="{LastName}"/>
                                    </cells>
                                    <cells>
                                        <Input value="{Age}"/>
                                    </cells>
                                </ColumnListItem>
                            </items>
                        </Table>
                    </content>
                </Page>
            </pages>
        </App>
    </Shell>
</mvc:View>
```

We add the `$count : true` parameter to tell the OData service to send the number of entities. With this setting, we automatically get the full number of entities (20) and the number of displayed entities (10) beneath the *More* button.

> **i Note**
>
> The live TripPin service does not support the `$count` parameter yet. If you use the live service instead of the mock server, as described in Step 2, leave out the `$count` parameter.

In the `OverflowToolbar`, we add a *Search* field and a *Sort* button with their events.

webapp/i18n/i18n.properties

```
...
#XTOL: Tooltip for refresh data
refreshButtonText=Refresh Data
#XTOL: Tooltip for sort
sortButtonText=Sort by Last Name
```

```
#XTXT: Placeholder text for search field
searchFieldPlaceholder=Type in a last name
...
# Messages
...
#XMSG: Message for refresh succeeded
refreshSuccessMessage=Data refreshed
#MSG: Message for sorting
sortMessage=Users sorted by {0}

#MSG: Suffix for sorting by LastName, ascending
sortAscending=last name, ascending

#MSG: Suffix for sorting by LastName, descending
sortDescending=last name, descending

#MSG: Suffix for no sorting
sortNone=the sequence on the server
```

We add the missing texts to the properties file.

Step 5: Batch Groups

In this step, we have a closer look at batch groups. Batch groups are used to group multiple requests into one server request to improve the overall performance.

Preview

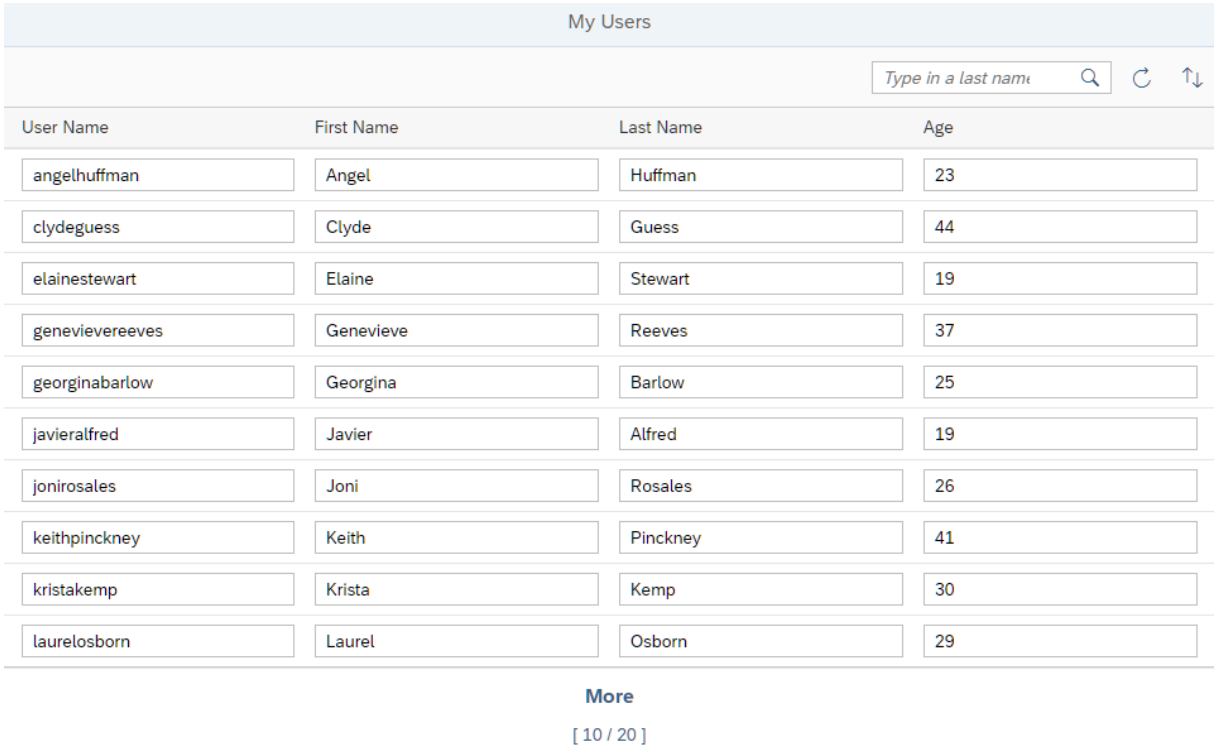

Figure 71: No visual change compared to the last step

Coding

You can view and download all files at OData V4 - Step 5.

webapp/manifest.json

```
...
                "": {
                "dataSource": "default",
                "settings": {
                    "autoExpandSelect": true,
                    "operationMode": "Server",
                    "groupId": "$auto",
                    "synchronizationMode": "None"
```

```
                    }
...
```

In the previous steps, batch processing was turned off, so that we could monitor the network traffic between our app and the service more easily. Now we turn on batch processing by changing the `groupID` to `$auto`. You can also just remove the line from the code as this is the default.

We now run the app and open the browser developer tools. On the *Console* tab, we clear all messages and choose the *Refresh* button.

> → Tip
>
> Change the settings of the *Console* so that it only displays information messages, not warnings and errors, to make it easier to find the messages we're looking for.

We see that the request is now bundled: To read the user data, the app now sends a `POST` request instead of a `GET` request to the server. The URL of the `POST` request does not include the `path` to the data we want. Instead it ends with `$batch` that indicates that this is a batch request.

A `$batch` request uses multipart MIME to put several requests into one. This makes it harder to analyze when looking at the request in the browser developer tools. To overcome this issue, you can:

- Switch the group ID to `$direct` temporarily by changing the source code or changing the default value in the debugger.
- Copy the relevant part of the request or response from the developer tools to an editor and auto-format it as JSON to analyze it.

Step 6: Create and Edit

In this step, we will make it possible to create and edit (update) user data from the user interface and send the data to the back end.

Preview

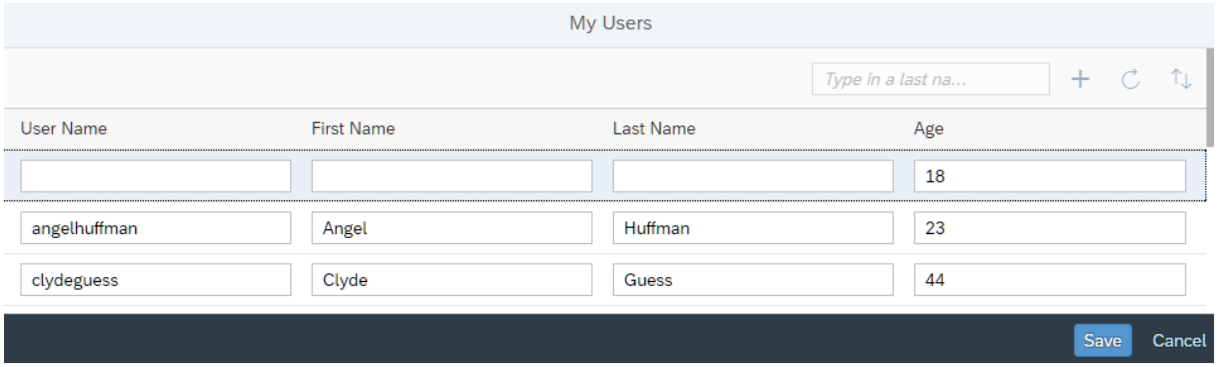

Figure 72: Data can now be edited and added.

Coding

You can view and download all files at OData V4 - Step 6.

webapp/controller/App.controller.js

```
...
        onInit : function () {
            var oMessageManager = sap.ui.getCore().getMessageManager(),
                oMessageModel = oMessageManager.getMessageModel(),
                oMessageModelBinding = oMessageModel.bindList("/", undefined, [],
                    new Filter("technical", FilterOperator.EQ, true)),
                oViewModel = new JSONModel({
                    busy : false,
                    hasUIChanges : false,
                    usernameEmpty : true,
                    order : 0
                });
            this.getView().setModel(oViewModel, "appView");
            this.getView().setModel(oMessageModel, "message");

            oMessageModelBinding.attachChange(this.onMessageBindingChange, this);
            this._bTechnicalErrors = false;
},
...
```

We change the `onInit` method: The `appView` model receives two additional properties, which we will use to control whether certain controls in the view are enabled or visible during user entries. We also make the `MessageModel` available to the view and add a `ListBinding`. When the OData service reports errors while

writing data, the OData Model adds them to the `MessageModel` as technical messages. Therefore we apply a filter to the `ListBinding`. We register our own handler to the `change` event of that `ListBinding` in order to capture any errors.

```
...
        onSort : function () {
            ...
        },
        _getText : function (sTextId, aArgs) {
            ...
        },
        _setUIChanges : function (bHasUIChanges) {
            if (this._bTechnicalErrors) {
                // If there is currently a technical error, then force 'true'.
                bHasUIChanges = true;
            } else if (bHasUIChanges === undefined) {
                bHasUIChanges = this.getView().getModel().hasPendingChanges();
            }
            var oModel = this.getView().getModel("appView");
            oModel.setProperty("/hasUIChanges", bHasUIChanges);
        }
    });
});
```

We add the `_setUIChanges` private method that lets us set the property `hasUIChanges` of the `appView` model. Unless there are currently technical messages in the `MessageModel` or it is called with a given value for its `bHasUIChanges` parameter, the method uses `ODataModel.hasPendingChanges`. That method returns `true` if there are any changes that have not yet been written to the service.

```
...
        onInit: function () {
            ...
        },
        onCreate : function () {
            var oList = this.byId("peopleList"),
                oBinding = oList.getBinding("items"),
                oContext = oBinding.create({
                    "UserName" : "",
                    "FirstName" : "",
                    "LastName" : "",
                    "Age" : "18"
                });

            this._setUIChanges();
            this.getView().getModel("appView").setProperty("/usernameEmpty",
true);

            oList.getItems().some(function (oItem) {
                if (oItem.getBindingContext() === oContext) {
                    oItem.focus();
                    oItem.setSelected(true);
                    return true;
                }
            });
        },
        onRefresh
...
```

We add the `onCreate` event handler that responds to the `press` event of the *Add User* button. We use the `create` method of the `ODataListBinding` API to create a new user with some initial data and insert it at the top of the table. The `create` method returns the binding context of the new user. That context provides a

`created` method which returns a `Promise`. The `Promise` is resolved when the new user is successfully transferred to the OData service.

We also use the binding context returned by the `create` method to focus and select the new row in which the new data can be entered.

```
...
        onRefresh: function () {
            ...
        },
        onSave : function () {
            var fnSuccess = function () {
                this._setBusy(false);
                MessageToast.show(this._getText("changesSentMessage"));
                this._setUIChanges(false);
            }.bind(this);

            var fnError = function (oError) {
                this._setBusy(false);
                this._setUIChanges(false);
                MessageBox.error(oError.message);
            }.bind(this);

            this._setBusy(true); // Lock UI until submitBatch is resolved.
            this.getView().getModel().submitBatch("peopleGroup").then(fnSuccess,
fnError);
            this._bTechnicalErrors = false; // If there were technical errors, a
new save resets them.
        },
        onSearch: function () {
            ...
        },
        ...
        _setUIChanges : function (bHasUIChanges) {
            ...
        },
        _setBusy : function (bIsBusy) {
            var oModel = this.getView().getModel("appView");
            oModel.setProperty("/busy", bIsBusy);
        }
    });
});
```

We create the `onSave` event handler, in which we call the `submitBatch` method of the `ODataModel` API to submit our changes. Because the changes that we submit refer to the table, we need to pass the update group `peopleGroup` that we declared in the table binding.

The `submitBatch` method returns a `Promise` that is rejected only if the batch request itself fails, for example, if the OData service is unavailable or if there were authorization problems. It is resolved in all other cases, also if the service returns errors for single requests that are contained in the batch request. Therefore, we have to implement the error handling for single requests differently.

We also define a `_setBusy` private function to lock the whole UI while the data is submitted to the back end.

```
...
        onSort : function () {
            ...
        },
        onMessageBindingChange : function (oEvent) {
            var aContexts = oEvent.getSource().getContexts(),
                aMessages,
                bMessageOpen = false;

            if (bMessageOpen || !aContexts.length) {
```

```
                return;
            }

            // Extract and remove the technical messages
            aMessages = aContexts.map(function (oContext) {
                return oContext.getObject();
            });
            sap.ui.getCore().getMessageManager().removeMessages(aMessages);

            this._setUIChanges(true);
            this._bTechnicalErrors = true;
            MessageBox.error(aMessages[0].message, {
                id : "serviceErrorMessageBox",
                onClose : function () {
                    bMessageOpen = false;
                }
            });

            bMessageOpen = true;
        },
...
```

We implement the event handler for the `change` event of the `ListBinding` to the `MessageModel`. We created the `ListBinding` with a filter to only include technical messages. That means that the `change` event will be fired with every change but only technical messages will have a binding context. In case of technical messages, we get the first one and display it as an error. We also make sure that the toolbar for saving or discarding changes stays visible. We delete the technical messages so that they do not accumulate.

```
...
        onRefresh: function () {
            ...
        },
        onResetChanges : function () {
            this.byId("peopleList").getBinding("items").resetChanges();
            this._bTechnicalErrors = false;
            this._setUIChanges();
        },
        onSearch: function () {
            ...
        },
...
```

The `onResetChanges` method handles discarding pending changes. It uses the `resetChanges` method of the `ODataListBinding` API to remove any such changes. Then it calls the `_setUIChanges` private method to enable the elements of the header toolbar again and hide the footer.

```
...
        onCreate: function () {
            ...
        },
        onInputChange : function (oEvt) {
            if (oEvt.getParameter("escPressed")) {
                this._setUIChanges();
            } else {
                this._setUIChanges(true);
                if
(oEvt.getSource().getParent().getBindingContext().getProperty("UserName")) {
                    this.getView().getModel("appView").setProperty("/
usernameEmpty", false);
                }
            }
        },
        onRefresh : function () {
            ...
```

```
        },
...
```

The `onInputChange` event handler manages entries in any of the `Input` fields and triggers updates to the `appView` model as needed. It does an extra check on the `UserName` field to make sure that users cannot be saved without a `UserName`. Otherwise the OData service would return errors because `UserName` is a mandatory field.

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.core.tutorial.odatav4.controller.App"
    displayBlock="true"
    xmlns="sap.m"

hasUIChanges}}"
                                        tooltip="{i18n>sortButtonText}"
                                        press=".onSort"/>
                                </content>
                            </OverflowToolbar>
                        </headerToolbar>
                        <columns>
                            <Column id="userNameColumn">
                                <Text text="{i18n>userNameLabelText}"/>
                            </Column>
                            <Column id="firstNameColumn">
                                <Text text="{i18n>firstNameLabelText}"/>
                            </Column>
                            <Column id="lastNameColumn">
                                <Text text="{i18n>lastNameLabelText}"/>
                            </Column>
                            <Column id="ageColumn">
                                <Text text="{i18n>ageLabelText}"/>
                            </Column>
                        </columns>
                        <items>
                            <ColumnListItem>
                                <cells>
                                    <Input
                                        value="{UserName}"
                                        valueLiveUpdate="true"
                                        liveChange=".onInputChange"/>
                                </cells>
                                <cells>
                                    <Input
                                        value="{FirstName}"
                                        liveChange=".onInputChange"/>
                                </cells>
                                <cells>
                                    <Input
                                        value="{LastName}"
                                        liveChange=".onInputChange"/>
                                </cells>
                                <cells>
                                    <Input
                                        value="{Age}"
                                        valueLiveUpdate="true"
                                        liveChange=".onInputChange"/>
                                </cells>
                            </ColumnListItem>
                        </items>
                    </Table>
                </content>
                <footer>
                    <Toolbar visible="{appView>/hasUIChanges}">
                        <ToolbarSpacer/>
                        <Button
                            id="saveButton"
                            type="Emphasized"
                            text="{i18n>saveButtonText}"
                            enabled="{= ${message>/}.length === 0 &amp;amp;&amp;
${appView>/usernameEmpty} === false }"
                            press=".onSave"/>
                        <Button
                            id="doneButton"
                            text="{i18n>cancelButtonText}"
                            press=".onResetChanges"/>
                    </Toolbar>
                </footer>
            </Page>
        </pages>
```

```
        </App>
    </Shell>
</mvc:View>
```

We add the `$$updateGroupId: 'peopleGroup'` parameter to the table. This means that changes in the table are not sent to the service immediately but instead are collected until we explicitly send them.

We add a new *Add User* button to the overflow toolbar in the table header, and define a footer toolbar that contains *Save* and *Cancel* buttons that we can display or hide through the `appView` model. We can disable the *Save* button separately, for example when a user enters invalid data.

Finally, we add the `liveChange="onInputChange"` event handler to the table cells to make it possible to react to user input. In addition, we set the `valueLiveUpdate` properties for the fields for `UserName` and `Age`. That makes sure that the SAPUI5 types validate the field content with each keystroke.

webapp/i18n/i18n.properties

```
# Toolbar
#XBUT: Button text for save
saveButtonText=Save

#XBUT: Button text for cancel
cancelButtonText=Cancel
#XTOL: Tooltip for sort
sortButtonText=Sort by Last Name
#XBUT: Button text for add user
createButtonText=Add User
...
# Messages
#XMSG: Message for user changes sent to the service
changesSentMessage=User data sent to the server
...
```

We add the new message texts.

Step 7: Delete

In this step, we make it possible to delete user data.

Preview

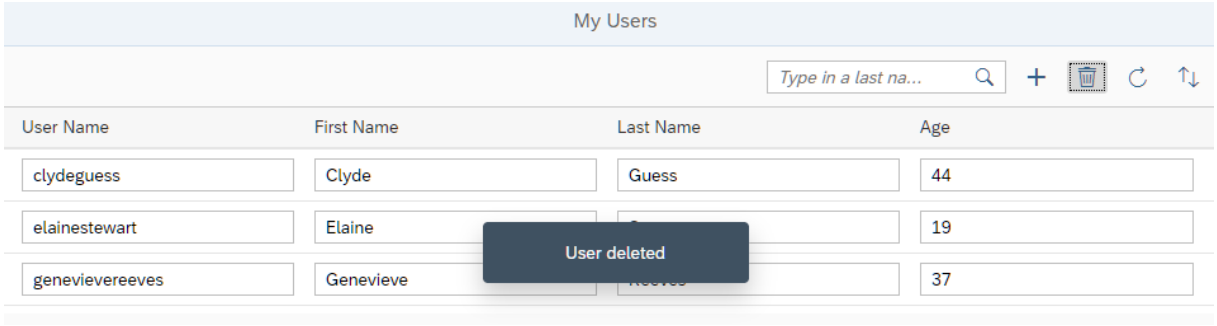

Figure 73: A new *Delete User* button is added

Coding

You can view and download all files at OData V4 - Step 7.

webapp/App.controller.js

```
        onDelete : function () {
            var oSelected = this.byId("peopleList").getSelectedItem();

            if (oSelected) {
                oSelected.getBindingContext().delete("$auto").then(function () {
                    MessageToast.show(this._getText("deletionSuccessMessage"));
                }.bind(this), function (oError) {
                    MessageBox.error(oError.message);
                });
            }
        },
```

We add the `onDelete` event handler to the controller. In the event handler, we check whether an item is selected in the table and if so, the related data is deleted from the model. To do that, we retrieve the binding context of the selection and call its `delete` method.

We explicitly set the update group ID for the deletion to `$auto` to make sure that the request to the service is sent immediately as a batch request. Otherwise the `delete` function would apply the deferred batch processing that we defined for the table's list binding event though, `delete` does not currently support deferred batch processing.

webapp/App.view.xml

```
<mvc:View
    controllerName="sap.ui.core.tutorial.odatav4.controller.App"
    displayBlock="true"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Shell>
        <App busy="{appView>/busy}" class="sapUiSizeCompact">
            <pages>
                <Page title="{i18n>peoplePageTitle}">
                    <content>
                        <Table
                            id="peopleList"
                            growing="true"
                            growingThreshold="10"
                            items="{
                                path: '/People',
                                parameters: {
                                    $count: true,
                                    $$updateGroupId : 'peopleGroup'
                                }
                            }"
                            mode="SingleSelectLeft">
                            <headerToolbar>
                                <OverflowToolbar>
                                    <content>
                                        <ToolbarSpacer/>
                                        <SearchField
                                        .../>
                                        <Button
                                        .../>
                                        <Button
                                            id="deleteUserButton"
                                            icon="sap-icon://delete"
                                            tooltip="{i18n>deleteButtonText}"
                                            press=".onDelete">
                                            <layoutData>
                                                <OverflowToolbarLayoutData
priority="NeverOverflow"/>
                                            </layoutData>
                                        </Button>
                                        <Button
                                        .../>
                                        <Button
                                        ...>
                                    </content>
                                </OverflowToolbar>
                            </headerToolbar>
                            <columns>
                                ...
                            </columns>
                            <items>
                                ...
                            </items>
                        </Table>
                    </content>
                    <footer>
                        ...
                    </footer>
                </Page>
            </pages>
        </App>
    </Shell>
</mvc:View>
```

We change the `mode` of the table to `SingleSelectLeft` to make it possible to select a row.

We add the *Delete* button to the toolbar. With the `OverflowToolbarLayoutData priority="NeverOverflow"` parameter, we make sure that the button is always visible.

webapp/i18n/i18n.properties

```
...
# Toolbar
...
#XBUT: Button text for delete user
deleteButtonText=Delete User
...
# Messages
...
#XMSG: Message for user deleted
deletionSuccessMessage=User deleted
...
```

We add the missing texts to the properties file.

Deleting an Entity [page 976]

Step 8: OData Operations

Our OData service provides one OData operation: the `ResetDataSource` action. In this step, we add a button that resets all data changes we made during the tutorial to their original state using this action.

Preview

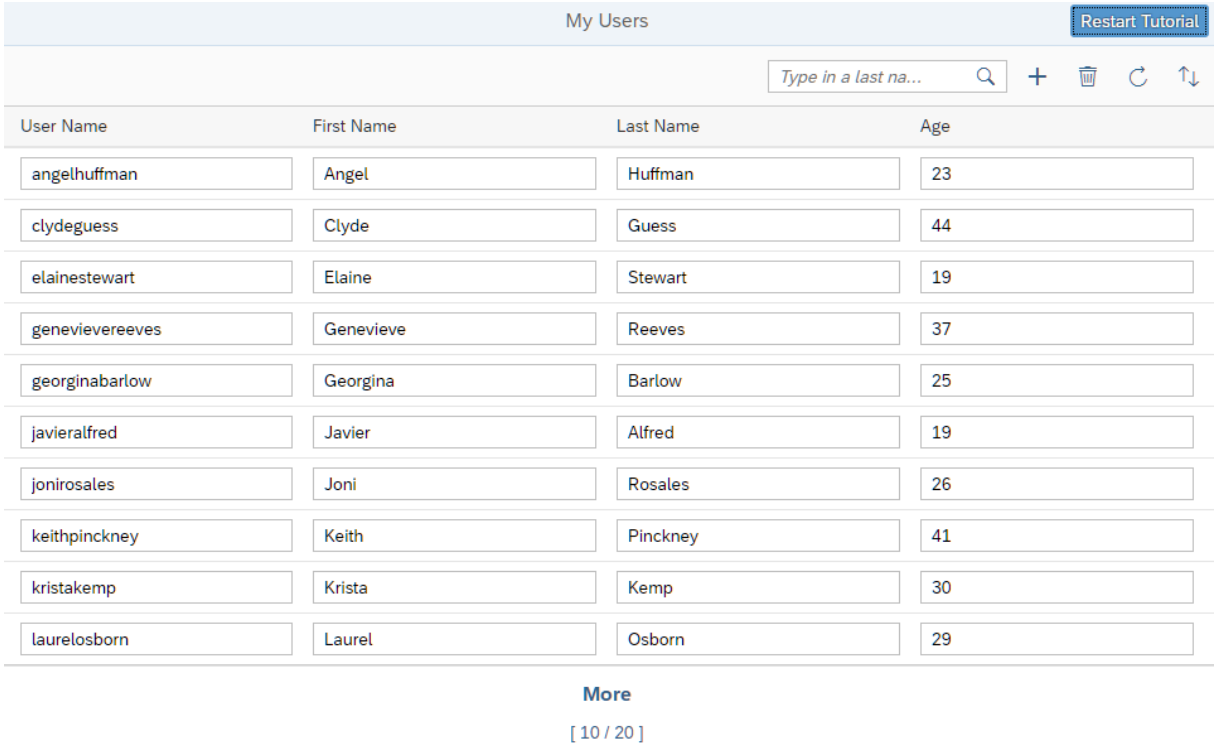

Figure 74: A *Restart Tutorial* button is added

Coding

You can view and download all files at OData V4 - Step 8.

webapp/controller/App.controller.js

```
...
        onResetChanges : function () {
            this.byId("peopleList").getBinding("items").resetChanges();
            this._setUIChanges();
        },
        onResetDataSource : function () {
            var oModel = this.getView().getModel(),
                oOperation = oModel.bindContext("/ResetDataSource(...)");
```

```
            oOperation.execute().then(function () {
                    oModel.refresh();

MessageToast.show(this._getText("sourceResetSuccessMessage"));
                }.bind(this), function (oError) {
                    MessageBox.error(oError.message);
                }
            );
        },
        onSave : function () {
...
```

The `onResetDataSource` event handler calls the `ResetDataSource` action, which is an action of the *TripPin* OData service that resets the data of the service to its original state.

We call that action by first creating a deferred operation binding on the model. The `(...)` part of the binding syntax marks the binding as deferred. We use a deferred binding because we want to control when the action is executed. Since it is deferred, we need to explicitly call its `execute` method.

The execution is asynchronous, therefore the execute method returns a `Promise`. We attach simple success and error handlers to that `Promise` by calling its `then` method.

> **i** Note
>
> Many of the methods in the OData V4 API of SAPUI5 return a `Promise` to manage asynchronous processing

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.core.tutorial.odatav4.controller.App"
    displayBlock="true"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Shell>
        <App busy="{appView>/busy}" class="sapUiSizeCompact">
            <pages>
                <Page title="{i18n>peoplePageTitle}">
                    <headerContent>
                        <Button
                            id="resetChangesButton"
                            text="{i18n>resetChangesButtonText}"
                            enabled="{= !${appView>/hasUIChanges}}"
                            press="onResetDataSource"
                            type="Emphasized">
                        </Button>
                    </headerContent>
...
```

We add the **headerContent** aggregation to the **Page** and insert the new **Button**. We add the **onResetDataSource** event handler to the **press** event.

webapp/i18n/i18n.properties

```
...
# Toolbar
...
#XBUT: Button text for reset changes
resetChangesButtonText=Restart Tutorial
...
# Messages
...
#XMSG: Message for changes reverted
sourceResetSuccessMessage=All changes reverted back to start
```

We add the missing texts to the properties file.

And now we are done! We built a simple application with user data from an OData V4 service. We can display, edit, create, and delete users. And we use OData V4 features such as batch groups and automatic type detection.

Navigation and Routing

SAPUI5 comes with a powerful routing API that helps you control the state of your application efficiently. This tutorial will illustrate all major features and APIs related to navigation and routing in SAPUI5 apps by creating a simple and easy to understand mobile app. It represents a set of best practices for applying the navigation and routing features of SAPUI5 to your applications.

In classical Web applications, the server determines which resource is requested based on the URL pattern of the request and serves it accordingly. The server-side logic controls how the requested resource or page is displayed in an appropriate way.

In single-page applications, only one page is initially requested from the server and additional resources are dynamically loaded using client-side logic. The user only navigates within this page. The navigation is persisted in the hash instead of the server path or URL parameters.

For example, a classical Web application might display the employee's resume page when URL `http://<your-host>/<some-path-to-the-app>/employees/resume.html?id=3` or `http://<your-host>/<some-path-to-the-app>/employees/3/resume` is called. A single-page application instead would do the same thing by using a hash-based URL like `http://<your-host>/<some-path-to-the-app>/#/employees/3/resume`.

The information in the hash, namely everything that is following the `#` character, is interpreted by the router.

i Note

This tutorial does not handle cross-app navigation with the SAP Fiori launchpad. However, the concepts described in this tutorial are also fundamental for navigation and routing between apps in the SAP Fiori launchpad.

We will create a simple app displaying the data of a company's employees to show typical navigation patterns and routing features. The complete flow of the application can be seen in the figure below. We'll start with the home page which lets users do the following:

- Display a *Not Found* page
- Navigate to a list of employees and drill further down to see a *Details* page for each employee
- Show an *Employee Overview* that they can search and sort

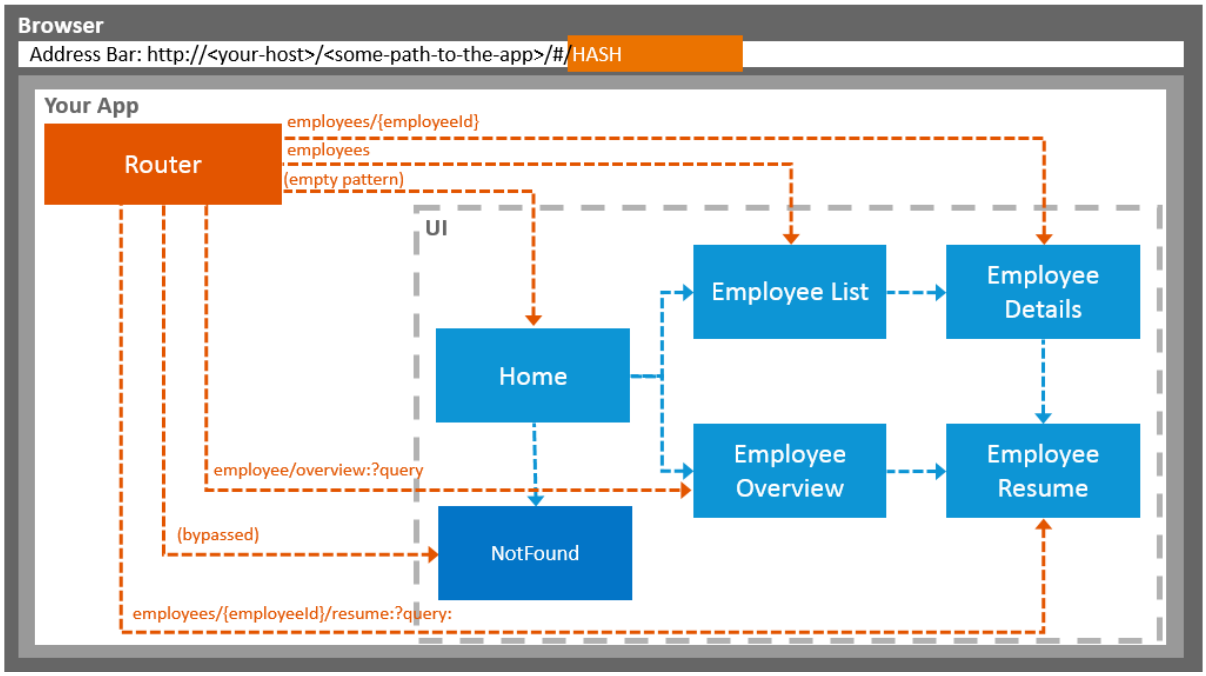

Figure 75: Page flow of the final app

Throughout this tutorial we will add features for navigating to pages and bookmarking them. We will add backward and forward navigation with common transition animations (slide, show, flip, etc.). We will add more pages to the app and navigate between them to show typical use cases. We will even learn how to implement features for bookmarking a specific search, table sorting via filters, and dialogs.

→ Tip

You don't have to do all tutorial steps sequentially, you can also jump directly to any step you want. Just download the code from the previous step, and start there.

You can view and download the files for all steps in the Demo Kit at Navigation and Routing. Copy the code to your workspace and make sure that the application runs by calling the `webapp/index.html` file. Depending on your development environment you might have to adjust resource paths and configuration entries.

For more information check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]

Step 1: Set Up the Initial App

We start by setting up a simple app for this tutorial. The app displays mock data only and mimics real OData back-end calls with the mock server as you have seen in the *Walkthrough* tutorial.

The structure and data model created in this step will be used throughout the rest of this tutorial. The initial app created in this step will be extended in the subsequent steps to illustrate the navigation and routing features of SAPUI5.

Preview

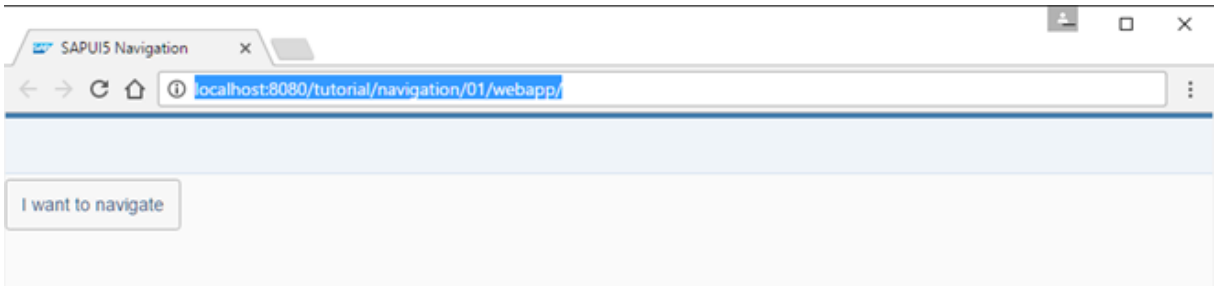

Figure 76: Initial app with a simple button

Setup

To set up your project for this tutorial, download the files for *Step 1* from the *Samples* in the Demo Kit at Navigation and Routing - Step 1. Copy the code to your workspace and make sure that the application runs by calling the `webapp/index.html` file.

Depending on your development environment you might have to adjust resource paths and configuration entries. The project structure and the files coming with this tutorial are explained in detail in the Walkthrough [page 69] tutorial.

You should have the same files as displayed in the following figure:

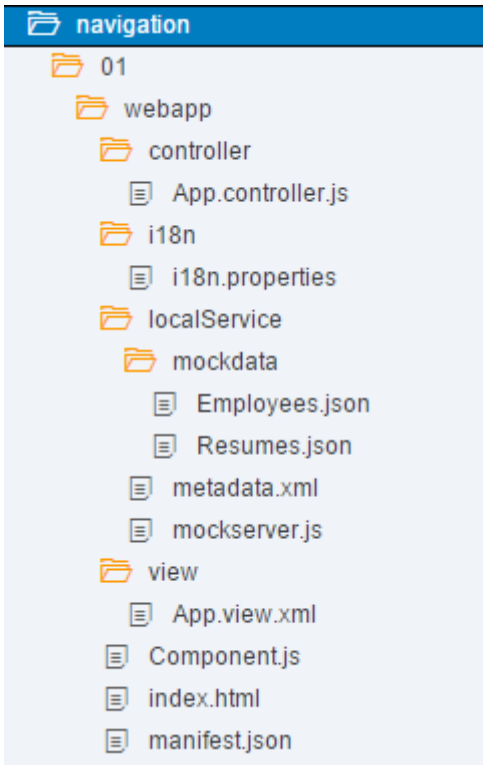

Figure 77: Folder structure with downloaded files

> **i** Note
>
> The content of the `localService` folders will not be changed in this tutorial. The `i18n` folder will always contain the `i18n.properties` file only. Therefore, we will show both subfolders collapsed in the following steps.

The Initial App

With the downloaded coding, you have an initial app with recommended settings that provides the basic features of an SAPUI5 app:

- **Home Page**
  The home page of our app is defined in the `webapp/index.html` file. In this file we bootstrap SAPUI5 and tell the runtime where to find our custom resources. Furthermore, we initialize the `MockServer` to simulate back-end requests as we do not have a real back-end service throughout this tutorial. Finally, we instantiate the application component, assign it to a `sap.m.Shell` control, and place the shell into the body. The corresponding `Component.js` file in the `webapp` folder will be extended throughout this tutorial.
- **Data**
  In the `webapp/localService/mockserver.js` file, we configure the mock server. Using the mock server in this tutorial allows us to easily run the code even without network connection and without the need of having a remote server for our application data.

The `metadata.xml` file used by the mock server describes our OData service. The service only has two OData entities:

- Employee
  An `employee` has typical properties like `FirstName` and `LastName` as well as a navigation property to a resume entity referenced by a `ResumeID`. Of course, the entity also has an ID property: `EmployeeID`. The corresponding `EntitySet` is `Employees`. The actual test data containing several employees is located in the `webapp/localService/mockdata/Employees.json` file.
- Resume
  In our case, we want to keep the resume of employees very simple. Therefore, we just have simple properties of type `Edm.String`. The properties are `Information`, `Projects`, `Hobbies` and `Notes`; all of them contain textual information. The entity has an ID property `ResumeID` and the corresponding `EntitySet` is `Resumes`. The resume data for an employee is located in file `webapp/localService/mockdata/Resumes.json`.

- **Configuration of the App**
  In the `webapp/manifest.json` descriptor file, we configure our app. The descriptor file contains the following most interesting sections:
  - `sap.app`
    In this section we reference an `i18n.properties` file and use a special syntax to bind the texts for the `title` and `description` properties.
    In the `dataSources` part, we tell our app where to find our OData service `employeeRemote`. As you might guess, the `uri` correlates to the `rootUri` of our mock server instance which can be found in `webapp/localService/mockserver.js`. It is important that these two paths match to allow our mock server to provide the test data we defined above. The `localUri` is used to determine the location of the `metadata.xml` file.
  - `sap.ui5`
    Under `sap.ui5` we declare with the `rootView` parameter that our `sap.ui.demo.nav.view.App` view shall be loaded and used as the `rootView` for our app. Furthermore, we define two `models` to be automatically instantiated and bound to the `i18n` component and a default model `""`. The latter references our `employeeRemote dataSource` which is declared in our `sap.app` section as an OData 2.0 data source. The `i18n` file can be found at `webapp/i18n/i18n.properties`. This data source will be mocked by our mock server.

So far we have a basic app that does not really have any navigation or routing implemented. This will change in the next steps when we implement our first navigation features.

Step 2: Enable Routing

In this step we will modify the app and introduce routing. Instead of having the home page of the app hard coded we will configure a router to wire multiple views together when our app is called. The routing

configuration controls the application flow when the user triggers a navigation action or opens a link to the application directly.

Preview

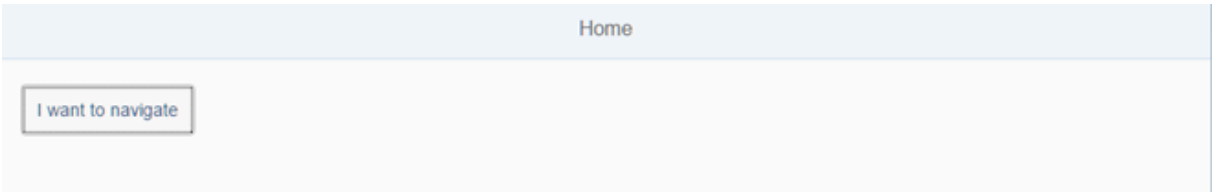

Figure 78: Views are wired together using the router

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 2.

                    "viewName": "Home",
                    "viewLevel" : 1
                }
            }
        }
    }
}
```

Single-page applications based on SAPUI5 can use a so-called “router” to dispatch hash-based URLs to one or more views of the app. Therefore, the router needs to know how to address and show the views. In SAPUI5, we can simply add a `routing` section to our existing `sap.ui5` section in the descriptor file to configure the router. There are three properties that can be used to configure the routing of your application:

- `config`
  This section contains the global router configuration and default values that apply for all routes and targets. The property `routerClass` is special as it determines the router implementation. The default value is `sap.ui.core.routing.Router`. Here, we set the `routerClass` to `sap.m.routing.Router`, because we implement an app based on `sap.m`. All other properties in `config` are given to the router instance. For example, we define where our views are located in the app. To load and display views automatically, we also specify the `controlId` of the control that is used to display the pages and the aggregation (`controlAggregation`) that will be filled when a new page is displayed. We will create only XMLviews in this tutorial, so we can set the `viewType` property to `XML`. All our views will be available in the `view` folder of the namespace `sap.ui.demo.nav`, so we can set the `viewPath` to `sap.ui.demo.nav.view`. The `transition` allows us to set a default value for how the transition should happen; you can choose between `slide` (default), `flip`, `fade`, and `show`. All parameters of the config section can be overruled in the individual route and target definitions if needed.

  > **i Note**
  >
  > The possible values for `routerClass` are `sap.ui.core.routing.Router`, `sap.m.routing.Router`, or any other subclasses of `sap.ui.core.routing.Router`. Compared to `sap.ui.core.routing.Router` the `sap.m.routing.Router` is optimized for mobile apps and adds the properties `viewLevel`, `transition` and `transitionParameters` which can be specified

for each route or target created by the `sap.m.routing.Router`. The `transitionParameters` can also be used for custom transitions. Please check the *API Reference* for more information.

- `routes`
  Each route defines a name, a pattern, and one or more targets to navigate to when the route has been hit. The pattern is basically the hash part of the URL that matches the route. The sequence of the routes is important because only the first matched route is used by the router. In our case, we have an empty pattern to match the empty hash. The `name` property allows you to choose a unique route name that helps you to navigate a specific route or to determine the matched route in one of the matched handlers (we'll explain that in a later step). The target property references one or more targets from the section below that will be displayed when the route has been matched.
- `targets`
  A target defines the view that is displayed. It is associated with one or more routes or it can be displayed manually from within the app. Whenever a target is displayed, the corresponding view is loaded and added to the aggregation configured with the `controlAggregation` option of the control. This option is configured using `controlId`. Each target has a unique key (`home`). The `viewName` defines which view shall be loaded. In our little example, the absolute view path to be loaded for our `home` target is determined by the default `"viewPath": "sap.ui.demo.nav.view"` and `"viewName": "Home"`. This leads to `"sap.ui.demo.nav.view.Home"`. The `viewLevel` is especially relevant for `flip` and `slide` transitions. It helps the router to determine the direction of the transition from one page to another. (This will also be explained later.) A target can be assigned to a route, but it's not necessary. Targets can be displayed directly in the app without hitting a route.
  This basic routing configuration was easy enough. However, you can't see it in action until you have initialized the router.

> **i Note**
>
> As of SAPUI5 version 1.30, we recommend that you define the routing in the `manifest.json` descriptor file using routes and targets. In older versions of SAPUI5, the routing configuration had to be done directly in the metadata section of the component, and with different syntax.

webapp/Component.js

```
sap.ui.define([
    "sap/ui/core/UIComponent"
], function (UIComponent) {
    "use strict";
    return UIComponent.extend("sap.ui.demo.nav.Component", {
        metadata: {
            manifest: "json"
        },

        init: function () {
            // call the init function of the parent
            UIComponent.prototype.init.apply(this, arguments);

            // create the views based on the url/hash
            this.getRouter().initialize();
        }
    });
});
```

We override the `init` function and call the parent's `init` function first. We get a reference to the router and call `initialize()` on it. The router is instantiated automatically with the configuration loaded in the descriptor. The routing events and our configuration in the descriptor are now automatically enabled in the app. Running the app at this point would lead to an error, because the home view is not implemented yet.

webapp/view/App.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    displayBlock="true">
    <Shell>
        <App id="app"/>
    </Shell>
</mvc:View>
```

In the `App` view, we remove the content of `App` control. The pages will be added dynamically the way we have configured it in the descriptor. The view configured with the property `rootView` is automatically instantiated when the app is called initially.

webapp/view/Home.view.xml (New)

```
<mvc:View
   controllerName="sap.ui.demo.nav.controller.Home"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <Page title="{i18n>homePageTitle}" class="sapUiResponsiveContentPadding">
      <content>
         <Button text="{i18n>iWantToNavigate}" class="sapUiTinyMarginEnd"/>
      </content>
   </Page>
</mvc:View>
```

Create a file `Home.view.xml` in the `webapp/view` folder. The home view only contains a page control that displays a button. For illustration, we bind the title of the page to the `i18n>homePageTitle`, you can use data binding just the way you are used to it.

webapp/controller/Home.controller.js (New)

```
sap.ui.define([
   "sap/ui/core/mvc/Controller"
], function (Controller) {
   "use strict";

   return Controller.extend("sap.ui.demo.nav.controller.Home", {

   });
```

```
});
```

Create a file `Home.controller.js` in the `webapp/controller` folder. The controller for the home view does not contain any custom logic in this step, but we will add some features to it soon. Finally, run the app by calling the `webapp/index.html` file. This will be the entry point for our app in all the next steps. As you can see, the app is initially displaying the home view that we configured as the default pattern in the routing configuration. We have now successfully enabled routing in the app.

> **i** Note
>
> We think of routing as a set of features that dispatch hash-based URLs to an app's views and manage the views' states.
>
> Based on the routing configuration, you define the navigation between pages and pass parameters to the target views.

Conventions

- Configure the router in the `manifest.json` descriptor file
- Initialize the router exactly once
- Initialize the router in the component

Step 3: Catch Invalid Hashes

Sometimes it is important to display an indication that the requested resource was not found. To give you an example: If a user tries to access an invalid pattern which does not match any of the configured routes, the user is notified that something went wrong. You might also know this as a “404” or *Not Found Page* from traditional web pages. In this step, we will implement a feature that detects invalid hashes and visualizes this in a nice way.

Preview

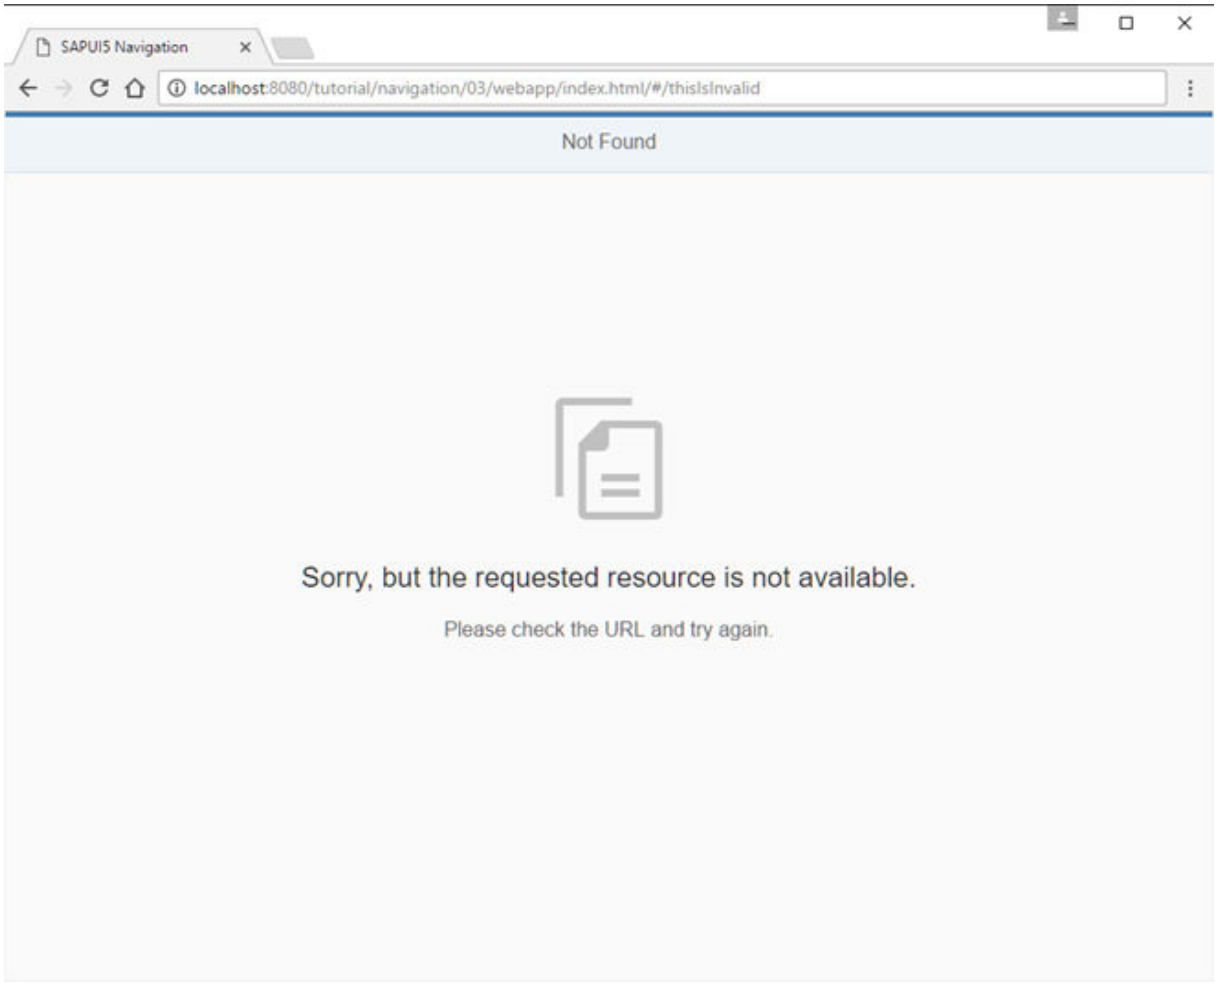

Figure 80: *Not Found* page

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 3.

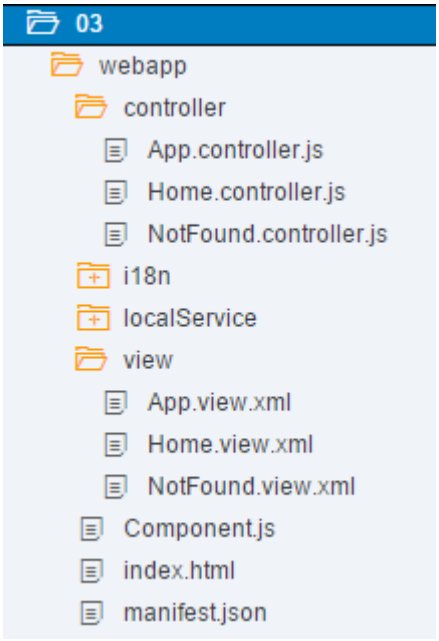

Figure 81: Folder structure for this step

webapp/manifest.json

```
{
   ...
   "sap.ui5": {
      ...
      "routing": {
         "config": {
            "routerClass": "sap.m.routing.Router",
            "viewType": "XML",
            "viewPath": "sap.ui.demo.nav.view",
            "controlId": "app",
            "controlAggregation": "pages",
            "transition": "slide",
            "bypassed": {
               "target": "notFound"
            },
            "async": true
         },
         "routes": [{
            "pattern": "",
            "name": "appHome",
            "target": "home"
         }],
         "targets": {
            "home": {
               "viewId": "home",
               "viewName": "Home",
               "viewLevel" : 1
            },
            "notFound": {
               "viewId": "notFound",
               "viewName": "NotFound",
               "transition": "show"
            }
         }
      }
   }
```

```
}
```

Let's extend the routing configuration in the descriptor by adding a `bypassed` property and setting its `target` to `notFound`. This configuration tells the router to display the `notFound` target in case no route was matched to the current hash. Next, we add a `notFound` target to the `bypassed` section. The `notFound` target simply configures a `notFound` view with a `show` transition.

webapp/view/NotFound.view.xml (New)

```
<mvc:View
   controllerName="sap.ui.demo.nav.controller.NotFound"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <MessagePage
      title="{i18n>NotFound}"
      text="{i18n>NotFound.text}"
      description="{i18n>NotFound.description}"/>
</mvc:View>
```

Now we create the view referenced above in a new file `NotFound.view.xml` in the `webapp/view folder`. It uses a `sap.m.MessagePage` control to display an error message to the user. In a real app you might use a dynamic message matching the current error situation. Here, we simply display a preconfigured text from our resource bundle.

webapp/controller/NotFound.controller.js (New)

```
sap.ui.define([
   "sap/ui/core/mvc/Controller"
], function (Controller) {
   "use strict";
   return Controller.extend("sap.ui.demo.nav.controller.NotFound", {
      onInit: function () {
      }
   });
});
```

Now we create the controller for the `NotFound` view and save it into the `webapp/controller` folder. This controller will be extended later.

webapp/i18n/i18n.properties

```
...
NotFound=Not Found
NotFound.text=Sorry, but the requested resource is not available.
NotFound.description=Please check the URL and try again.
```

Add the new properties to the `i18n.properties` file.

Open the URL `index.html#/thisIsInvalid` in your browser. From now on the user will see a nice *Not Found* page if a hash could not be matched to one of our routes.

Conventions

- Always configure the `bypassed` property and a corresponding target
- Use the `sap.m.MessagePage` control to display routing related error messages

API Reference: `sap.m.MessagePage`
API Overview and Samples: `sap.m.MessagePage`

Step 4: Add a *Back* Button to *Not Found* Page

When we are on the *Not Found* page because of an invalid hash, we want to get back to our app to select another page. Therefore, we will add a *Back* button to the *Not Found* view and make sure that the user gets redirected to either the previous page or the overview page when the *Back* button is pressed.

Preview

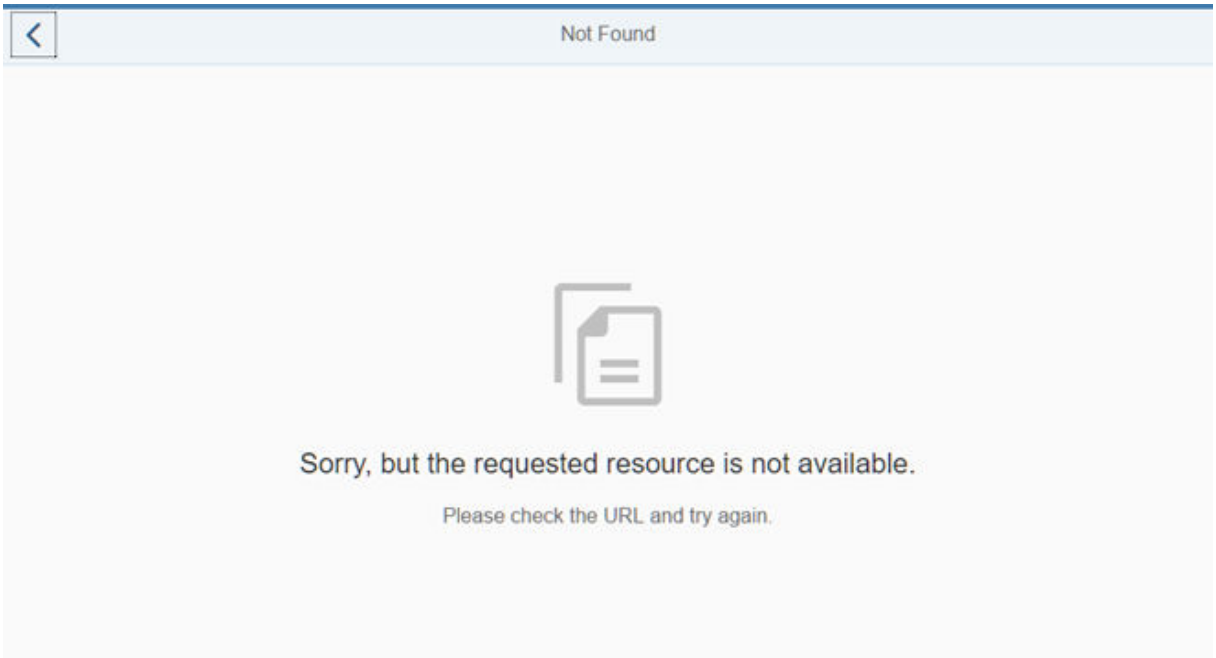

Figure 82: *Not Found* page with *Back* button

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 4.

webapp/view/NotFound.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.NotFound"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <MessagePage
        title="{i18n>NotFound}"
        text="{i18n>NotFound.text}"
        description="{i18n>NotFound.description}"
        showNavButton="true"
        navButtonPress="onNavBack"/>
</mvc:View>
```

In the `NotFound` view, we set the property `showNavButton` of the `MessagePage` control to `true` to automatically display the *Back* button. We also add an event handler function `onNavBack` to the `navButtonPress` event of the control. The `onNavBack` function will handle the actual back navigation. We could directly add this function to the view's controller. However, we are smart enough to anticipate that we might need the same handler function for different views. DRY ("Don't Repeat Yourself") is the right approach for us, so let's create a `BaseController` from which all other controllers will inherit.

webapp/controller/BaseController.js (New)

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/core/routing/History",
    "sap/ui/core/UIComponent"
], function(Controller, History, UIComponent) {
    "use strict";

    return Controller.extend("sap.ui.demo.nav.controller.BaseController", {

        getRouter : function () {
            return UIComponent.getRouterFor(this);
        },

        onNavBack: function () {
            var oHistory, sPreviousHash;

            oHistory = History.getInstance();
            sPreviousHash = oHistory.getPreviousHash();

            if (sPreviousHash !== undefined) {
                window.history.go(-1);
            } else {
                this.getRouter().navTo("appHome", {}, true /*no history*/);
            }
        }

    });

});
```

Create a new `BaseController.js` file in the `webapp/controller` folder. The base controller implements a set of functions that are reused by its subclasses. The `onNavBack` handler is a great example of code that we don't want to duplicate in our controllers for each page that has a back navigation.

The function checks if there is a previous hash value in the app history. If so, it redirects to the previous hash via the browser's native `History` API. In case there is no previous hash we simply use the router to navigate to the route `appHome` which is our home view.

The third parameter of `navTo("appHome", {}, true /*no history*/);` has the value `true` and makes sure that the hash is replaced. With the line `sap.ui.core.UIComponent.getRouterFor(this)` you can easily access your component's router throughout the app. To make it even more comfortable, we also add a handy shortcut `getRouter` to the base controller. This function is now available in each subclass as well. It is also used in the `onNavBack` handler to get a reference to the router before calling `navTo`. We now have to implement the reuse in all other controllers.

> **i Note**
>
> In SAPUI5 there are multiple options to reuse code. We recommend to use a base controller for such helper methods because this allows us to decoratively use the `onNavBack` handler directly in any XML view without adding additional code to the controller. Our base controller is an abstract controller that will not be instantiated in any view. Therefore, the naming convention `*.controller.js` does not apply, and we can just call the file `BaseController.js`. By not using the naming convention `*.controller.js` we can even prevent any usage in views.

webapp/controller/NotFound.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.NotFound", {
        onInit: function () {
        }
    });
});
```

In order to reuse the base controller implementation, we have to change the dependency from `sap/ui/core/mvc/Controller` to `sap/ui/demo/nav/controller/BaseController` and directly extend the base controller.

At this point you can open `index.html#/thisIsInvalid` in your browser and press the *Back* button to see what happens. You will be redirected to the app's home page that is matched by the route `appHome` as you opened the *Not Found* page with an invalid hash. If you change the hash to something invalid when you are on the home page of the app, you will also go to the *Not Found* page but with a history entry. When you press back, you will get to the home page again, but this time with a native history navigation.

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.App", {
        onInit: function () {
        }
    });
});
```

To be consistent, we will now extend all of our controllers with the base controller. Change the app controller as described above.

webapp/controller/Home.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.Home", {
    });
});
```

The same applies to our home controller, we also extend it with the base controller now.

> **i** Note
>
> In this step we have added the *Back* button. The user can always use the browser's native *Back* button as well. Each app can freely configure the behavior of the *Back* button. However, there is no clean way to apply the same logic for the browser's *Back* button in single-page applications. Tweaking the browser history or using other quirks for cancelling backward or forward navigation is not recommended due to the implementation details of the browsers. The browser's *Back* button always uses the browser history while the *Back* button of the app can make use of the browser history **or** can implement its own navigation logic. Make sure to understand this difference and only control the *Back* button inside the app.

Conventions

- Implement a global `onNavBack` handler for back navigation in your app
- Query the history and go to the home page if there is no history available for the current app

Related Information

Routing and Navigation [page 1072]

Step 5: Display a Target Without Changing the Hash

In this step, you will learn more about targets and how to display a target from the routing configuration manually.

We will display the *Not Found* target from the previous step without changing the hash to illustrate this navigation pattern. We will also consider a side-effect that prevents us from navigating back in this case.

Fortunately, we can extend our app and offer an easy solution. There are some use cases that should not be persisted in the URL but just be triggered by the application logic if needed. A target is a navigation-related configuration for a view and we can display targets manually without referencing them in a navigation route. Good examples for this are temporary errors, switching to an edit page for a business object, or going to a *Settings* page. Sometimes you will also have to implement a way back manually.

Preview

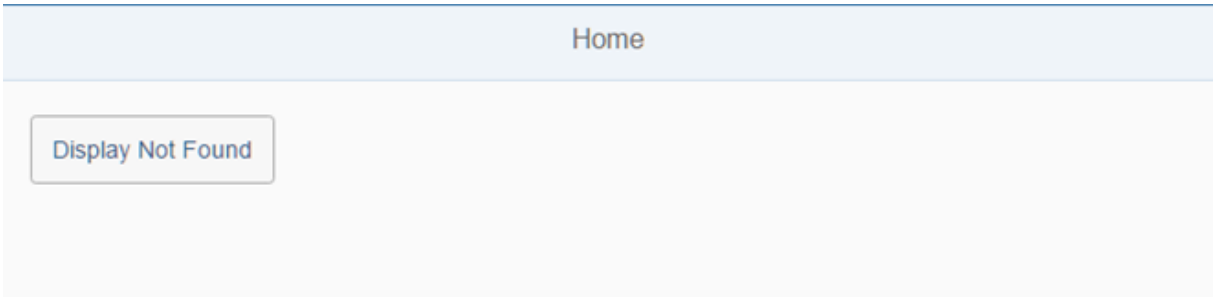

Figure 83: The new *Home* page with a navigation button

Coding

You can view and download all files in the *Samples* in the Demo -kit at Routing and Navigation - Step 5.

webapp/view/Home.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.Home"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page title="{i18n>homePageTitle}" class="sapUiResponsiveContentPadding">
        <content>
            <Button id="displayNotFoundBtn" text="{i18n>DisplayNotFound}"
press=".onDisplayNotFound" class="sapUiTinyMarginEnd"/>
        </content>
    </Page>
</mvc:View>
```

We start by changing the `Button` control from the home view. When the button is pressed, the `onDisplayNotFound` handler is called.

webapp/controller/Home.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.Home", {
        onDisplayNotFound : function () {
            //display the "notFound" target without changing the hash
            this.getRouter().getTargets().display("notFound");
        }
    });
});
```

Inside the `onDisplayNotFound` handler we get a reference to the `Targets` helper object of the router and simply call `display("notFound")`. The view associated to the target with the name `notFound` from the routing configuration will be displayed by the router without changing the hash.

The `sap.m.routing.Targets` object itself can be retrieved by calling `getTargets()` on the router. It provides a convenient way for placing views into the correct containers of your application. The main benefits of targets are structuring and lazy loading: you just configure the views in the routing configuration and you do not have to load the views until you really need them.

> **i Note**
>
> In the example code we get a reference to the `sap.m.routing.Targets` object by calling `getTargets()` on `this.getRouter()` from the base controller. However, you could also get a reference to the `sap.m.routing.Targets` object by calling `this.getOwnerComponent().getRouter().getTargets()` or `this.getOwnerComponent().getTargets()`.

If you now call the app and press the *Display Not Found* button you see that the `notFound` target is displayed without changing the URL. That was easy, but suddenly our app's *Back* button does not work anymore. The bug we have just introduced illustrates an interesting navigation trap. The application hash is still empty since we just display the target and did not hit a route.

When pressing the app's *Back* button, the `onNavBack` from the previous step is called. It detects that there is no previous hash and therefore tries to navigate to the `appHome` route again. The router is smart enough to detect that the current hash did not change and therefore skips the navigation to the route. Fortunately, there is an easy workaround for us. However, we need to touch the `Home` controller again.

webapp/controller/Home.controller.js (Changed Again)

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.Home", {
        onDisplayNotFound : function () {
            //display the "notFound" target without changing the hash
            this.getRouter().getTargets().display("notFound", {
                fromTarget : "home"
            });
        }
    });
});
```

This time we pass on a data object as the second parameter for the display method which contains the name of the current target; the one from which we navigate to the `notFound` target. We decide to choose the key `fromTarget` but since it is a custom configuration object any other key would be fine as well.

webapp/controller/NotFound.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.NotFound", {
        onInit: function () {
            var oRouter, oTarget;

            oRouter = this.getRouter();
            oTarget = oRouter.getTarget("notFound");
            oTarget.attachDisplay(function (oEvent) {
                this._oData = oEvent.getParameter("data");    // store the data
            }, this);
        },

        // override the parent's onNavBack (inherited from BaseController)
        onNavBack : function () {
            // in some cases we could display a certain target when the back
button is pressed
            if (this._oData && this._oData.fromTarget) {
                this.getRouter().getTargets().display(this._oData.fromTarget);
                delete this._oData.fromTarget;
                return;
            }

            // call the parent's onNavBack
            BaseController.prototype.onNavBack.apply(this, arguments);
        }
    });
});
```

Next, we have to register an event listener to the `display` event of the `notFound` target. The best place for us to register an event listener for this is inside the `init` function of our `NotFound` controller. There we can access and store the custom data that we are passing on when displaying the target manually.

From the router reference we can fetch a reference to the `notFound` target. Each target configuration will create a runtime object that can be accessed through the router.

Similar to SAPUI5 controls, targets define API methods and events that can be attached. We attach a display event handler and save the data that was received as the event parameter `data` in an internal controller variable `_oData`. This data also includes the `fromTarget` information in case the caller passed it on. However, we now have to override the base controller's `onNavBack` implementation to change the behavior a bit. We add a special case for our target back functionality in case the `fromTarget` property has been passed on. If specified, we simply display the target defined as `fromTarget` manually the same way we actually called the `notFound` target manually. Otherwise we just call the base controller's `onNavBack` implementation.

webapp/i18n/i18n.properties

```
...
DisplayNotFound=Display Not Found
```

Add the new property to the `i18n.properties` file.

When we now click the *Back* button, it works as expected and brings us back to the overview page, also when the *Not Found* view is displayed manually.

Conventions

- Display targets manually if you want to trigger a navigation without changing the hash
- Think carefully about all navigation patterns in your application, otherwise the user might get stuck

Step 6: Navigate to Routes with Hard-Coded Patterns

In this step, we'll create a second button on the home page, with which we can navigate to a simple list of employees. This example illustrates how to navigate to a route that has a hard-coded pattern.

Preview

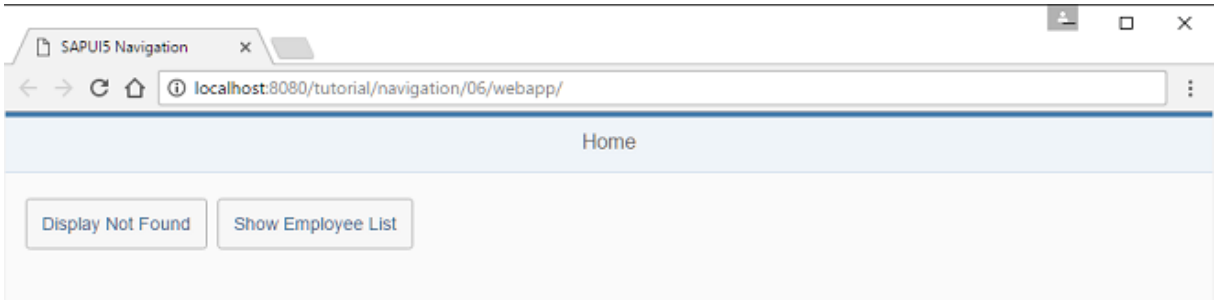

Figure 84: *Show Employee List* button on the *Home* page

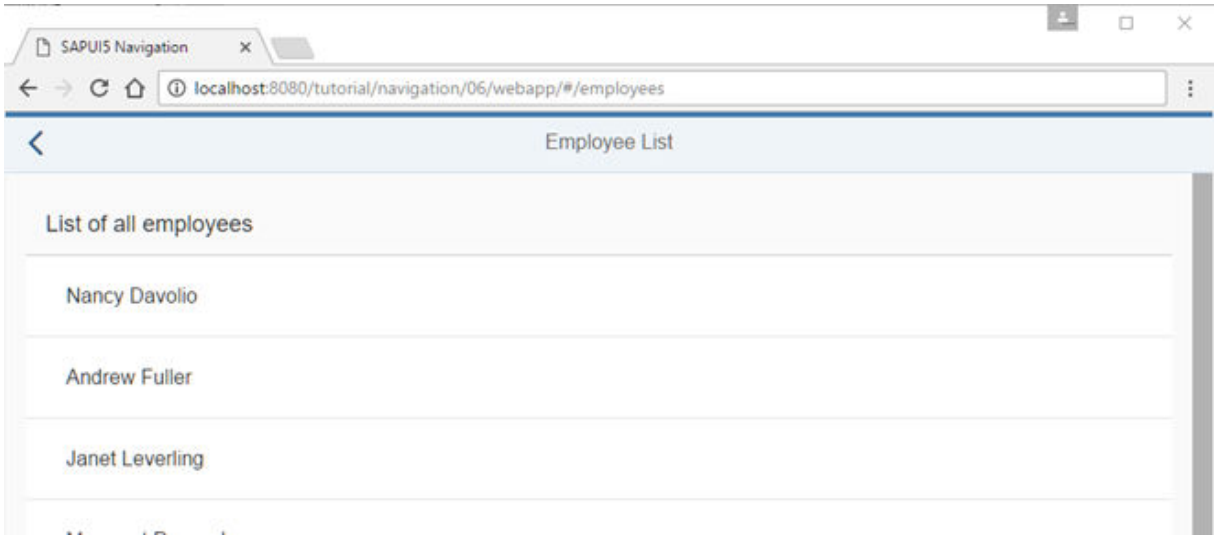

Figure 85: Employee list with *Back* button

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 6.

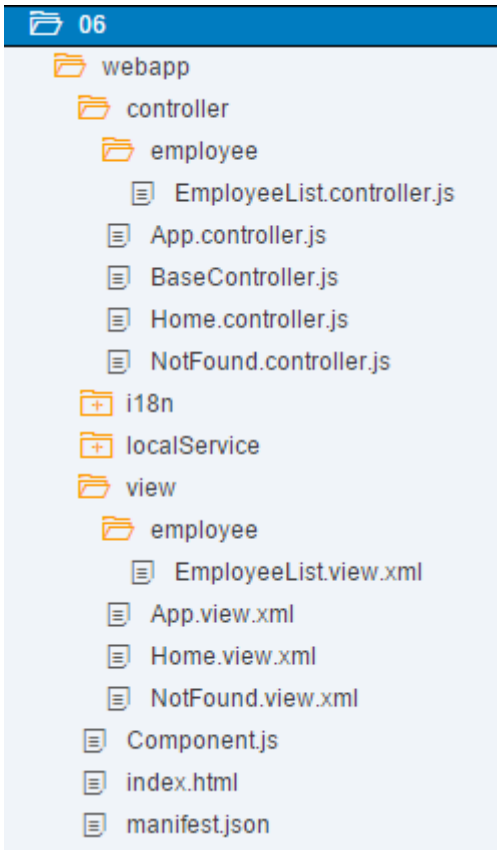

Figure 86: Folder structure for this step

webapp/view/Home.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.Home"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page title="{i18n>homePageTitle}" class="sapUiResponsiveContentPadding">
        <content>
            <Button id="displayNotFoundBtn" text="{i18n>DisplayNotFound}"
press=".onDisplayNotFound" class="sapUiTinyMarginEnd"/>
            <Button id="employeeListBtn" text="{i18n>ShowEmployeeList}"
press=".onNavToEmployees" class="sapUiTinyMarginEnd"/>
        </content>
    </Page>
```

First, we change the `Home` view by adding the *Show Employee List* button. We register an event handler `onNavToEmployees` for the press event.

webapp/controller/Home.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.Home", {
        onDisplayNotFound : function () {
            // display the "notFound" target without changing the hash
            this.getRouter().getTargets().display("notFound", {
                fromTarget : "home"
            });
        },
        onNavToEmployees : function (){
            this.getRouter().navTo("employeeList");
        }
    });
});
```

The new event handler `onNavToEmployees` calls `navTo("employeeList")` on the router instance. The parameter `employeeList` is the name of the route that we want to navigate to.

webapp/manifest.json

```
{
    "_version": "1.12.0",
    "sap.app": {
        ...
    },
    "sap.ui": {
        ...
    },
    "sap.ui5": {
        ...
        "routing": {
            "config": {
```

```
                "routerClass": "sap.m.routing.Router",
                "viewType": "XML",
                "viewPath": "sap.ui.demo.nav.view",
                "controlId": "app",
                "controlAggregation": "pages",
                "transition": "slide",
                "bypassed": {
                    "target": "notFound"
                }
            },
            "routes": [{
                "pattern": "",
                "name": "appHome",
                "target": "home"
            }, {
                "pattern": "employees",
                "name": "employeeList",
                "target": "employees"
            }],
            "targets": {
                "home": {
                    "viewId": "home",
                    "viewName": "Home",
                    "viewLevel" : 1
                },
                "notFound": {
                    "viewId": "notFound",
                    "viewName": "NotFound",
                    "transition": "show"
                },
                "employees": {
                    "viewId": "employeeList",
                    "viewPath": "sap.ui.demo.nav.view.employee",
                    "viewName": "EmployeeList",
                    "viewLevel" : 2
                }
            }
        }
    }
}
```

To make the navigation work, we have to extend the routing configuration of the app in the descriptor file. We add a new pattern called `employeeList`; this is the name we used in the controller to trigger the navigation.

The pattern of the route is the hard-coded value `employees`, meaning the matching hash for this route is `/#/employees` in the address bar of the browser. The target `employees` should be displayed when this URL pattern is matched.

The `employees` entry in the `targets` section references the `sap.ui.demo.nav.view.employee.EmployeeList` view. As you can see, we added a new namespace `employee` for all views related to employees with the property `viewPath`. This overrides the default settings in the `config` section for the current target.

The view that we are about to create has to be placed in the `webapp/view/employee` folder accordingly. This approach helps to structure the views of the app according to business objects and to better understand the navigation patterns of the app in larger projects.

> **i Note**
>
> We could also have left out the `viewPath` property to use the default `viewPath` defined in the `config` section. In that case, we would have to change the `viewName` to `employee.EmployeeList` to achieve the same effect.

Setting the `viewLevel` to `2` helps the router to determine how to animate the (in our case) `slide` transition. For us, this means that a navigation from the home page to the `employees` target will be animated with a "Slide to Left" animation. In contrast to that, the back navigation from the `employees` target to the home page will be animated with a "Slide to Right" animation. This behavior is due to the fact that the home page has a lower `viewLevel` than the `employees` target.

webapp/view/employee/EmployeeList.view.xml (New)

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.employee.EmployeeList"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page
        id="employeeListPage"
        title="{i18n>EmployeeList}"
        showNavButton="true"
        navButtonPress=".onNavBack"
        class="sapUiResponsiveContentPadding">
        <content>
            <List id="employeeList" headerText="{i18n>ListOfAllEmployees}"
items="{/Employees}">
                <items>
                    <StandardListItem
                        title="{FirstName} {LastName}"
                        iconDensityAware="false"
                        iconInset="false"/>
                </items>
            </List>
        </content>
    </Page>
</mvc:View>
```

We now create a subfolder `employee` below `webapp/view` and a file `EmployeeList.view.xml`.

We name the folder after the business object, to make it obvious from looking at the hash (included in the browser's address bar) where a view file for a certain business object is located. For example, we can determine from the URL `/#/employee` that the corresponding view must be somewhere in the folder `./employee` (in our case: `webapp/view/employee`) just by looking at the URL.

In the view, we use a `sap.m.List` control and bind its items to the data from our simulated OData service. Note that we have also registered the `onNavBack` handler from the base controller again to be able to navigate back to the overview.

This view can be referenced by `sap.ui.demo.nav.view.employee.EmployeeList`.

webapp/controller/employee/EmployeeList.controller.js (New)

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return
BaseController.extend("sap.ui.demo.nav.controller.employee.EmployeeList", {
```

```
    });
});
```

Finally, we will add a new controller. Create a subfolder `employee` inside `webapp/controller` folder and place the file `EmployeeList.controller.js` there. As you can see, the folder structure of the controllers is in sync with the folder structure of the views.

webapp/i18n/i18n.properties

```
...
ShowEmployeeList=Show Employee List
EmployeeList=Employee List
ListOfAllEmployees=List of all employees
```

Add the new texts to the `i18n.properties` file.

Now you can open the app and press the *Show Employee List* button to navigate to the employee list. From there, you can press either the browser's or the app's *Back* button to get back to the home page.

Step 7: Navigate to Routes with Mandatory Parameters

In this step, we implement a feature that allows the user to click on an employee in the list to see additional details of the employee. A route pattern can have one or more mandatory parameters to identify objects in an app.

The detail page has to read the ID of the employee from the URL to fetch and display the employee data from the server. If the employee was not found, for example, because an invalid employee ID was passed on, we want to inform the user by displaying the `notFound` target. Of course, the back navigation has to work as well for this page.

                    "viewId": "employee",
                    "viewName": "employee.Employee",
                    "viewLevel" : 3
                }
            }
        }
    }
}
```

From our data model (`webapp/localService/metadata.xml` or `webapp/localService/mockdata/Employees.json`), you can see that each employee entity is identified by an `EmployeeID`. We define a new route that expects a mandatory `employeeId` in its pattern to address an employee. Unlike the patterns we used before, this pattern has a dynamic part. We create a new route `employee` and use `employees/{employeeId}` as its pattern.

The `{employeeId}` part of the pattern is a mandatory parameter as indicated by the curly brackets. The hash that contains an actual employee ID is matched against that pattern at runtime.

The following hashes would match in our case: `employees/2`, `employees/7`, `employees/anInvalidId`, and so on. However, the hash `employees/` will not match as it does not contain an ID at all. The target of our route is `employee`. We create the target `employee` with `viewLevel 3`. With that, we make sure that we have the correct slide animation direction.

Next, we have to create the view `employees.Employee`; for better illustration the `viewPath` is not specified this time.

webapp/view/employee/Employee.view.xml (New)

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.employee.Employee"
    xmlns="sap.m"
```

```
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:f="sap.ui.layout.form"
    busyIndicatorDelay="0">
    <Page
        id="employeePage"
        title="{i18n>EmployeeDetailsOf} {FirstName} {LastName}"
        showNavButton="true"
        navButtonPress=".onNavBack"
        class="sapUiResponsiveContentPadding">
        <content>
            <Panel
                id="employeePanel"
                width="auto"
                class="sapUiResponsiveMargin sapUiNoContentPadding">
                <headerToolbar>
                    <Toolbar>
                        <Title text="{i18n>EmployeeIDColon} {EmployeeID}"
level="H2"/>
                        <ToolbarSpacer />
                    </Toolbar>
                </headerToolbar>
                <content>
                    <f:SimpleForm
                        minWidth="1024"
                        editable="false"
                        layout="ResponsiveGridLayout"
                        labelSpanL="3" labelSpanM="3" emptySpanL="4"
emptySpanM="4"
                        columnsL="1" columnsM="1">
                        <f:content>
                            <Label text="{i18n>formFirstName}"/>
                            <Text text="{FirstName}"/>
                            <Label text="{i18n>formLastName}"/>
                            <Text text="{LastName}"/>
                            <Label text="{i18n>formAddress}"/>
                            <Text text="{Address}"/>
                            <Label text="{i18n>formCity}"/>
                            <Text text="{City}, {Region}"/>
                            <Label text="{i18n>formPostalCode}"/>
                            <Text text="{PostalCode}"/>
                            <Label text="{i18n>formPhoneHome}"/>
                            <Text text="{HomePhone}"/>
                            <Label text="{i18n>formCountry}"/>
                            <Text text="{Country}"/>
                        </f:content>
                    </f:SimpleForm>
                </content>
            </Panel>
        </content>
    </Page>
</mvc:View>
```

Create the file `Employee.view.xml` inside the `webapp/view/employee` folder. This employee view displays master data for an employee in a panel with a `SimpleForm` control: first name, last name and so on. The data comes from a relative data binding that is set on the view level as we can see in the controller later. As we are focusing on the navigation aspects in this tutorial, we won't go into detail on the controls of the view. Just copy the code.

webapp/controller/employee/Employee.controller.js (New)

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
```

```
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.employee.Employee",
{
        onInit: function () {
            var oRouter = this.getRouter();
            oRouter.getRoute("employee").attachMatched(this._onRouteMatched,
this);
            // Hint: we don't want to do it this way
            /*
            oRouter.attachRouteMatched(function (oEvent){
                var sRouteName, oArgs, oView;
                sRouteName = oEvent.getParameter("name");
                if (sRouteName === "employee"){
                    this._onRouteMatched(oEvent);
                }
            }, this);
            */
        },
        _onRouteMatched : function (oEvent) {
            var oArgs, oView;
            oArgs = oEvent.getParameter("arguments");
            oView = this.getView();

            oView.bindElement({
                path : "/Employees(" + oArgs.employeeId + ")",
                events : {
                    change: this._onBindingChange.bind(this),
                    dataRequested: function (oEvent) {
                        oView.setBusy(true);
                    },
                    dataReceived: function (oEvent) {
                        oView.setBusy(false);
                    }
                }
            });
        },
        _onBindingChange : function (oEvent) {
            // No data for the binding
            if (!this.getView().getBindingContext()) {
                this.getRouter().getTargets().display("notFound");
            }
        }
    });
});
```

Now we create the file `Employee.controller.js` in the `webapp/controller/employee` folder. In this controller file, we want to detect which employee shall be displayed in order to show the employee's data in the view. Therefore, we query the router for the route `employee` and attach a private event listener function `_onRouteMatched` to the matched event of this route.

In the event handler, we can access the `arguments` parameter from the `oEvent` parameter that contains all parameters of the pattern. Since this listener is only called when the route is matched, we can be sure that the mandatory parameter `employeeId` is always available as a key in `arguments`; otherwise the route would not have matched. The name of the mandatory parameter `employeeId` correlates to the `{employeeId}` from our pattern definition of the route `employee` and thus to the value in the URL.

In `_onRouteMatched` we call `bindElement()` on the view to make sure that the data of the specified employee is available in the view and it's controls. The `ODataModel` will handle the necessary data requests to the back end in the background. While the data is loading, it would be nice to show a busy indicator by simply setting the view to `busy`. Therefore, we pass an events object to `bindElement()` to listen to the events

`dataRequested` and `dataReceived`. The attached functions handle the busy state by calling `oView.setBusy(true)` and `oView.setBusy(false)` respectively.

We also add an event handler to the `change` event as a private function `_onBindingChange`. It checks if the data could be loaded by querying the binding context of the view. As seen in the previous steps, we will display the `notFound` target if the data could not be loaded.

> **i Note**
>
> Instead of calling `attachMatched(...)` on a route we could also call `attachRouteMatched(...)` directly on the router. However, the event for the latter is fired for every matched event of any route in the whole app. We don't use the latter because we would have to implement an additional check for making sure that current route is the route that has been matched. We want to avoid this extra overhead and register on the route instead.

webapp/view/employee/EmployeeList.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.employee.EmployeeList"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page
        id="employeeListPage"
        title="{i18n>EmployeeList}"
        showNavButton="true"
        navButtonPress=".onNavBack"
        class="sapUiResponsiveContentPadding">
        <content>
            <List id="employeeList" headerText="{i18n>ListOfAllEmployees}"
items="{/Employees}">
                <items>
                    <StandardListItem
                        title="{FirstName} {LastName}"
                        iconDensityAware="false"
                        iconInset="false"
                        type="Navigation"
                        press=".onListItemPressed"/>
                </items>
            </List>
        </content>
    </Page>
</mvc:View>
```

It's time to change the `EmployeeList` view so that we can navigate to the new view. We set the attribute type of the `StandardListItem` template to `Navigation` to make the item clickable and indicate a navigation feature to the user. Additionally, we add an event handler for the `press` event that is called when the user clicks on an employee list item.

webapp/controller/employee/EmployeeList.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
```

```
], function (BaseController) {
    "use strict";
    return
BaseController.extend("sap.ui.demo.nav.controller.employee.EmployeeList", {
        onListItemPressed : function(oEvent){
            var oItem, oCtx;
            oItem = oEvent.getSource();
            oCtx = oItem.getBindingContext();
            this.getRouter().navTo("employee",{
                employeeId : oCtx.getProperty("EmployeeID")
            });
        }
    });
});
```

Finally, we add the handler `onListItemPressed` for the `press` event to the `EmployeeList` controller. In the handler, we determine the `EmployeeID` of the list item by querying the binding context and accessing the property `EmployeeID` from the data model.

Then we navigate to the `employee` route and pass a configuration object on to the `navTo` method with the mandatory parameter `employeeId` filled with the correct `EmployeeID`. The router always makes sure that mandatory parameters as specified in the route's pattern are set; otherwise an error is thrown.

webapp/i18n/i18n.properties

```
...
formEmployeeDetailsOf=Employee Details of
formEmployeeIDColon=Employee ID:
formFirstName=First Name
formLastName=Last Name
formAddress=Address
formCity=City
formPostalCode=Postal Code
formPhoneHome=Phone (Home)
formCountry=Country
```

Add the new texts to the `i18n.properties` file.

That's it. You can go to `webapp/index.html#/employees` and click on any list item to be redirected to corresponding employee's details. Check also what happens when you directly navigate to the following files:

- `webapp/index.html#/employees/3`
- `webapp/index.html#/employees/33`

API Reference: `sap.ui.model.Binding`

Step 8: Navigate with Flip Transition

In this step, we want to illustrate how to navigate to a page with a custom transition animation. Both forward and backward navigation will use the "flip" transition but with a different direction. We will create a simple link on the *Employee* view that triggers a flip navigation to a page that displays the resume data of a certain employee. Pressing the *Back* button will navigate back to the *Employee* view with a reversed flip transition.

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 8.

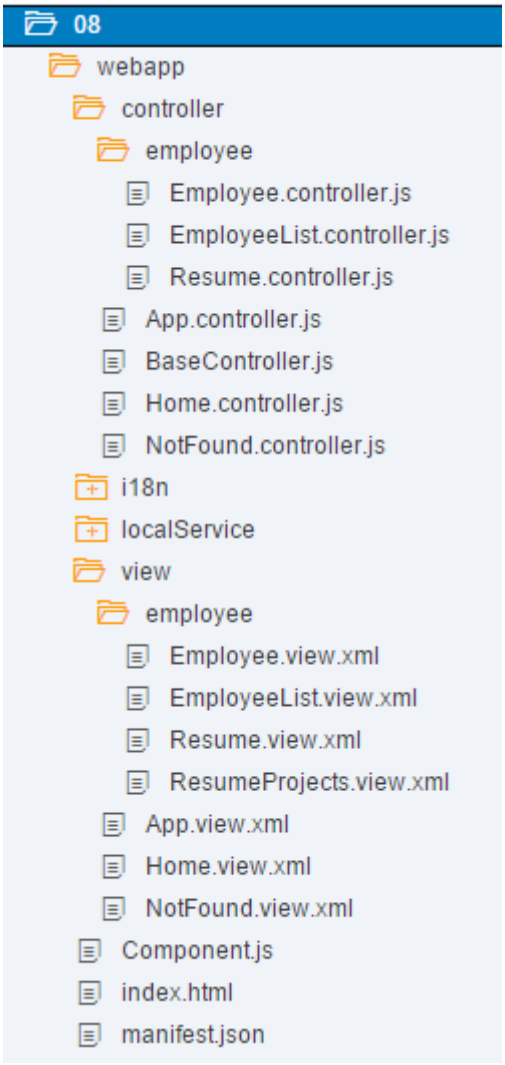

Figure 94: Folder structure for this step

webapp/view/employee/Employee.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.employee.Employee"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:f="sap.ui.layout.form"
    busyIndicatorDelay="0">
    <Page
        id="employeePage"
        title="{i18n>EmployeeDetailsOf} {FirstName} {LastName}"
        showNavButton="true"
        navButtonPress=".onNavBack"
        class="sapUiResponsiveContentPadding">
        <content>
            <Panel
                id="employeePanel"
                width="auto"
                class="sapUiResponsiveMargin sapUiNoContentPadding">
                <headerToolbar>
                    <Toolbar>
```

```
                        <Title text="{i18n>EmployeeIDColon} {EmployeeID}"
level="H2"/>
                        <ToolbarSpacer />
                        <Link text="{i18n>FlipToResume}"
tooltip="{i18n>FlipToResume.tooltip}" press=".onShowResume"/>
                    </Toolbar>
                </headerToolbar>
                <content>
                    ...
                </content>
            </Panel>
        </content>
    </Page>
</mvc:View>
```

First we add the *Flip to Resume* link to the *Employee Details* view to trigger the navigation to the resume of the employee that is currently displayed.

webapp/controller/employee/Employee.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.employee.Employee",
{
        ...
        _onBindingChange : function (oEvent) {
            // No data for the binding
            if (!this.getView().getBindingContext()) {
                this.getRouter().getTargets().display("notFound");
            }
        }
            ...
        },
        onShowResume : function (oEvent) {
            var oCtx = this.getView().getElementBinding().getBoundContext();

            this.getRouter().navTo("employeeResume", {
                employeeId : oCtx.getProperty("EmployeeID")
            });
        }
    });
});
```

Then we change the `Employee.controller.js` file by adding the press handler `onShowResume` for the *Flip to Resume* link. The handler simply navigates to a new route `employeeResume` and fills the mandatory parameter `employeeId` with the property `EmployeeID` from the view's bound context. The route `employeeResume` is not available yet, so we will have to add it to our routing configuration.

                },
                "employees": {
                    "viewId": "employees",
                    "viewPath": "sap.ui.demo.nav.view.employee",
                    "viewName": "EmployeeList",
                    "viewLevel" : 2
                },
                "employee": {
                    "viewId": "employee",
                    "viewName": "employee.Employee",
                    "viewLevel" : 3
                },
                "employeeResume": {
                    "viewId": "resume",
                    "viewName": "employee.Resume",
                    "viewLevel" : 4,
                    "transition": "flip"
                }
            }
        }
    }
}
```

In the routing configuration, we add a new route `employeeResume` which references a target with the same name. The route's pattern expects an `{employeeId}` as a mandatory parameter and ends with the static string `/resume`.

The target `employeeResume` references the view `employee.Resume` that we are about to create. The target's `viewLevel` is `4`; compared to the employee target this is one level lower again. To configure a flip navigation, we simply set the transition of our target to `flip`. Together with the correct `viewLevel` configuration this will trigger the correct forward and backward flip navigation whenever the target is displayed.

> **i Note**
>
> Possible values for the `transition` parameter are:
>
> - `slide` (default)
> - `flip`
> - `show`
> - `fade`
>
> You can also implement your own transitions and add it to a control that extends `sap.m.NavContainer` (for example, `sap.m.App` or `sap.m.SplitApp`). For more information, see the *API Reference* for `NavContainer`.

webapp/view/employee/Resume.view.xml (New)

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.employee.Resume"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page
        title="{i18n>ResumeOf} {FirstName} {LastName}"
        id="employeeResumePage"
        showNavButton="true"
        navButtonPress=".onNavBack">
        <content>
            <IconTabBar
                id="iconTabBar"
                headerBackgroundDesign="Transparent"
                class="sapUiResponsiveContentPadding"
                binding="{Resume}">
                <items>
                    <IconTabFilter id="infoTab" text="{i18n>tabInfo}" key="Info">
                        <Text text="{Information}"/>
                    </IconTabFilter>
                    <IconTabFilter id="projectsTab" text="{i18n>tabProjects}"
key="Projects">
                        <mvc:XMLView
viewName="sap.ui.demo.nav.view.employee.ResumeProjects"></mvc:XMLView>
                    </IconTabFilter>
                    <IconTabFilter id="hobbiesTab" text="{i18n>tabHobbies}"
key="Hobbies">
                        <Text text="{Hobbies}"/>
                    </IconTabFilter>
                    <IconTabFilter id="notesTab" text="{i18n>tabNotes}"
key="Notes">
                        <Text text="{Notes}"/>
                    </IconTabFilter>
                </items>
```

```
            </IconTabBar>
        </content>
    </Page>
</mvc:View>
```

Create a file `Resume.view.xml` inside the `webapp/view/employee` folder. The view uses an `IconTabBar` to display the resume data. Therefore, its binding attribute is set to `{Resume}`.

In the `IconTabBar` we display four tabs. Three of them simply use a `Text` control to display the data from the service. The *Projects* tab uses a nested XML view to display the projects of the employee. SAPUI5 takes care of loading the XML view automatically when the user navigates to the *Resume* page.

webapp/controller/employee/Resume.controller.js (New)

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.employee.Resume", {
        onInit: function () {
            var oRouter = this.getRouter();

oRouter.getRoute("employeeResume").attachMatched(this._onRouteMatched, this);
        },
        _onRouteMatched : function (oEvent) {
            var oArgs, oView;
            oArgs = oEvent.getParameter("arguments");
            oView = this.getView();
            oView.bindElement({
                path : "/Employees(" + oArgs.employeeId + ")",
                events : {
                    change: this._onBindingChange.bind(this),
                    dataRequested: function (oEvent) {
                        oView.setBusy(true);
                    },
                    dataReceived: function (oEvent) {
                        oView.setBusy(false);
                    }
                }
            });
        },
        _onBindingChange : function (oEvent) {
            // No data for the binding
            if (!this.getView().getBindingContext()) {
                this.getRouter().getTargets().display("notFound");
            }
        }
    });
});
```

Create a file `Resumee.controller.js` in the `webapp/controller/employee` folder. In this controller, we make sure to bind the view to the correct employee whenever the `employeeResume` route has matched. We have already used this approach in the previous step so you should be able to recognize the building blocks in the code above. Again, in case the user cannot be found we display the `notFound` target.

webapp/view/employee/ResumeProjects.view.xml (New)

```
<mvc:View xmlns="sap.m" xmlns:mvc="sap.ui.core.mvc">
    <Text text="{Projects}"/>
</mvc:View>
```

Create a file `ResumeProjects.view.xml` in the `webapp/view/employee` folder. This view does not have a controller as we don't need it. It just displays a `Text` control with the projects text of the selected employee. It illustrates that using nested views works just fine in combination with navigation and routing in SAPUI5.

> **i** Note
>
> For more complex applications, the performance is significantly increased if parts of the UI are only loaded when the user is actively selecting it. In this example, the view is always loaded even though the user never decided to display the project information. In the next steps, we will extend the UI so that the content is loaded "lazy" by SAPUI5 only when the filter item is clicked. The back-end service will fetch the data only on request and the UI will only have to be updated with the selected data instead of loading all data.

webapp/i18n/i18n.properties

```
...
ResumeOf=Resume of
tabInfo=Info
tabProjects=Projects
tabHobbies=Hobbies
tabNotes=Notes
FlipToResume=Flip to Resume
FlipToResume.tooltip=See the resume of this employee
```

Add the new texts to the `i18n.properties` file.

You can go to `webapp/index.html#/employees/3` and click on the *Flip to Resume* link to be redirected with a nice flip transition to the employee's resume. The back navigation uses a reverse flip navigation to get back to the *Employee Details* page. You can also directly navigate to `webapp/index.html#/employees/3/resume` or `webapp/index.html#/employees/33/resume` to see what happens.

API Overview and Samples: `sap.m.NavContainer`

Step 9: Allow Bookmarkable Tabs with Optional Query Parameters

The `resume` view contains four tabs as we have seen in the previous steps. However, when the user navigates to the `resume` page, only the first tab is displayed initially. Navigating directly to a specific tab or bookmarking a tab is not yet supported in our current app.

In this step, we implement a bookmarking feature by enabling deep linking to tabs with optional query parameters. A deep link is basically a link that directly references a deeper structure and parameters of the app in the URL. It is often bookmarked or shared to have a convenient entry point into the app for a certain task or action. The selected tab should be reflected in the URL but the tab can also be omitted, for example, when we initially navigate to the resume page.

Preview

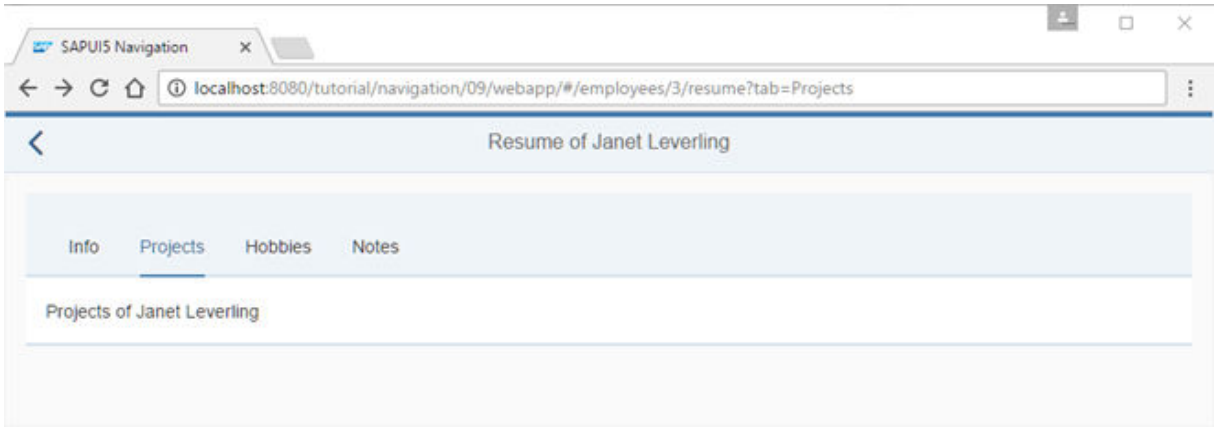

Figure 95: Deep link to allow bookmarkable tabs

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 9.

webapp/manifest.json

```
{
    "_version": "1.12.0",
    "sap.app": {
        ...
    },
    "sap.ui": {
        ...
    },
    "sap.ui5": {
        ...
        "routing": {
```

```
            "config": {
                "routerClass": "sap.m.routing.Router",
                "viewType": "XML",
                "viewPath": "sap.ui.demo.nav.view",
                "controlId": "app",
                "controlAggregation": "pages",
                "transition": "slide",
                "bypassed": {
                    "target": "notFound"
                }
            },
            "routes": [{
                "pattern": "",
                "name": "appHome",
                "target": "home"
            }, {
                "pattern": "employees",
                "name": "employeeList",
                "target": "employees"
            }, {
                "pattern": "employees/{employeeId}",
                "name": "employee",
                "target": "employee"
            }, {
                "pattern": "employees/{employeeId}/resume:?query:",
                "name": "employeeResume",
                "target": "employeeResume"
            }],
            "targets": {
                ...
            }
        }
    }
}
```

Up until now, you could only navigate to an employee's resume with the deep link `webapp/index.html#/employees/3/resume`. This will always select the first tab as implemented by the `IconTabBar` control. In order to open the page directly with a specific tab selected and to make the tabs bookmarkable, we add the `?query` parameter to the URL pattern.

This allows URLs like `webapp/index.html#/employees/3/resume?tab=Projects` where the query parameter defines which tab shall be displayed. We change the pattern of the `employeeResume` route to `employees/{employeeId}/resume:?query:`. The new part `:?query:` allows to pass on queries with any parameters, for example, the hash `/#/employees/3/resume?tab=Projects` or `/#/employees/3/resume?tab=Projects&action=edit` matches the pattern and can be processed in the matched event.

The `:?query:` parameter starts and ends with ":", which means that it is optional. If you want to make it mandatory, you can use the `{?query}` syntax (everything in between `{}` is considered as being mandatory).

webapp/view/employee/Resume.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.employee.Resume"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page
        title="{i18n>ResumeOf} {FirstName} {LastName}"
        id="employeeResumePage"
        showNavButton="true"
```

```
        navButtonPress=".onNavBack">
        <content>
            <IconTabBar
                id="iconTabBar"
                headerBackgroundDesign="Transparent"
                class="sapUiResponsiveContentPadding"
                binding="{Resume}"
                select=".onTabSelect"
                selectedKey="{view>/selectedTabKey}">
                <items>
                    <IconTabFilter id="infoTab" text="{i18n>tabInfo}" key="Info">
                        <Text text="{Information}"/>
                    </IconTabFilter>
                    <IconTabFilter id="projectsTab" text="{i18n>tabProjects}"
key="Projects">
                        <mvc:XMLView
viewName="sap.ui.demo.nav.view.employee.ResumeProjects"></mvc:XMLView>

                    <IconTabFilter id="hobbiesTab" text="{i18n>tabHobbies}"
key="Hobbies">
                        <Text text="{Hobbies}"/>
                    </IconTabFilter>
                    <IconTabFilter id="notesTab" text="{i18n>tabNotes}"
key="Notes">
                        <Text text="{Notes}"/>
                    </IconTabFilter>
                </items>
            </IconTabBar>
        </content>
    </Page>
</mvc:View>
```

To update the currently selected tab in the URL we listen to the select event of the `IconTabBar` by setting `select=".onTabSelect"` in the resume view. The `selectedKey` is bound to a view model. This allows to easily change the `selectedKey` according to the selected tab in the URL.

webapp/controller/employee/Resume.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController",
    "sap/ui/model/json/JSONModel"
], function (BaseController, JSONModel) {
    "use strict";
    var _aValidTabKeys = ["Info", "Projects", "Hobbies", "Notes"];
    return BaseController.extend("sap.ui.demo.nav.controller.employee.Resume", {
        onInit: function () {
            var oRouter = this.getRouter();
            this.getView().setModel(new JSONModel(), "view");

oRouter.getRoute("employeeResume").attachMatched(this._onRouteMatched, this);
        },
        _onRouteMatched: function (oEvent) {
            var oArgs, oView, oQuery;
            oArgs = oEvent.getParameter("arguments");
            oView = this.getView();
            oView.bindElement({
                path: "/Employees(" + oArgs.employeeId + ")",
                events: {
                    change: this._onBindingChange.bind(this),
                    dataRequested: function (oEvent) {
                        oView.setBusy(true);
                    },
```

```
                    dataReceived: function (oEvent) {
                        oView.setBusy(false);
                    }
                }
            });
            oQuery = oArgs["?query"];
            if (oQuery && _aValidTabKeys.indexOf(oQuery.tab) > -1){
                oView.getModel("view").setProperty("/selectedTabKey",
oQuery.tab);
            } else {
                // the default query param should be visible at all time
                this.getRouter().navTo("employeeResume", {
                    employeeId: oArgs.employeeId,
                    "?query": {
                        tab: _aValidTabKeys[0]
                    }
                }, true /*no history*/);
            }
        },
        _onBindingChange: function (oEvent) {
            // No data for the binding
            if (!this.getView().getBindingContext()) {
                this.getRouter().getTargets().display("notFound");
            }
        },
        onTabSelect: function (oEvent){
            var oCtx = this.getView().getBindingContext();
            this.getRouter().navTo("employeeResume", {
                employeeId: oCtx.getProperty("EmployeeID"),
                "?query": {
                    tab: oEvent.getParameter("selectedKey")
                }
            }, true /*without history*/);
        }
    });
});
```

When a tab is selected manually, its select handler is called. Therefore, let's first have a look at the `onTabSelect` event handler that is added at the end of the `resume` controller. It detects the `selectedKey` of the tab and navigates to the `employeeResume` route to update the URL in the address bar. Additionally to the mandatory parameter `employeeId`, we pass on a custom `query` object with a parameter `tab` and fill it with the `selectedKey` value that we receive from the `select` event of the `IconTabBar`. By passing on `true` as the third argument we replace the current history to make sure that manually clicked tabs won't be added to the browser history.

A dependency to `sap/ui/model/json/JSONModel` is added to the controller. Now, we modify the `onInit` function to instantiate a JSONModel and use it as the `view` model. `_aValidTabKeys` is added to the controller. We want to make sure that only valid tabs can be selected. Therefore, the `array _aValidTabKeys` contains all allowed tab keys that we can check against to validate the tab parameter from the URL later. The keys are equal to the keys of our `IconTabFilters` in the `resume` view.

In the `_onRouteMatched` event handler, we add the `oQuery` variable to store a reference to the query object from the router. This allows a more comfortable access to the query object.

In case a query object is passed on and the `tab` parameter has a valid value, we display the specific tab by updating the property `selectedTabKey` in the view model. As the `selectedKey` property of the `IconTabBar` is bound to `{view>/selectedTabKey}` the corresponding tab is selected.

The `else` case is called when either no or an invalid tab parameter is specified. We navigate to the *Info* tab to make sure that the tab parameter is reflected in the URL at all times. The actual requirements of your app might differ, feel free to change it accordingly...

From now on our tabs are bookmarkable. Try to access the following (deep) links directly:

- `webapp/index.html#/employees/3/resume`
- `webapp/index.html#/employees/3/resume?tab=Info`
- `webapp/index.html#/employees/3/resume?tab=Projects`
- `webapp/index.html#/employees/3/resume?tab=Hobbies`
- `webapp/index.html#/employees/3/resume?tab=Notes`
- `webapp/index.html#/employees/3/resume?tab=SomethingInvalid`

When you click on any tab you will see that the hash in the URL changes immediately, and when you change the hash in the URL parameter manually, you can see that the UI is also updated accordingly.

Step 10: Implement “Lazy Loading”

In the previous steps, we have implemented a *Resume* view that uses tabs to display data. The complete content of the tabs is loaded once, no matter which tab is currently displayed. We can increase the performance of our app by avoiding to load content that is not visible. Therefore, we implement a “lazy loading” feature that only loads the view and data when requested by the user.

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 10 .

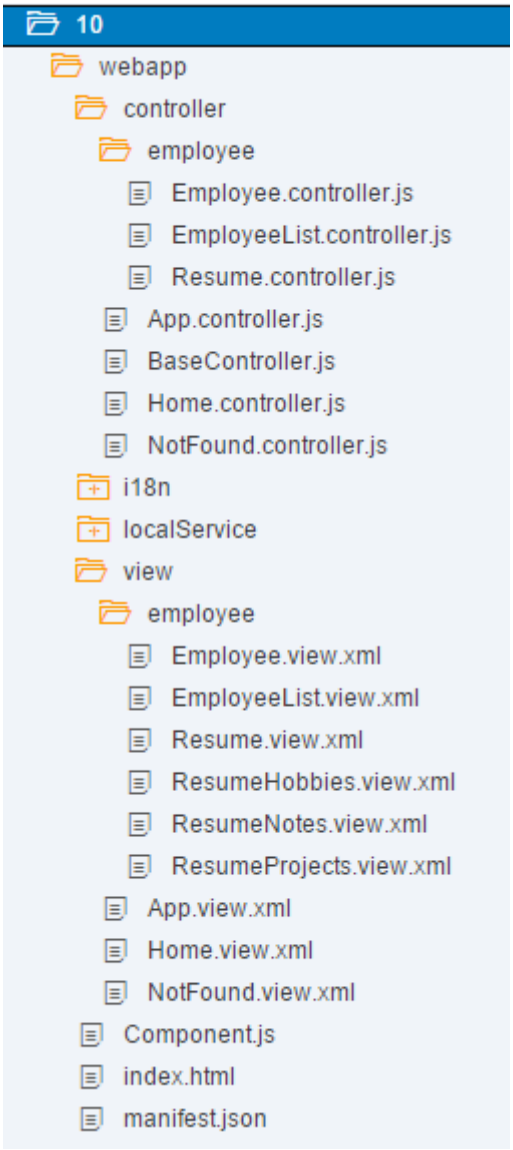

Figure 97: Folder Structure for this Step

webapp/view/employee/Resume.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.employee.Resume"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page
        title="{i18n>ResumeOf} {FirstName} {LastName}"
        id="employeeResumePage"
        showNavButton="true"
        navButtonPress=".onNavBack">
        <content>
            <IconTabBar
                id="iconTabBar"
                headerBackgroundDesign="Transparent"
                class="sapUiResponsiveContentPadding"
                binding="{Resume}"
                select=".onTabSelect"
```

```
                selectedKey="{view>/selectedTabKey}">
                <items>
                    <IconTabFilter id="infoTab" text="{i18n>tabInfo}" key="Info">
                        <Text text="{Information}"/>
                    </IconTabFilter>
                    <IconTabFilter id="projectsTab" text="{i18n>Projects}"
key="Projects">
                        <mvc:XMLView
viewName="sap.ui.demo.nav.view.employee.ResumeProjects"></mvc:XMLView>
                    </IconTabFilter>
                    <IconTabFilter id="hobbiesTab" text="{i18n>Hobbies}"
key="Hobbies">
                        <!-- place content via lazy loading -->
                    </IconTabFilter>
                    <IconTabFilter id="notesTab" text="{i18n>Notes}" key="Notes">
                        <!-- place content via lazy loading -->
                    </IconTabFilter>
                </items>
            </IconTabBar>
        </content>
    </Page>
</mvc:View>
```

To illustrate lazy loading, we implement that the content is loaded only when the user selects the corresponding tab for two of our tabs from the `IconTabBar`: *Hobbies* and *Notes*. The `IconTabFilter` controls each have a hard-coded ID so that we can address them later in our routing configuration. In real use cases, you would do this for tabs that contain a lot of content or trigger expensive service calls to a back-end service.

In the `resume` view we remove the content of the *Hobbies* and *Notes* tabs as we will now fill it dynamically with navigation features.

webapp/view/employee/ResumeHobbies.view.xml (New)

```
<mvc:View xmlns="sap.m" xmlns:mvc="sap.ui.core.mvc">
    <Text text="{Hobbies}"/>
</mvc:View>
```

Create the file `ResumeHobbies.view.xml` in the `webapp/view/employee` folder. Move the content for the tab that was previously in the `resume` view to that view. We don't need a controller for this view as there is no additional logic involved. This view will be lazy-loaded and placed into the content of the *Hobbies* tab with navigation features.

webapp/view/employee/ResumeNotes.view.xml (New)

```
<mvc:View xmlns="sap.m" xmlns:mvc="sap.ui.core.mvc">
    <Text text="{Notes}"/>
</mvc:View>
```

Create the file `ResumeNotes.view.xml` in the `webapp/view/employee` folder similar to the *Hobbies* view to transform this tab to a separate view as well.

webapp/controller/employee/Resume.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController",
    "sap/ui/model/json/JSONModel"
], function (BaseController, JSONModel) {
    "use strict";
    var _aValidTabKeys = ["Info", "Projects", "Hobbies", "Notes"];
    return BaseController.extend("sap.ui.demo.nav.controller.employee.Resume", {
        ...
        _onRouteMatched : function (oEvent) {
            var oArgs, oView, oQuery;
            oArgs = oEvent.getParameter("arguments");
            oView = this.getView();
            oView.bindElement({
                ...
            });
            oQuery = oArgs["?query"];
            if (oQuery && _aValidTabKeys.indexOf(oQuery.tab) > -1){
                oView.getModel("view").setProperty("/selectedTabKey",
oQuery.tab);
                // support lazy loading for the hobbies and notes tab
                if (oQuery.tab === "Hobbies" || oQuery.tab === "Notes"){
                    // the target is either "resumeTabHobbies" or
"resumeTabNotes"
                    this.getRouter().getTargets().display("resumeTab" +
oQuery.tab);
                }
            } else {
                // the default query param should be visible at all time
                this.getRouter().navTo("employeeResume", {
                    employeeId : oArgs.employeeId,
                    "?query": {
                        tab : _aValidTabKeys[0]
                    }
                }, true /*no history*/);
            }
        },
        ...
    });
});
```

Now we extend the `resume` controller a little and add additional logic to the part of the `_onRouteMatched` function where a new tab has been selected and validated. In case the `selectedKey` matches `Hobbies` or `Notes` we call `this.getRouter().getTargets().display("resumeTab" + oQuery.tab)` to display the corresponding target manually. Here the valid targets are `resumeTabHobbies` and `resumeTabNotes` as we have changed the behavior for these two tabs by creating separate views.

These lines of code make sure that the targets are only loaded when they are needed (“lazy loading”). But the router does not know the new targets yet, so let’s create them in our routing configuration.

webapp/manifest.json

```
{
    "_version": "1.12.0",
    "sap.app": {
        ...
    },
```

```
    "sap.ui": {
        ...
    },
    "sap.ui5": {
        ...
        "routing": {
            "config": {
                "routerClass": "sap.m.routing.Router",
                "viewType": "XML",
                "viewPath": "sap.ui.demo.nav.view",
                "controlId": "app",
                "controlAggregation": "pages",
                "transition": "slide",
                "bypassed": {
                    "target": "notFound"
                }
            },
            "routes": [{
                ...
            }, {
                "pattern": "employees/{employeeId}/resume:?query:",
                "name": "employeeResume",
                "target": "employeeResume"
            }],
            "targets": {
                ...
                "employeeResume": {
                    "viewId": "resume",
                    "viewName": "employee.Resume",
                    "viewLevel" : 4,
                    "transition": "flip"
                },
                "resumeTabHobbies": {
                    "viewId": "resumeHobbies",
                    "parent": "employeeResume",
                    "viewPath": "sap.ui.demo.nav.view.employee",
                    "viewName": "ResumeHobbies",
                    "controlId": "hobbiesTab",
                    "controlAggregation": "content"
                },
                "resumeTabNotes": {
                    "viewId": "resumeNotes",
                    "parent": "employeeResume",
                    "viewPath": "sap.ui.demo.nav.view.employee",
                    "viewName": "ResumeNotes",
                    "controlId": "notesTab",
                    "controlAggregation": "content"
                }
            }
        }
    }
}
```

We add the `resumeTabHobbies` and `resumeTabNotes` targets to the descriptor file with additional fields that override the default configuration as we now want to display the targets locally inside the `IconTabBar` control and not as pages of the app.

The `resumeTabHobbies` target sets the parent property to `employeeResume`. The parent property expects the name of another target. In our case, this makes sure that the view from the parent target `employeeResume` is loaded before the target `resumeTabHobbies` is displayed. This can be considered as a “view dependency”. By setting the `controlId` and `controlAggregation` properties the router places the view `ResumeHobbies` into the `content` aggregation of the `IconTabFilter` control with ID `hobbiesTab`. We also set a parameter `viewId` to a custom ID to illustrate how you could overrule a hard-coded ID inside a view.

> **i Note**
>
> Each target can define only one parent with its parent property. This is similar to the SAPUI5 control tree where each control can have only one parent control (accessed with the method `getParent()` of `sap.ui.base.ManagedObject`). The `controlId` property always references a control inside the parent view that is specified with the `parent` target.

Now we add the `resumeTabNotes` target similar to the `Hobbies` target. The `resumeTabNotes` target defines the parent target `employeeResume` as well, because they share the same parent view. We place the `ResumeNotes` view into the `content` aggregation of the `IconTabFilter` control with ID `notesTab`.

We have now implemented lazy loading for the tabs *Hobbies* and *Notes*. These two tabs are now managed by the routing configuration and only loaded when we click on them the first time.

Try it out yourself: Open the *Network* tab of your browser's developer tools and click on the tabs of your app. In the network traffic you will see that `ResumeHobbies.view.xml` file is only loaded when the *Hobbies* tab is displayed the first time. The same applies for the *Notes* tab. Mission accomplished!

Conventions

- Lazy-load content that is not initially displayed to the user

API Reference: `ap.m.routing.Targets`

Step 11: Assign Multiple Targets

In this step, we will add a new button to the home page to illustrate the usage of multiple targets for a route. When the button is pressed, a new page opens that contains two parts: a header part at the top and a content part. The content part displays a table of employees that can be sorted and searched. We will use the array notation in the routing configuration to assign multiple targets to a route - a feature that we have not yet introduced.

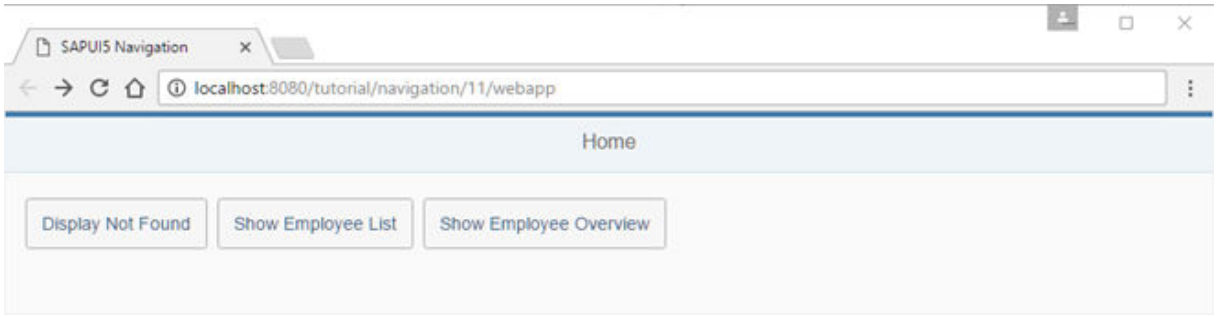

Figure 98: New button *Show Employee Overview*

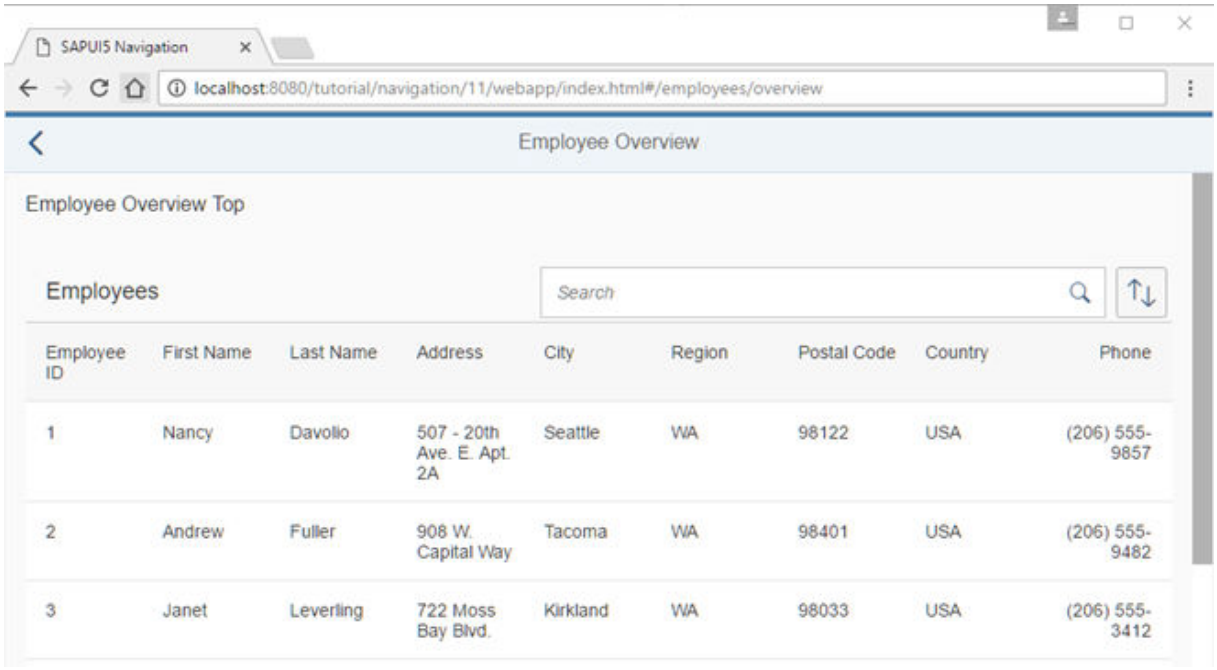

Figure 99: *Employee Overview* with search field

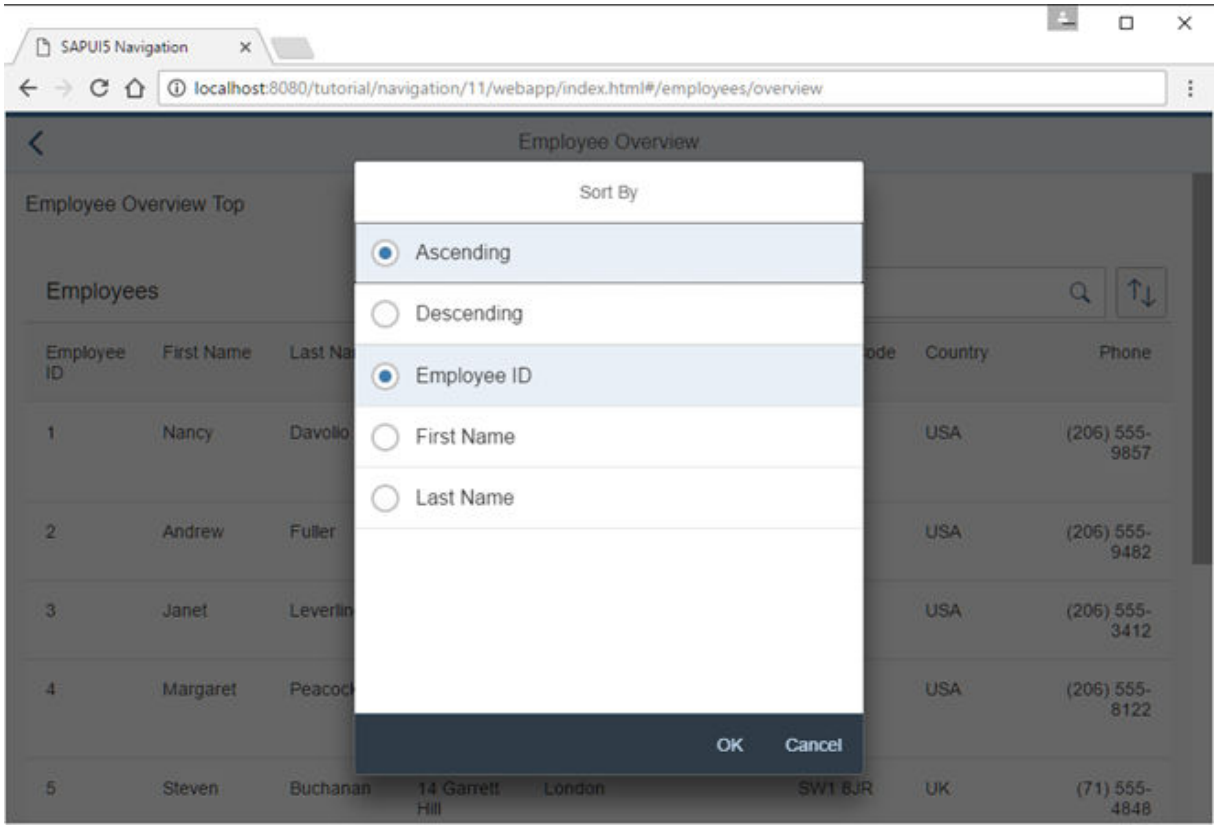

Figure 100: Sort options for the *Employee Overview*

Coding

You can view and download all files in the Demo Kit at Routing and Navigation - Step 11 .

Figure 101: Folder Structure for this Step

webapp/view/Home.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.nav.controller.Home"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page title="{i18n>homePageTitle}" class="sapUiResponsiveContentPadding">
        <content>
            <Button id="displayNotFoundBtn" text="{i18n>DisplayNotFound}"
press=".onDisplayNotFound" class="sapUiTinyMarginEnd"/>
            <Button id="employeeListBtn" text="{i18n>ShowEmployeeList}"
press=".onNavToEmployees" class="sapUiTinyMarginEnd"/>
            <Button id="employeeOverviewBtn" text="{i18n>ShowEmployeeOverview}"
press=".onNavToEmployeeOverview" class="sapUiTinyMarginEnd"/>
        </content>
    </Page>
</mvc:View>
```

First we add a new button to the `Home` view and add an event handler for the `press` event.

webapp/controller/Home.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.Home", {
        ...
        onNavToEmployees : function () {
            this.getRouter().navTo("employeeList");
        },
        onNavToEmployeeOverview : function ()  {
            this.getRouter().navTo("employeeOverview");
        }
    });
});
```

As you know already from the previous steps, we add the `press` event handler `onNavToEmployeeOverview`. It navigates to the route `employeeOverview` which does not exist yet, so let's create it.

webapp/manifest.json

```
{
    "_version": "1.12.0",

                "name": "employeeOverview",
                "target": ["employeeOverviewTop", "employeeOverviewContent"]
            }, {
                "pattern": "employees/{employeeId}",
                "name": "employee",
                "target": "employee"
```

```
            }, {
                "pattern": "employees/{employeeId}/resume:?query:",
                "name": "employeeResume",
                "target": "employeeResume"
            }],
            "targets": {
                ...
                "resumeTabNotes": {
                    "viewId": "resumeNotes",
                    "parent": "employeeResume",
                    "viewPath": "sap.ui.demo.nav.view.employee",
                    "viewName": "ResumeNotes",
                    "controlId": "notesTab",
                    "controlAggregation": "content"
                },
                "employeeOverview": {
                    "viewId": "employeeOverview",
                    "viewPath": "sap.ui.demo.nav.view.employee.overview",
                    "viewName": "EmployeeOverview",
                    "viewLevel" : 2
                },
                "employeeOverviewTop": {
                    "viewId": "employeeOverviewTop",
                    "parent": "employeeOverview",
                    "viewPath": "sap.ui.demo.nav.view.employee.overview",
                    "viewName": "EmployeeOverviewTop",
                    "controlId": "EmployeeOverviewParent",
                    "controlAggregation": "content"
                },
                "employeeOverviewContent": {
                    "viewId": "employeeOverviewContent",
                    "parent": "employeeOverview",
                    "viewPath": "sap.ui.demo.nav.view.employee.overview",
                    "viewName": "EmployeeOverviewContent",
                    "controlId": "EmployeeOverviewParent",
                    "controlAggregation": "content"
                }
            }
        }
    }
}
```

We extend our current routing configuration with a new route `employeeOverview`. Note that this route has to be configured before the `employee` route, else the `employee` route would be matched with a hash like `/#/employees/overview`. The new route `employeeOverview` references two targets at the same time with an array notation: `employeeOverviewTop` and `employeeOverviewContent`. As you can see here, a route can reference an arbitrary number of targets that will be displayed when the route is matched.

Both targets `employeeOverviewTop` and `employeeOverviewContent` reference the target `employeeOverview` as their parent target because we want to place them both inside the parent. Please also note that we also introduce a new layer `overview` in the `viewPath` property.

i Note

The order of the routing configuration matters here, because the router stops matching additional routes when the first match is found. You can override this behavior if you set parameter `greedy` to `true` on the route. Then the route will always be matched when the pattern matches the current URL, even if another route has been matched before. The `greedy` option comes from the underlying `Crossroads.js` library, a popular routing library. A common use case for using `greedy` is configuring targets without views and then listening for route-matched events.

Now we create both targets `employeeOverviewTop` and `employeeOverviewContent` as well as their parent target `employeeOverview`. On the parent target we set `viewLevel` to `2` to ensure a correct transition animation. In the targets, we also configure where the corresponding views of the children shall be displayed by setting the parameters `controlId` and `controlAggregation` to a control ID of a `sap.ui.layout.HorizontalLayout` that we are about to create in a new view. You should be familiar with this configuration from the last step.

The router makes sure that the parent view is loaded in addition to the target view when a corresponding route has been matched and the targets are displayed. The referenced views are displayed automatically at the configured place in the parent's view, in our case in the content aggregation of the page control. We have mentioned three different views that we still need to add to the app to make the configuration work:

- `EmployeeOverview`
- `EmployeeOverviewTop`
- `EmployeeOverviewContent`

webapp/view/employee/overview/EmployeeOverview.view.xml (New)

```
<mvc:View

controllerName="sap.ui.demo.nav.controller.employee.overview.EmployeeOverview"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page id="EmployeeOverviewParent" title="{i18n>EmployeeOverview}"
        showNavButton="true"
        navButtonPress=".onNavBack"
        class="sapUiResponsiveContentPadding">
        <content>
            <!-- inserted by routing -->
        </content>
    </Page>
</mvc:View>
```

First we create the parent view by creating the folder `overview` under `webapp/view/employee` and placing the file `EmployeeOverview.view.xml` into that folder. This view contains a `Page` control that is referenced from the targets in our `manifest.json` descriptor file. The content aggregation of the page will be filled by the router with the top and content part when the corresponding route has been hit.

webapp/controller/employee/overview/EmployeeOverview.controller.js (New)

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return
BaseController.extend("sap.ui.demo.nav.controller.employee.overview.EmployeeOverv
iew", {
    });
});
```

The controller does not contain any logic yet, but we will add back navigation features here in the next steps.

webapp/view/employee/overview/EmployeeOverviewTop.view.xml (New)

```
<mvc:View xmlns="sap.m" xmlns:mvc="sap.ui.core.mvc"
class="sapUiMediumMarginBottom">
    <Title text="{i18n>EmployeeOverviewTop}"/>
</mvc:View>
```

Create the file `EmployeeOverviewTop.view.xml` and place it in the `webapp/view/employee/overview` folder. This view displays a static text for illustration purposes. Change it according to your own requirements. We don't need a controller for this view

webapp/view/employee/overview/EmployeeOverviewContent.view.xml (New)

```
<mvc:View

controllerName="sap.ui.demo.nav.controller.employee.overview.EmployeeOverviewCont
ent"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Table id="employeesTable"
        items="{/Employees}">
        <headerToolbar>
            <Toolbar>
                <Title text="{i18n>Employees}" level="H2"/>
                <ToolbarSpacer />
                <SearchField id="searchField" search=".onSearchEmployeesTable"
width="50%"/>
                <Button icon="sap-icon://sort" press=".onSortButtonPressed"/>
            </Toolbar>
        </headerToolbar>
        <columns>
            <Column id="employeeIDCol"><Text text="{i18n>EmployeeID}"/></Column>
            <Column id="firstNameCol" demandPopin="true"><Text
text="{i18n>FirstName}"/></Column>
            <Column id="lastNameCol" demandPopin="true"><Text
text="{i18n>LastName}"/></Column>
            <Column id="addressCol" minScreenWidth="Tablet"
demandPopin="true"><Text text="{i18n>Address}"/></Column>
            <Column id="cityCol" minScreenWidth="Tablet"
demandPopin="true"><Text text="{i18n>City}"/></Column>
            <Column id="regionCol" minScreenWidth="Tablet"
demandPopin="true"><Text text="{i18n>Region}"/></Column>
            <Column id="postalCodeCol" minScreenWidth="Tablet"
demandPopin="true"><Text text="{i18n>PostalCode}"/></Column>
            <Column id="countryCol" minScreenWidth="Tablet"
demandPopin="true"><Text text="{i18n>Country}"/></Column>
            <Column id="homePhoneCol" minScreenWidth="Tablet" demandPopin="true"
hAlign="Right"><Text text="{i18n>Phone}"/></Column>
        </columns>
        <items>
            <ColumnListItem>
                <cells>
                    <Text text="{EmployeeID}"/>
```

```
                    <Text text="{FirstName}"/>
                    <Text text="{LastName}"/>
                    <Text text="{Address}"/>
                    <Text text="{City}"/>
                    <Text text="{Region}"/>
                    <Text text="{PostalCode}"/>
                    <Text text="{Country}"/>
                    <Text text="{HomePhone}"/>
                </cells>
            </ColumnListItem>
        </items>
    </Table>
</mvc:View>
```

Create the file EmployeeOverviewContent.view.xml in the `webapp/view/employee/overview` folder. This view displays a responsive table with several columns containing employee data like *Employee ID*, *First Name*, *Last Name* and so on. In the `headerToolbar`, we add the `SearchField` and a `Button`. The `SearchField` in the header area allows to search in the table. The `Button` next to it opens a dialog to adjust the sorting of the table.

webapp/controller/employee/overview/ EmployeeOverviewContent.controller.js (New)

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    "sap/ui/model/Sorter",
    "sap/m/ViewSettingsDialog",
    "sap/m/ViewSettingsItem"
], function(
    BaseController,
    Filter,
    FilterOperator,
    Sorter,
    ViewSettingsDialog,
    ViewSettingsItem
) {
    "use strict";

    return
BaseController.extend("sap.ui.demo.nav.controller.employee.overview.EmployeeOverv
iewContent", {

sorting
         * @param {string} sortDescending    true or false as a string or
boolean value to specify a descending sorting
         * @private
```

```
         */
        _applySorter : function (sSortField, sortDescending){
            var bSortDescending, oBinding, oSorter;

            // only continue if we have a valid sort field
            if (sSortField && this._aValidSortFields.indexOf(sSortField) > -1) {

                // convert  the sort order to a boolean value
                if (typeof sortDescending === "string") {
                    bSortDescending = sortDescending === "true";
                } else if (typeof sortDescending === "boolean") {
                    bSortDescending =  sortDescending;
                } else {
                    bSortDescending = false;
                }

                // sort only if the sorter has changed
                if (this._sSortField && this._sSortField === sSortField &&
this._bSortDescending === bSortDescending) {
                    return;
                }

                this._sSortField = sSortField;
                this._bSortDescending = bSortDescending;
                oSorter = new Sorter(sSortField, bSortDescending);

                // sync with View Settings Dialog
                this._syncViewSettingsDialogSorter(sSortField, bSortDescending);

                oBinding = this._oTable.getBinding("items");
                oBinding.sort(oSorter);
            }
        },

        _syncViewSettingsDialogSorter : function (sSortField, bSortDescending) {
            // the possible keys are: "EmployeeID" | "FirstName" | "LastName"
            // Note: no input validation is implemented here
            this._oVSD.setSelectedSortItem(sSortField);
            this._oVSD.setSortDescending(bSortDescending);
        }

    });

});
```

Finally create the controller for the *Employee Overview* page in the `webapp/controller/employee/overview` folder. It basically sets up a `ViewSettingsDialog` to sort and filter the table of employees and implements event handlers for the search field and for the sorting of the table.

There is nothing special about this implementation. If you are interested in how to set up a table with sorting and filtering you can check the corresponding steps of the *Walkthrough* tutorial or the examples in the Demo Kit. We will mainly make use of the UI and the functionality for showing additional navigation and routing features. Therefore, we suggest copying the code and trying it out.

Open `webapp/index.html#/employees/overview` and check the new views. As you can see, the three views are wired together automatically by the router based on our configuration in the descriptor. In the top area of the page, you see a static text and below you see the table filled with data from our test service. The whole routing functionality that we see in this example is implemented by referencing two targets from one route.

Of course, you can also search the table and change the sorting. When the sorting dialog opens, it creates a block layer so that the back button and other controls cannot be accessed. However, you can still use the back button of the browser. As you can see, the dialog is closed automatically by the router before navigating.

> **i Note**
>
> The default behavior of the `sap.m` router is that all dialogs are closed when the hash changes (i.e. when calling `navTo`, `display` or pressing the back button of the browser). You can change this default behavior by calling `getTargetHandler().setCloseDialogs(false)` on the router or on the `Targets` object.

However, we have one problem yet to solve: the search and table ordering are not bookmarkable. Fortunately, we have additional navigation features at hand and you will see how this works in the next steps

webapp/i18n/i18n.properties

```
...
EmployeeOverview=Employee Overview
ShowEmployeeOverview=Show Employee Overview

EmployeeOverviewTop=Employee Overview Top

Region=Region
EmployeeID=Employee ID
Phone=Phone
Employees=Employees
```

Add the new texts to the `properties` file.

Step 12: Make a Search Bookmarkable

In this step we will make the search bookmarkable. This allows users to search for employees in the *Employees* table and they can bookmark their search query or share the URL.

Preview

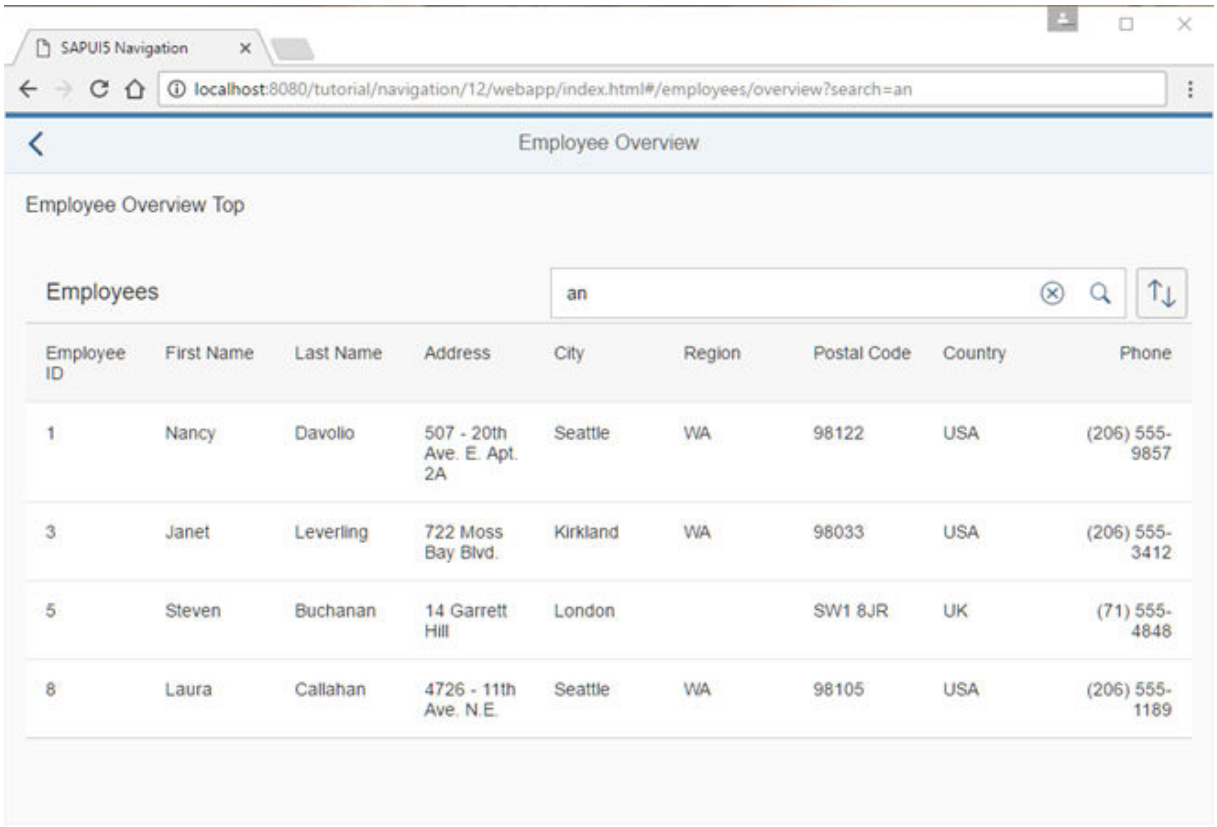

Figure 102: Search and sorting bookmarkable

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 12 .

webapp/manifest.json

```

            }, {
                "pattern": "employees",
                "name": "employeeList",
                "target": "employees"
            }, {
                "pattern": "employees/overview:?query:",
                "name": "employeeOverview",
                "target": ["employeeOverviewTop", "employeeOverviewContent"]
            }, {
                "pattern": "employees/{employeeId}",
                "name": "employee",
                "target": "employee"
            }, {
                "pattern": "employees/{employeeId}/resume:?query:",
                "name": "employeeResume",
                "target": "employeeResume"
            }],
            "targets": {
                ...
            }
        }
    }
}
```

In order to make the search bookmarkable we have to think about how the pattern of the corresponding route should match the bookmark. We decide to allow `/#/employees/overview?search=mySearchQueryString` in order to bookmark a search. Therefore, we simply extend our routing configuration a little. We add the optional `:?query:` parameter to the route `employeeOverview`. We keep in mind that we want to use `search` as the URL parameter for the search term that was entered in the search field.

webapp/controller/employee/overview/EmployeeOverviewContent.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    "sap/ui/model/Sorter",
    "sap/m/ViewSettingsDialog",
```

```
    "sap/m/ViewSettingsItem"
], function(
    BaseController,
    Filter,
    FilterOperator,
    Sorter,
    ViewSettingsDialog,
    ViewSettingsItem
) {
    "use strict";
    return
BaseController.extend("sap.ui.demo.nav.controller.employee.overview.EmployeeOverv
iewContent", {
        onInit: function () {
            var oRouter = this.getRouter();
            this._oTable = this.byId("employeesTable");
            this._oVSD = null;
            this._sSortField = null;
            this._bSortDescending = false;
            this._aValidSortFields = ["EmployeeID", "FirstName", "LastName"];
            this._sSearchQuery = null;
            this._oRouterArgs = null;
            this._initViewSettingsDialog();
            // make the search bookmarkable

oRouter.getRoute("employeeOverview").attachMatched(this._onRouteMatched, this);
        },
        _onRouteMatched: function (oEvent) {
            // save the current query state
            this._oRouterArgs = oEvent.getParameter("arguments");
            this._oRouterArgs["?query"] = this._oRouterArgs["?query"] || {};

            // search/filter via URL hash
            this._applySearchFilter(this._oRouterArgs["?query"].search);
        },
        onSortButtonPressed : function (oEvent) {
            this._oVSD.open();
        },
        onSearchEmployeesTable : function (oEvent) {
            var oRouter = this.getRouter();
            // update the hash with the current search term
            this._oRouterArgs["?query"].search = oEvent.getSource().getValue();
            oRouter.navTo("employeeOverview", this._oRouterArgs, true /*no
history*/);
        },
        ...
    });
});
```

Now we handle the optional query parameter from the `employeeOverview` route in our `EmployeeOverviewContent` controller. First we change the `onInit` function by adding an event listener for the matched event of the `employeeOverview` route. Then we buffer the current router arguments as received from the event. If a query is available, the result from `oEvent.getParameter("arguments")` will contain a `?query` property with an object of all URL parameters specified, otherwise it is undefined. If no query parameter is defined, we always initialize the query and save it to `this._oRouterArgs["?query"]`. If we have a search term query at the `search` key we continue and call `this._applySearchFilter(this._oRouterArgs["?query"].search)` to trigger a search based on the search query parameter from the URL.

Storing the `arguments` objects internally in the controller is important, because we will use the current arguments when calling `navTo()` in the search event handler `onSearchEmployeesTable` and pass on the arguments with the updated search term. We keep the URL and the UI in sync by navigating to the current target again with the current value of the search field from the event's source. The search value is stored in

`this._oRouterArgs["?query"].search` together with the other query parameters and it is passed directly to the router again

That's it, now our search is bookmarkable and reflected in the URL. Try to access the following pages in your browser:

- `webapp/index.html#/employees/overview`
- `webapp/index.html#/employees/overview?search=`
- `webapp/index.html#/employees/overview?search=an`

When you change the value in the search field, you see that the hash updates accordingly.

Step 13: Make Table Sorting Bookmarkable

In this step, we will create a button at the top of the table which will change the sorting of the table. When the current sorting state of the table is changed, the sorting state will be reflected in the URL. This illustrates how to make the table sorting bookmarkable.

Preview

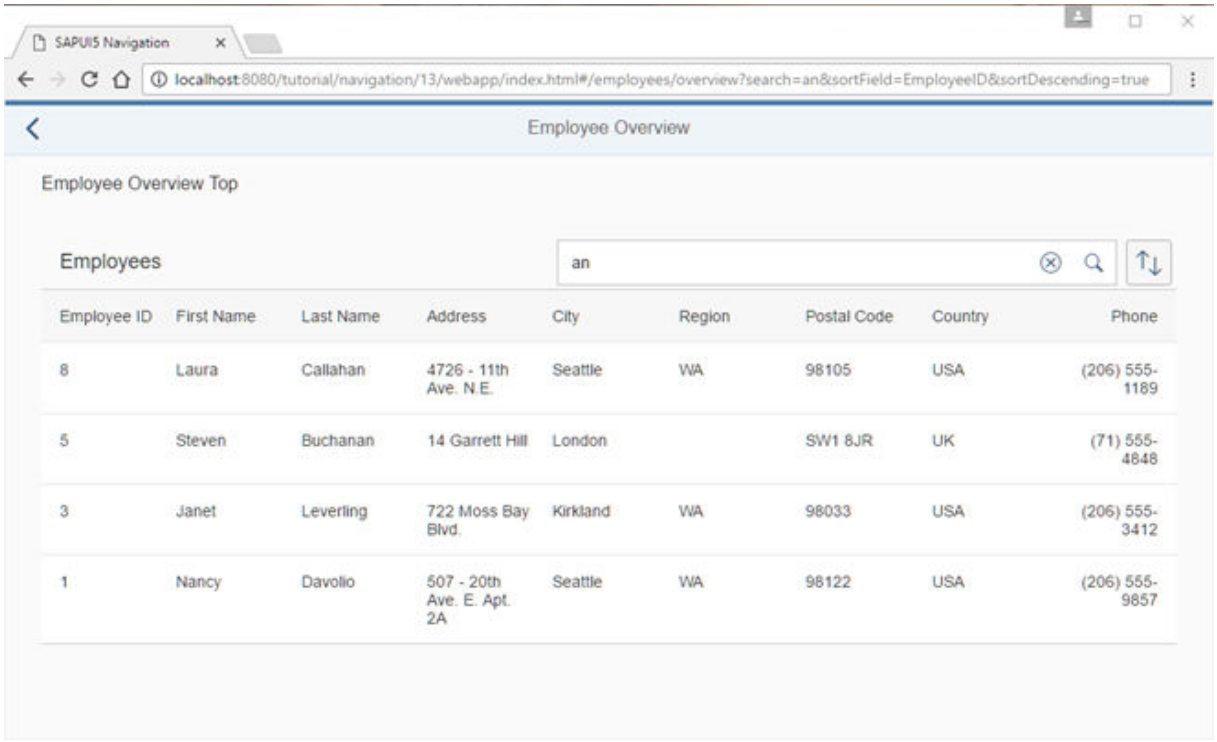

Figure 103: Bookmarkable search and sorting

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 13.

webapp/controller/employee/overview/EmployeeOverviewContent.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    "sap/ui/model/Sorter",
    "sap/m/ViewSettingsDialog",
    "sap/m/ViewSettingsItem"
], function(
    BaseController,
    Filter,
    FilterOperator,
    Sorter,
    ViewSettingsDialog,
    ViewSettingsItem
) {
    "use strict";
    return
BaseController.extend("sap.ui.demo.nav.controller.employee.overview.EmployeeOverv
iewContent", {
        onInit: function () {
            ...
        },
        _onRouteMatched: function (oEvent) {
            // save the current query state
            this._oRouterArgs = oEvent.getParameter("arguments");
            this._oRouterArgs["?query"] = this._oRouterArgs["?query"] || {};
            var oQueryParameter = this._oRouterArgs["?query"];
            // search/filter via URL hash
            this._applySearchFilter(oQueryParameter.search);
            // sorting via URL hash
            this._applySorter(oQueryParameter.sortField,
oQueryParameter.sortDescending);

        },
        ...
        _initViewSettingsDialog: function () {
            var oRouter = this.getRouter();
            this._oVSD = new sap.m.ViewSettingsDialog("vsd", {
                confirm: function (oEvent) {
                    var oSortItem = oEvent.getParameter("sortItem");
                    this._oRouterArgs["?query"].sortField = oSortItem.getKey();
                    this._oRouterArgs["?query"].sortDescending =
oEvent.getParameter("sortDescending");
                    oRouter.navTo("employeeOverview", this._oRouterArgs, true /
*without history*/);
                }.bind(this)
            });
            ...
        },
        ...
    });
});
```

We enhance the `EmployeeOverviewContent` controller further to add support for bookmarking the table's sorting options. We expect two query parameters `sortField` and `sortDescending` from the URL for configuring the sorting of the table. In the matched handler of the route `employeeOverview`, we store the query parameter in the `oQueryParameter` variable and add an additional call to `this._applySorter(oQueryParameter.sortField, oQueryParameter.sortDescending)`. This

triggers the sorting action based on the two query parameters `sortField` and `sortDescending` from the URL.

Next we change the `confirm` event handlers of our `ViewSettingsDialog`. The `confirm` handler updates the current router arguments with the parameters from the event accordingly. Then we call `oRouter.navTo("employeeOverview", this._oRouterArgs, true)` with the updated router arguments to persist the new sorting parameters in the URL. Both the previous arguments (i.e. `search`) and the new arguments for the sorting will then be handled by the matched event handler for the `employeeOverview` route.

Congratulations! Even the sorting options of the table can now be bookmarked. Try to access the following pages:

- `webapp/index.html#/employees/overview?sortField=EmployeeID&sortDescending=true`
- `webapp/index.html#/employees/overview?search=an&sortField=EmployeeID&sortDescending=true`

When changing the table's sorting options, you will see that the hash updates accordingly.

Step 14: Make Dialogs Bookmarkable

In this step, we want to allow bookmarking of the dialog box that is opened when the user clicks the *Sort* button. The dialog should automatically open when the URL contains the query parameter `showDialog`.

Preview

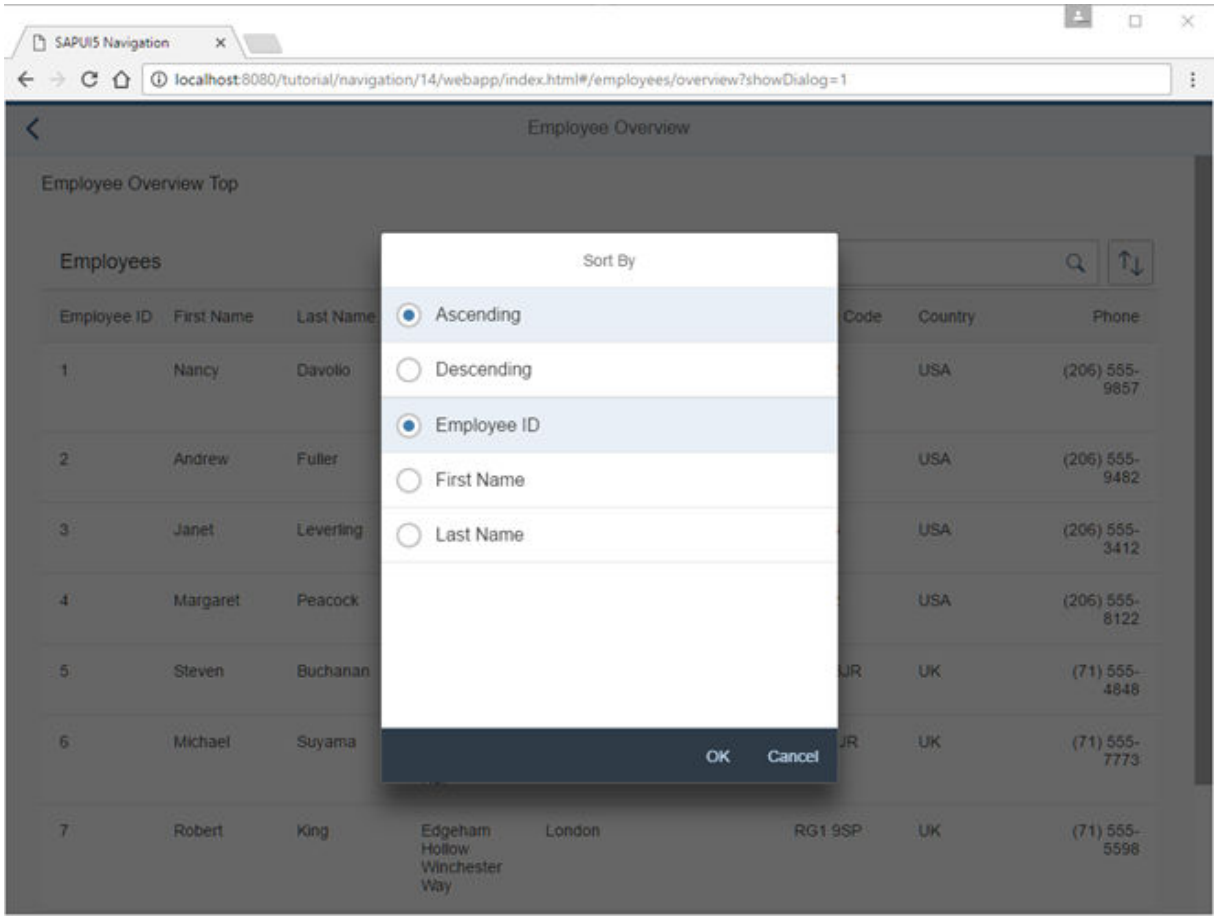

Figure 104: Bookmark for a dialog

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 14.

/controller/employee/overview/EmployeeOverviewContent.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController",
```

```
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    "sap/ui/model/Sorter",
    "sap/m/ViewSettingsDialog",
    "sap/m/ViewSettingsItem"
], function(
    BaseController,
    Filter,
    FilterOperator,
    Sorter,
    ViewSettingsDialog,
    ViewSettingsItem
) {
    "use strict";
    return
BaseController.extend("sap.ui.demo.nav.controller.employee.overview.EmployeeOverv
iewContent", {
        onInit: function () {
            ...
        },
        _onRouteMatched: function (oEvent) {
            // save the current query state
            this._oRouterArgs = oEvent.getParameter("arguments");
            this._oRouterArgs["?query"] = this._oRouterArgs["?query"] || {};
            var oQueryParameter = this._oRouterArgs["?query"];
            // search/filter via URL hash
            this._applySearchFilter(oQueryParameter.search);
            // sorting via URL hash
            this._applySorter(oQueryParameter.sortField,
oQueryParameter.sortDescending);
            // show dialog via URL hash
            if (oQueryParameter.showDialog) {
                this._oVSD.open();
            }

        },
        onSortButtonPressed: function (oEvent) {
            var oRouter = this.getRouter();
            this._oRouterArgs["?query"].showDialog = 1;
            oRouter.navTo("employeeOverview", this._oRouterArgs);
        },
        ...
        _initViewSettingsDialog: function () {
            var oRouter = this.getRouter();
            this._oVSD = new sap.m.ViewSettingsDialog("vsd", {
                confirm: function (oEvent) {
                    var oSortItem = oEvent.getParameter("sortItem");
                    this._oRouterArgs["?query"].sortField = oSortItem.getKey();
                    this._oRouterArgs["?query"].sortDescending =
oEvent.getParameter("sortDescending");
                    delete this._oRouterArgs["?query"].showDialog;
                    oRouter.navTo("employeeOverview", this._oRouterArgs, true /
*without history*/);
                }.bind(this),
                cancel: function (oEvent){
                    delete this._oRouterArgs.query.showDialog;
                    oRouter.navTo("employeeOverview", this._oRouterArgs, true /
*without history*/);
                }.bind(this)
            });
            ...
        },
        ...
    });
});
```

Once again we will update the `EmployeeOverviewContent` controller to add support for the bookmarking of our sorting dialog. We decide to choose a query parameter `showDialog` that controls if the dialog is opened directly when we navigate to the page with a deep link. Therefore, we extend the matched event handler for the `employeeOverview` route. If the query parameter `showDialog` is set to `1`, we open the dialog. We only have to make sure that the dialog does not get closed again by the router as this behavior is the default when navigating.

Next we change the `press` handler of the sort button. In the `onSortButtonPressed` function we set `this._oRouterArgs["?query"].showDialog = 1` and call `navTo()` to let the router do the job instead of directly opening the dialog. Finally, we delete `this._oRouterArgs["?query"].showDialog` before calling `navTo()` in the `confirm` and `cancel` event handlers of the `ViewSettingsDialog`. This is important to make sure that the dialog does not open again by the matched handler.

We are now done with this step. Try to access the following pages:

- `webapp/index.html#/employees/overview?showDialog=1`
- `webapp/index.html#/employees/overview?search=an&sortField=EmployeeID&sortDescending=true&showDialog=1`

As you can see, the dialog opens automatically if the parameter `showDialog=1` is added to the URL. That's exactly what we wanted.

Step 15: Reuse an Existing Route

The *Employees* table displays employee data. However, the resumes of the employees are not accessible from this view yet. We could create a new route and a new view to visualize the resume again, but we could also simply reuse an existing route to cross-link the resume of a certain employee. In this step, we will add a feature that allows users to directly navigate to the resume of a certain employee. We will reuse the *Resume* page that we have created in an earlier step. This example illustrates that there can be multiple navigation paths that direct to the same page.

Preview

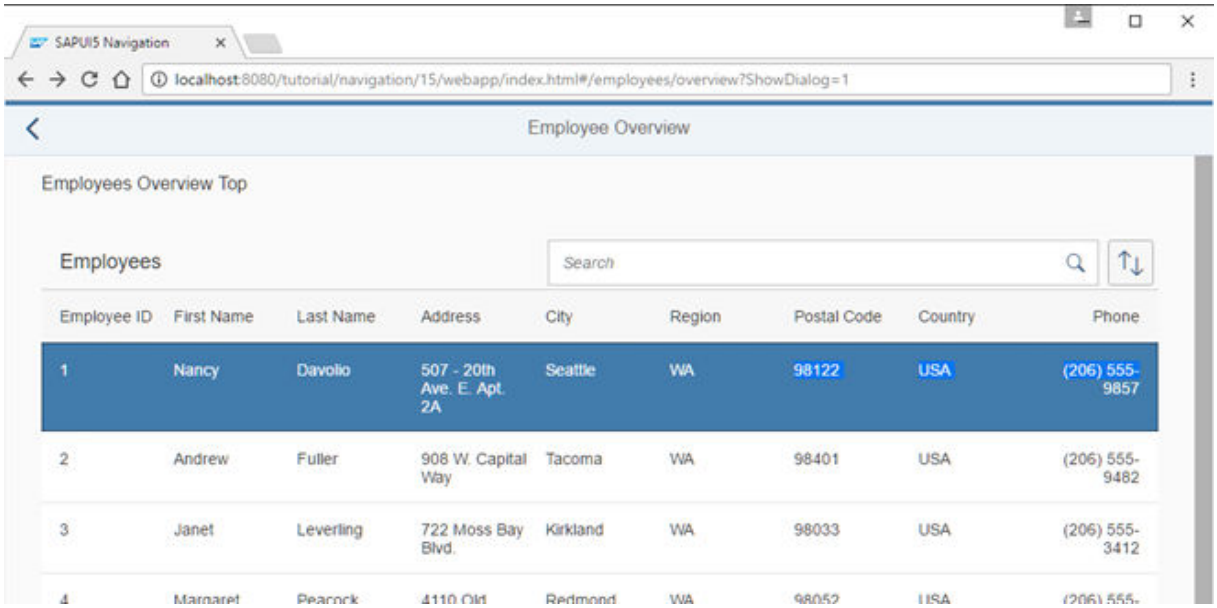

Figure 105: Navigation to an existing route from a table item

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 15.

webapp/view/employee/overview/EmployeeOverviewContent.view.xml

```
<mvc:View

controllerName="sap.ui.demo.nav.controller.employee.overview.EmployeeOverviewCont
ent"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Table id="employeesTable"
        items="{/Employees}"
            itemPress=".onItemPressed">
        <headerToolbar>
            ...
        </headerToolbar>
        <columns>
            ...
        </columns>
        <items>
            <ColumnListItem type="Active">
                <cells>
                    ...
                </cells>
            </ColumnListItem>
        </items>
    </Table>
</mvc:View>
```

In the `EmployeeOverviewContent` view we register an event handler for the `itemPress` event and set the type attribute of the `ColumnListItem` to `Active` so that we can choose an item and trigger the navigation.

webapp/controller/employee/overview/EmployeeOverviewContent.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    "sap/ui/model/Sorter",
    "sap/m/ViewSettingsDialog",
    "sap/m/ViewSettingsItem"
], function(
    BaseController,
    Filter,
    FilterOperator,
    Sorter,
    ViewSettingsDialog,
    ViewSettingsItem
) {
    "use strict";
    return
BaseController.extend("sap.ui.demo.nav.controller.employee.overview.EmployeeOverv
iewContent", {
        ...
        _syncViewSettingsDialogSorter: function (sSortField, bSortDescending) {
            // the possible keys are: "EmployeeID" | "FirstName" | "LastName"
            // Note: no input validation is implemented here
            this._oVSD.setSelectedSortItem(sSortField);
            this._oVSD.setSortDescending(bSortDescending);
        },
        onItemPressed: function (oEvent) {
            var oItem, oCtx, oRouter;
            oItem = oEvent.getParameter("listItem");
            oCtx = oItem.getBindingContext();
            this.getRouter().navTo("employeeResume",{
                employeeId : oCtx.getProperty("EmployeeID"),
                "?query": {
                    tab: "Info"
                }
            });
        }
    });
});
```

Next we add the `itemPress` handler `.onItemPressed` to the `EmployeeOverviewContent` controller. It reads from the binding context which item has been chosen and navigates to the `employeeResume` route. We have already added this route and the corresponding target in a previous step and can now reuse it. From now on it is possible to navigate to the `employeeResume` route from our employee table as well as from the employee detail page created in an earlier step (the route name is `employee`).

Step 16: Handle Invalid Hashes by Listening to Bypassed Events

So far we have created many useful routes in our app. In the very early steps we have also made sure that a *Not Found* page is displayed in case the app was called with an invalid hash. Now, we proceed further and track invalid hashes to be able to detect and correct any invalid links or add new URL patterns that are often requested but not found. Therefore, we simply listen to the bypassed events

Preview

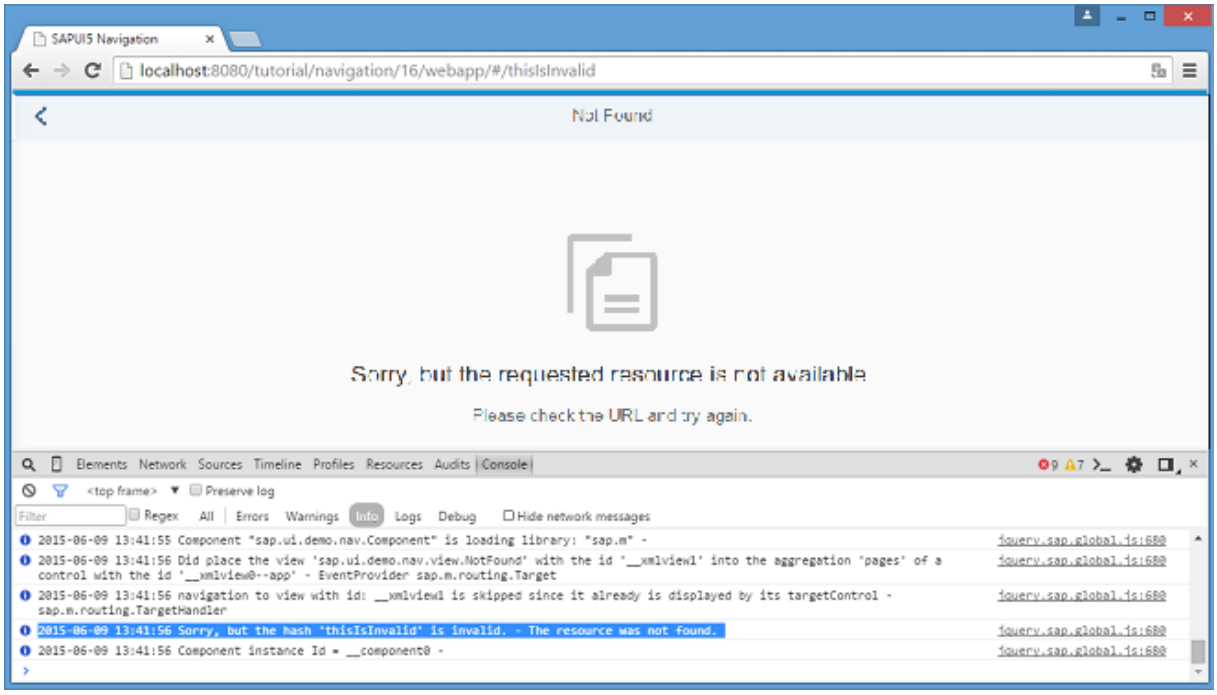

Figure 106: Console output for invalid hashes when listening to bypassed events

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 16.

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController"
], function (BaseController) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.App", {
        onInit: function () {
```

```
            // This is ONLY for being used within the tutorial.
            // The default log level of the current running environment may be
higher than INFO,
            // in order to see the debug info in the console, the log level
needs to be explicitly
            // set to INFO here.
            // But for application development, the log level doesn't need to be
set again in the code.
            Log.setLevel(Log.Level.INFO);

            var oRouter = this.getRouter();

            oRouter.attachBypassed(function (oEvent) {
                var sHash = oEvent.getParameter("hash");
                // do something here, i.e. send logging data to the backend for
analysis
                // telling what resource the user tried to access...
                Log.info("Sorry, but the hash '" + sHash + "' is invalid.", "The
resource was not found.");
            });
        }
    });
});
```

All we need to do is listen to the bypassed event on the router. If the bypassed event is triggered, we simply get the current hash and log a message. In an actual app this is probably the right place to add some application analysis features, i.e. sending analytical logs to the back end for later evaluation and processing. This could be used to improve the app, for example, to find out why the user called the app with an invalid hash.

> **i Note**
>
> We have chosen to place this piece of code into the `App` controller because this is a global feature of the app. However, you could also place it anywhere else, for example in the `NotFound` controller file or in a helper module related to analysis.

Now try to access `webapp/index.html#/thisIsInvalid` while you have your browser console open. As you can see, there is a message that issues a faulty hash. Furthermore, our `NotFound` page is displayed.

Related Information

API Reference: `sap.m.routing.Router`

Step 17: Listen to Matched Events of Any Route

In the previous step, we have listened for bypassed events to detect possible technical issues with our app. In this step, we want to improve the analysis use case even more by listening to any matched event of the route. We could use this information to measure how the app is used and how frequently the pages are called. Many Web analytic tools track page hits this way. The collected information can be used, for example to improve our app and its usability.

Preview

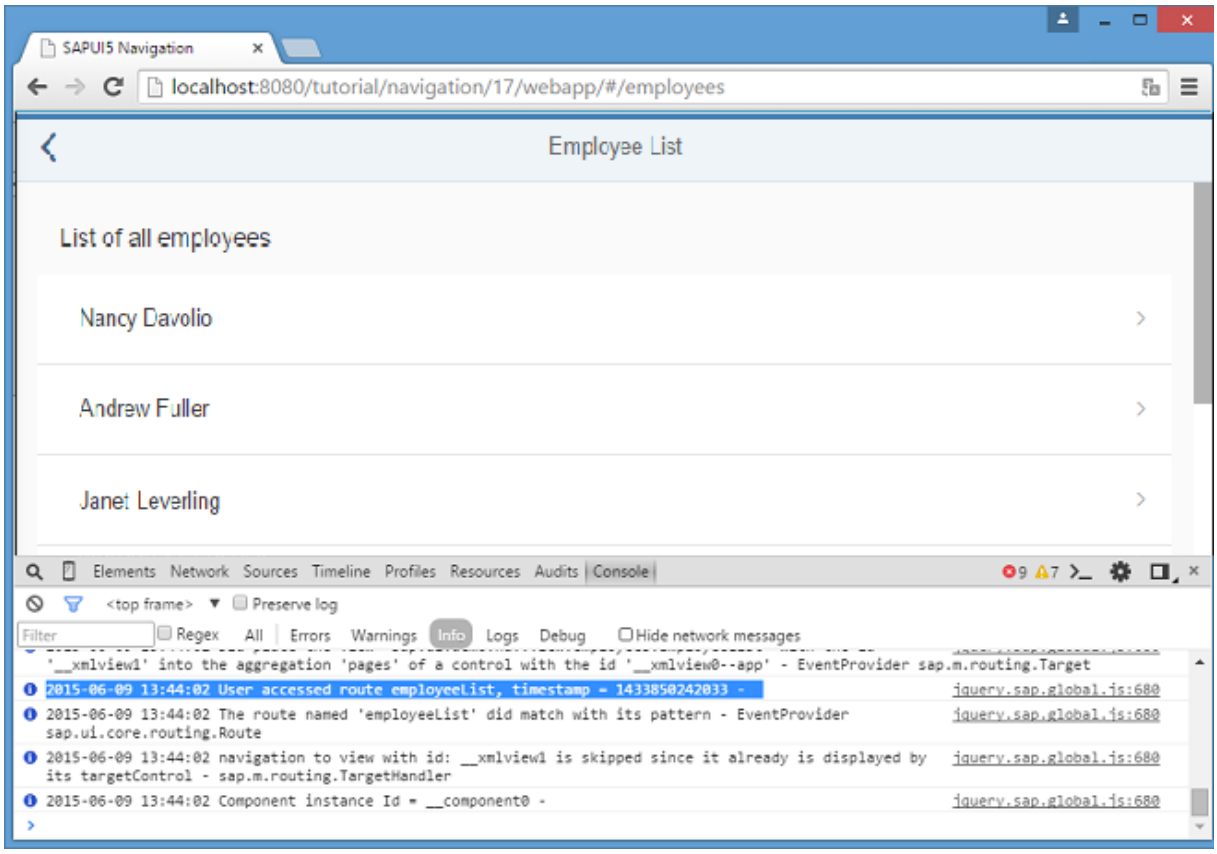

Figure 107: Console output for routes matched by listening to `routeMatched` events

Coding

You can view and download all files in the *Samples* in the Demo Kit at Routing and Navigation - Step 17.

webapp/controller/App.controller.js

```
sap.ui.define([
    "sap/ui/demo/nav/controller/BaseController",
    "sap/base/Log"
], function (BaseController, Log) {
    "use strict";
    return BaseController.extend("sap.ui.demo.nav.controller.App", {
        onInit: function () {
            var oRouter = this.getRouter();
            oRouter.attachBypassed(function (oEvent) {
                var sHash = oEvent.getParameter("hash");
                // do something here, i.e. send logging data to the back end for
analysis
                // telling what resource the user tried to access...
                Log.info("Sorry, but the hash '" + sHash + "' is invalid.", "The
resource was not found.");
```

```
            });
            oRouter.attachRouteMatched(function (oEvent){
                var sRouteName = oEvent.getParameter("name");
                // do something, i.e. send usage statistics to back end
                // in order to improve our app and the user experience (Build-
Measure-Learn cycle)
                Log.info("User accessed route " + sRouteName + ", timestamp = "
+ new Date().getTime());
            });
        }
    });
});
```

We extend the `App` controller again and listen to the `routeMatched` event. The `routeMatched` event is thrown for any route that matches to our route configuration in the descriptor file. In the event handler, we determine the name of the matched route from the event parameters and log it together with a time stamp. In an actual app, the information could be sent to a back-end system or an analytics server to find out more about the usage of your app.

Now you can access, for example, `webapp/index.html#/employees` while you have the console of the browser open. As you can see, there is a message logged for each navigation step that you do within the app.

Testing

In this tutorial we will test application functionality with the testing tools that are delivered with SAPUI5. At different steps of this tutorial you will write tests using QUnit, OPA5, and the mock server. Additionally, you will learn about testing strategies, Test Driven Development (TDD), and much more.

For the application features that we add, we focus on writing clean and testable code with the goal of having good test coverage and a high quality app. We will create a simple full screen app that we will extend with more tests and features throughout the tutorial.

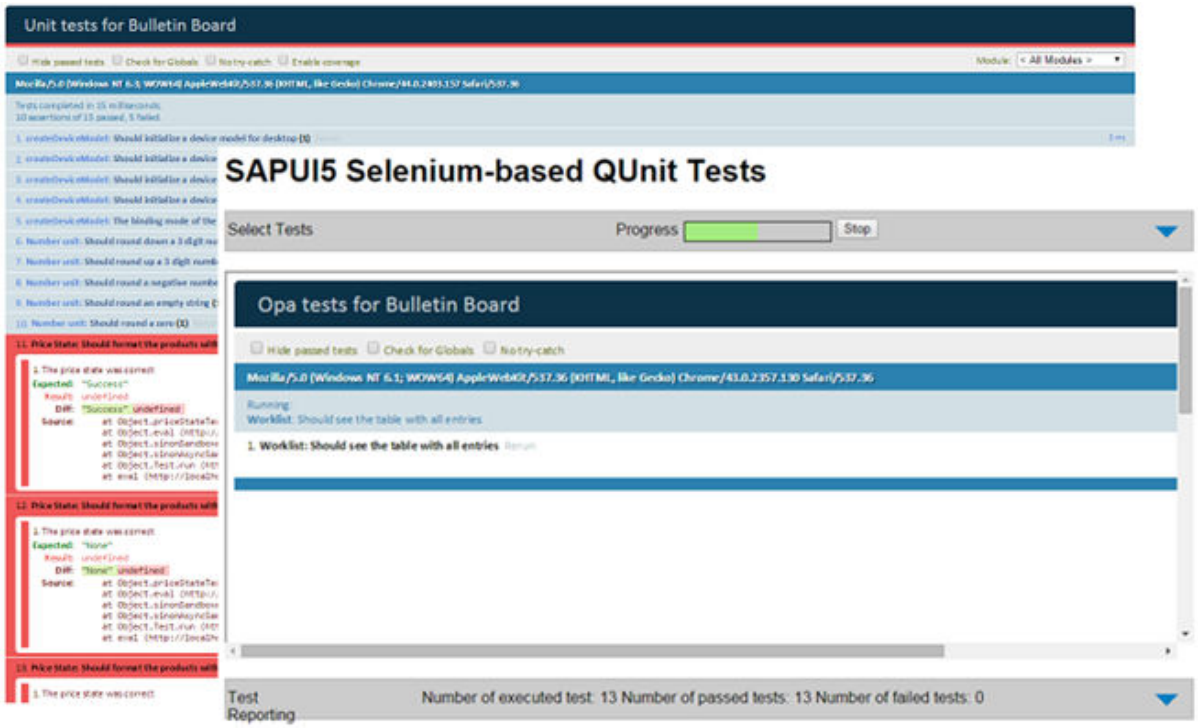
Imagine the following situation: You and your development team take over a bulletin board prototype that will be shipped as a product soon. A bulletin board typically consists of functionality to browse posts and add own offers to the board. However, the prototype only covers a minimum set of features and tests so far.

With this very minimalistic app as a starting point, we have a good foundation and we can inspect the most important testing functionality. Furthermore, we want to implement new features for the app that were requested by the product team using Test Driven Development and best practices for writing testable code and testing SAPUI5 apps.

So why do we do all this? Obviously, writing tests and testable code does not come without effort. Well, we want to ensure the implementation of a high quality app by having decent test coverage of our application logic. And we check that our code does not break by running the automated tests whenever we change something or when we upgrade to a newer version of the SAPUI5 framework or other external libraries. Additionally, we can find bugs proactively and do not need excessive manual testing anymore so the efforts definitely pay off. Also, when we decide to refactor something in the future, we can easily verify that the features of the app are still working as expected.

There are a lot more reasons and many small details that we will address throughout this tutorial. You can work yourself through the steps by applying the code deltas individually or by downloading the samples for each step and playing around with it.

Preview



Prerequisites

In addition to the prerequisites that are presupposed for all our tutorials (see Prerequisites [page 38]), you should also be familiar with the basics of JavaScript unit testing with QUnit. Have a look at the official QUnit documentation to make yourself familiar with basic testing knowledge. Steps 27 to 29 of the Walkthrough tutorial also cover the test setup in an app that is used throughout this tutorial.

If you want to automate the test execution using a test runner, you can set this up as described under Test Automation [page 1229].

> → Tip
>
> You don't have to do all tutorial steps sequentially, you can also jump directly to any step you want. Just download the code from the previous step, and start there.
>
> You can view and download the files for all steps in the Demo Kit at Testing Apps. Copy the code to your workspace and make sure that the application runs by calling the `webapp/test/test.html` file. Depending on your development environment you might have to adjust resource paths and configuration entries.
>
> For more information check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):
>
> - Downloading Code for a Tutorial Step [page 40]

- Adapting Code to Your Development Environment [page 40]

Related Information

Testing [page 1158]
QUnit Home Page

Step 1: Overview and Testing Strategy

In this step, we will take a look at the prototype and define the test strategy for our app. The prototype already contains the infrastructure for unit and integration testing and a minimum set of tests and features.

> **i Note**
>
> In this tutorial we will focus on writing clean unit and integration tests for apps. They build the foundation and are crucial for good application quality. We will also outline how to write testable code. Not all implementation patterns can be tested easily, but when writing the test code together with the implementation code as we have in this tutorial, testable code is a natural result.

Preview

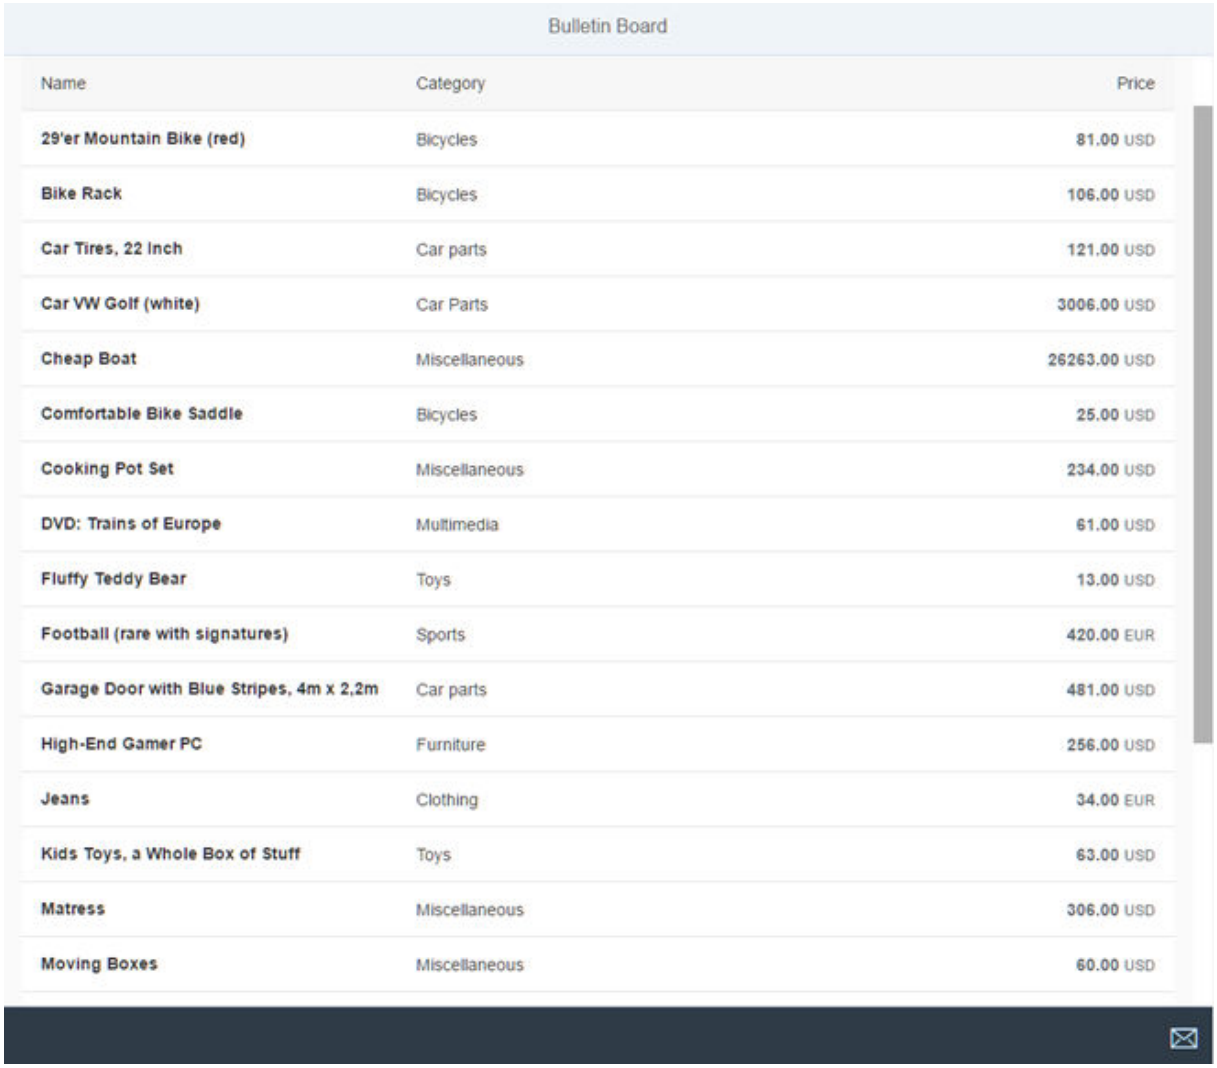


Figure 108: The prototype app

Coding

To set up your project for this tutorial, download the files for *Step 1* from the *Samples* in the Demo Kit at Testing - Step 1. Copy the code to your workspace and make sure that the application runs by calling the `webapp/test/mockServer.html` file.

Depending on your development environment, you might have to adjust resource paths and configuration entries. The project structure and the files provided with this tutorial are explained in detail in the Walkthrough [page 69] tutorial.

After downloading *Step 1*, you should have the following files:

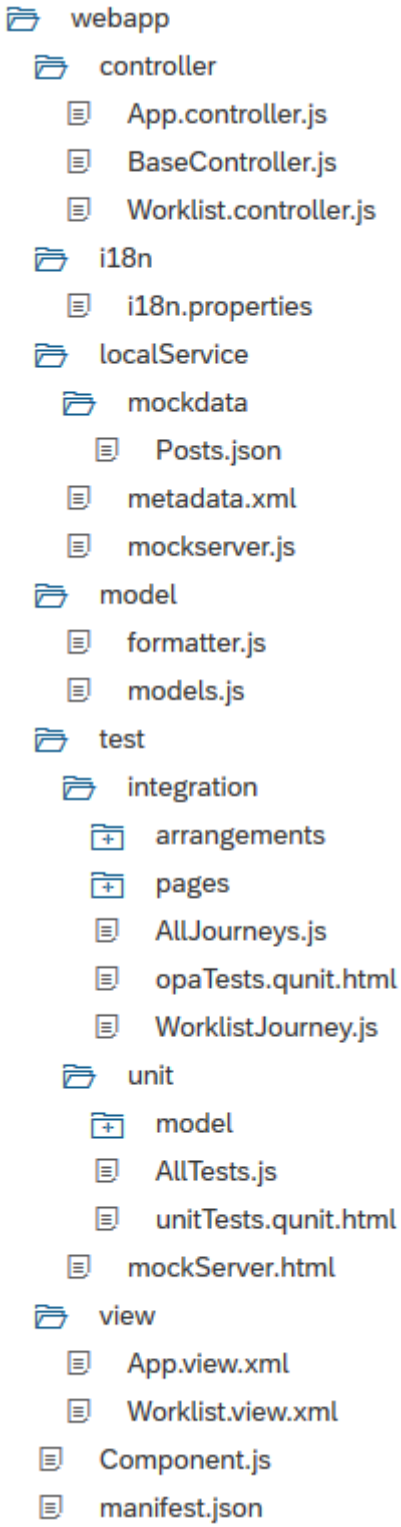

Figure 109: Folder structure with downloaded files

The Initial App

With the downloaded code, you now have the bulletin board prototype, set up according to the SAPUI5 best practices. The prototype provides the common features of an SAPUI5 app. If you have completed the Walkthrough tutorial, you should be familiar with most of the source code in this step. Additional features of the app are:

- **Entry Page**
  In this tutorial, we will often switch between testing application features manually, and running automated tests. The `webapp/test/test.html` file provides a list of entry points for the app so that you do not have to enter the URLs manually. From this page you can open the app with mock data, run the unit tests, run the integration tests, or run the app's test suite (this will be added later in the tutorial). Note that in a productive scenario we would have an additional entry point that calls the app with a real service. At this stage we are working with mock data and don't have a real service for our prototype yet, so we have left this step out.
- **Home Page**
  The home page of our bulletin board app is the `webapp/test/mockServer.html` file. On this page, we initialize SAPUI5, start the mock server, and instantiate our app component. It consists of a single view that displays a list of posts from a bulletin board with several attributes in a table.

  > **i** Note
  >
  > We do not yet have a real service for the bulletin board prototype so run the app with mock data and this test page throughout the tutorial. The mock server helps by mimicking a real service and it processes requests with a small delay, just as a real service would. This is perfect for realistic application testing and is also helpful for local development tests. It is a good practice to put all test pages in the test folder of the app, so that they are clearly separated from the productive coding.

- **Data**
  In the `webapp/localService/` folder, you can find the metadata and the mock data for the app. The `metadata.xml` file is used by the mock server to simulate real back-end service calls in the app. It describes our OData service and you can replace it later with a real service. The service we use has a single OData entity:
  - **Post**
    A post consists of typical properties like *Title*, *Description*, and *Price*. Each post is assigned to a *Category* and a *Contact*. The entity can be identified with its ID property: `PostID`. The corresponding `EntitySet` is `Posts`.
  - **Category**
    In our example, the category only has a `Name` property. Posts are sorted into a category by the category name. The corresponding `EntitySet` is `Categories`.
  - **Comment**
    A comment has an `Author`, a `Date`, and a `CommentText` property. The entity can be identified by the `CommentID` property and is linked to a `post` by the `ParentID`. The corresponding `EntitySet` is `Comments`.

  The actual test data containing several mock posts is located in the `webapp/test/service/posts.json` file.
- **Testing Functionality**
  The team that created the first prototype already took care of the basic test setup. Everything required for application testing is shipped with SAPUI5 and can simply be used within the app. The testing infrastructure is set up in the `test` folder that is located in the `webapp` folder of the app:

- **Mock Server**
  The mock server is set up in the `webapp/localService/mockserver.js` file. It loads the metadata and the mock data in the same folder. Using the mock server allows us to run the app easily and show realistic data for testing, even without a network connection and without the need of having a remote server for our application data.
  There is a configurable delay for each request that is processed by the mock server that allows you to mimick a slow back-end server.
- **Unit Tests**
  All unit tests are located in the `webapp/test/unit` folder and can be started by calling the `unitTests.qunit.html` file in the same folder. Initially, there are only a few tests for model instantiation and formatters that cover basic functionality in the prototype. We will give you more details about the unit test setup later in the tutorial.
- **Integration Tests**
  Integration tests are written in OPA5 – a tool for integration testing that is included in SAPUI5 – and can be found in the `webapp/test/integration` folder. You can start all OPA5 tests by calling the `opaTests.qunit.html` file in the same folder. OPA5 tests are organized in test journeys, and we have included a worklist journey that checks if the table of posts is displayed properly. We will give you more details about the integration test setup later in the tutorial.

- **Other quality-related features of the app**
  The app is set up according to best practices and already contains many helpful features.
  - **Separation of concerns (MVC)**
    All artifacts are located in either the `model`, `view`, or `controller` folder of the app. The app's component and its descriptor configure which of those MVC artifacts to load. This configuration controls the navigation flow of the app.
  - **Separation of productive and nonproductive code**
    All nonproductive code is located in the `test` subfolder. This includes the unit and integration tests, and the test page to call the app with mock data. All productive code is located in the `webapp` folder. This clearly separates the test artifacts from the application coding and makes it easy to remove all test-related artifacts before deploying the app for productive use.
  - **Busy handling**
    As a best practice, you should always give users instant feedback when triggering actions and navigating in the app. The app already includes functionality to display a busy indication when data is loaded or actions are triggered. To simulate a slow backend and show the behavior of the app, the mock server is configured with a delay of one second for each request.

Now that we have a running prototype, we can further extend it with additional tests and features. Make sure that the app is running by calling the test page, the unit tests, and the integration tests from the entry page `webapp/test/test.html`. The app should display a list of bulletin board posts as seen in the screenshot above and the tests should run without errors.

Test Strategy

Let's first take a look at best practices for testing apps written in SAPUI5. JavaScript is a dynamic programming language and only some issues can be detected by static code check tools and manual testing. Automated tests that execute the code regularly are beneficial for good quality and development productivity – especially when you're developing in short development cycles.

We expect our prototype to be released and shipped as a product soon, so we need a solid testing strategy. Fortunately the prototype team has already thought ahead and prepared an infrastructure for unit and

integration testing that is included in the app. This is a really good starting point for further enhancements of the app.

The mock server is also set up and allows us to test the app with local test data instead of a real back-end service. We can use the mock data for writing reliable integration tests that do not depend on another system which might be unavailable when the tests are run.

> **i Note**
>
> If you start developing an app from scratch, you should always consider testing from the very beginning of the software life cycle. Nobody wants to write tests for undocumented code and make assumptions about the logic. It is worth the effort to think about code checks, unit and integration testing, and a solid testing strategy from the very start.

Before you start implementing your first test, you should think about how to test the different aspects of your application. The image below shows the testing tools along the agile testing pyramid.

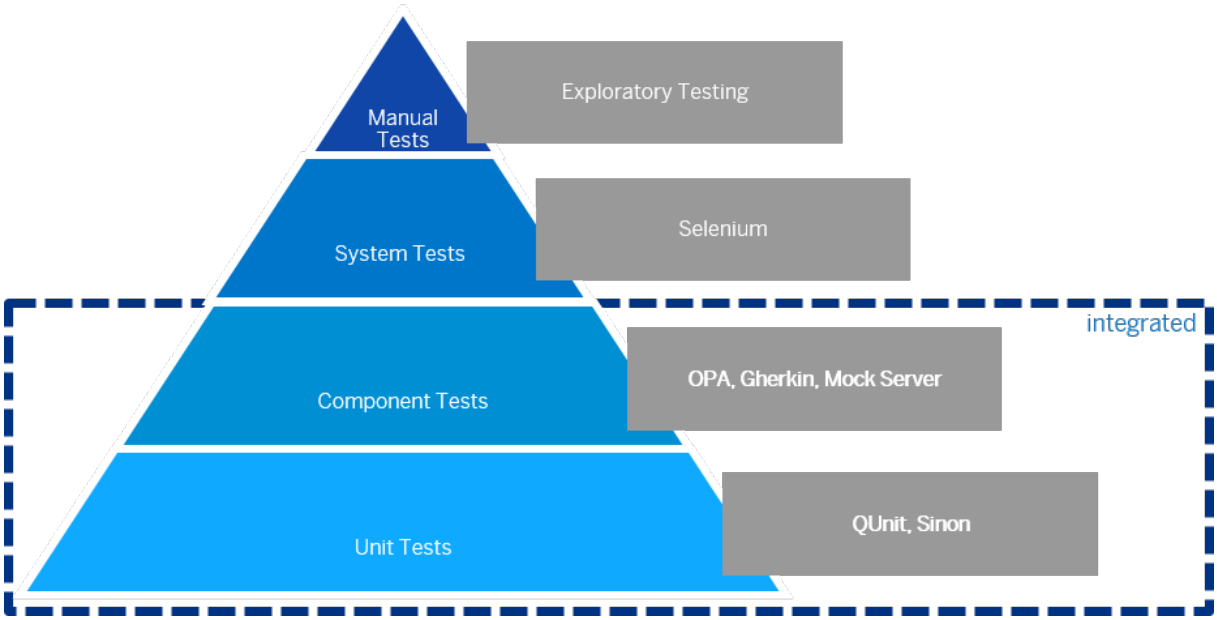

Figure 110: Testing pyramid

When you set up application testing, you should automate as many testing steps as possible. If you immediately write a test for all the features that we implement, then you can greatly reduce manual testing efforts that are time consuming and cumbersome. If you change something later, you can simply run the existing tests and see if the functionality is still working as expected.

SAPUI5 comes with two testing tools: QUnit for unit testing and OPA5 for integration testing. The unit tests are the foundation of our testing pyramid and they should validate the most important logic of our app. In addition, you can write integration tests for more interaction-related functionality, such as interacting with UI elements of the app.

There might still be features that are hard to test with these client-side testing frameworks. Certain features might require a more sophisticated system test, such as a screenshot comparison that can be implemented with additional testing frameworks. And of course, you should also schedule manual tests (for example, browser, performance, or security tests) to make sure that the app is behaving as expected.

Conventions

- Write unit tests in QUnit for more logic-related functionality
- Write integration tests in OPA5 for user interaction
- Separate productive and nonproductive code in the app (`webapp`, `test` folder)
- Provide a local test page that triggers the app in test mode with mock data (`test/mockServer.html`)

Step 2: A First Unit Test

In this step we will analyze the unit testing infrastructure and write a first unit test.

The product team requested a feature to highlight the price with colors depending on the amount. This can be done using the standard semantic colors that are defined for states like *Success*, *Warning*, or *Error*.

The price values can be mapped to semantic states as follows:

- price < 50: Status is green (*Success*)
- price >= 50 and price < 250: Status is normal (*None*)
- price >= 250 and price < 2000: Status is orange (*Warning*)
- price >= 2000: Status is red (*Error*)

As we use Test Driven Development (TDD) we define the test case first, before we actually implement the feature. So we will now start by implementing a test for the *Price State* feature. Naturally the test will fail until the feature is implemented in the next step.

> **i Note**
>
> Test Driven Development (TDD) is a software development model that relies on a very short development cycle. When using TDD a developer first writes a failing automatic test case to describe the behavior of a new feature or functionality. As soon as the test fails (due to the still missing implementation) the role of the developer switches to the implementation. The code is added to make the test run successful and then the cycle starts over again.
>
> There might also be iterations where just the implementation or testing code is refactored to make it more elegant. TDD reduces complexity while maintaining high test coverage of the application coding at the same time.

Preview

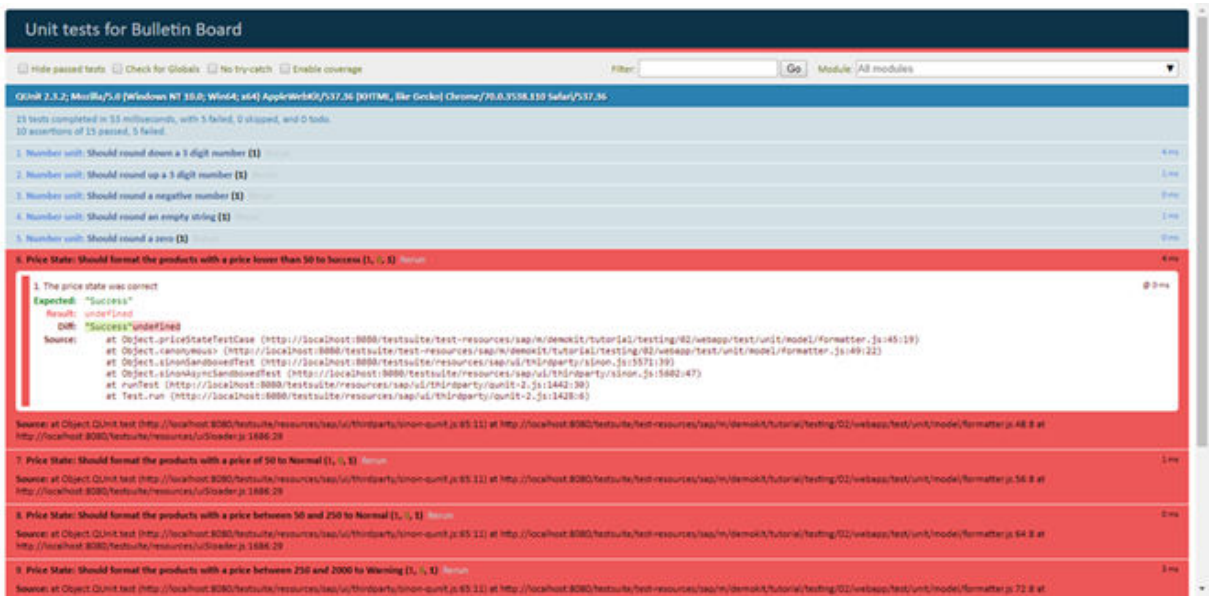

Figure 111: The unit test will initially fail as the implementation is not provided yet

Unit Test Setup

All unit tests are located in the `webapp/test/unit` folder and can be started manually by calling the `unitTests.qunit.html` file in the same folder or the entry page. This HTML page is a QUnit runner that calls all unit tests of the app and displays the test results in a readable format.

> ### i Note
>
> Some testrunners like Karma do not require an HTML page to invoke the tests but work with configuration files instead. They can directly invoke the `AllTests.js` file and log the test results in their own format. Therefore we make sure that the `AllTests.js` file does not contain any UI output and just calls the various test cases of the app.

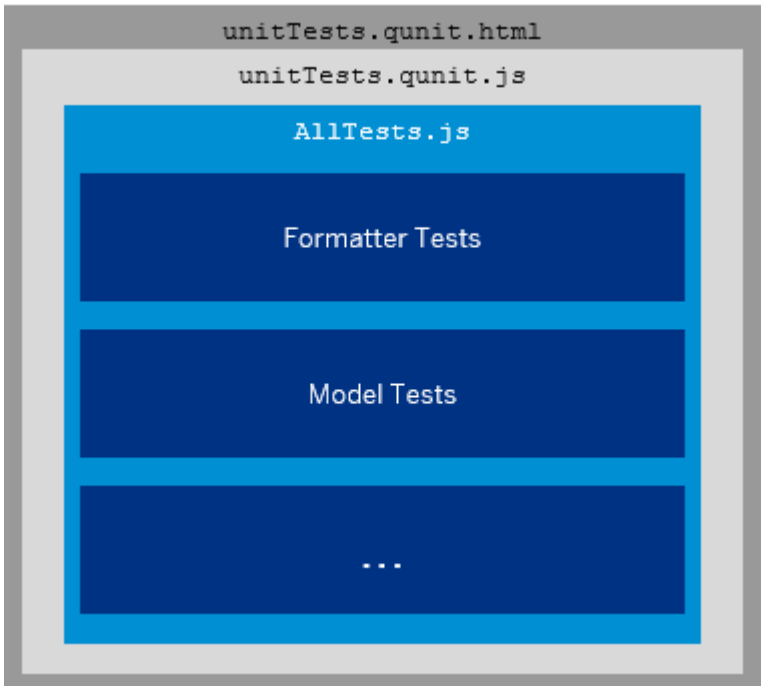

Figure 112: Unit test infrastructure in the application

Let's take a closer look at the `unitTests.qunit.html` file. The application root is stored in the `webapp` folder two levels above. In the `bootstrap` tag of the HTML page we define two namespaces to refer to the app and the unit tests. The namespace of the unit tests points to the current folder as all test artifacts are located below the current folder:

- `sap.ui.demo.bulletinboard: "../../"`
- `test.unit: "./"`

The namespace abstraction allows us to refer to all application and testing parts without having to use the full path. Furthermore, all unit tests are put in a similar folder structure and get the same name as the artifact that is tested. For example, the tests for the file `webapp/model/formatter.js` are located in the `webapp/test/unit/model/formatters.js` folder. For more details on the unit test setup please have a look at the coding of the prototype.

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing Apps - Step 2.

webapp/model/formatter.js

```
sap.ui.define([
    "sap/m/Text"
], function (Text) {
    "use strict";
    return {
```

```
        numberUnit: function (sValue) {
            …
        },
        priceState: function () {
        }
    };
});
```

First we think about the feature that we want to implement. We want to introduce a new state for the price, and its value should depend on certain price ranges. SAPUI5 controls typically have semantic states like *Success*, *Warning*, or *Error*. We will need this formatter function to convert the numeric price value from the model to a state value for the control. But without caring too much about the actual implementation of this formatter we just add an empty function `priceState` to the formatter file for now and focus on the unit tests first.

webapp/test/unit/model/formatter.js

```
sap.ui.define([
    "./model/formatter"
], function (formatter) {
    "use strict";
    QUnit.module("Number unit");
        …
    QUnit.module("Price State");

    function priceStateTestCase(oOptions) {
        // Act
        var sState = formatter.priceState(oOptions.price);

        // Assert
        oOptions.assert.strictEqual(sState, oOptions.expected, "The price state
was correct");
    }

    QUnit.test("Should format the products with a price lower than 50 to
Success", function (assert) {
        priceStateTestCase.call(this, {
            assert: assert,
            price: 42,
            expected: "Success"
        });
    });

    QUnit.test("Should format the products with a price of 50 to Normal",
function (assert) {
        priceStateTestCase.call(this, {
            assert: assert,
            price: 50,
            expected: "None"
        });
    });

    QUnit.test("Should format the products with a price between 50 and 250 to
Normal", function (assert) {
        priceStateTestCase.call(this, {
            assert: assert,
            price: 112,
            expected: "None"
        });
    });

    QUnit.test("Should format the products with a price between 250 and 2000 to
```

```
Warning", function (assert) {
        priceStateTestCase.call(this, {
            assert: assert,
            price: 798,
            expected: "Warning"
        });
    });

    QUnit.test("Should format the products with a price higher than 2000 to
Error", function (assert) {
        priceStateTestCase.call(this, {
            assert: assert,
            price: 2001,
            expected: "Error"
        });
    });
});
```

Now we write tests that call the function we have just defined and check for the correct result when passing in various arguments.

By writing these tests, we actually implement the following specification in our tests that was defined by the product team.

- price < 50: Status is green (*Success*)
- price >= 50 and price < 250: Status is normal (*None*)
- price >= 250 and price < 2000: Status is orange (*Warning*)
- price >= 2000: Status is red (*Error*)

Whenever we run the tests, we will implicitly check that the feature is still working as it was designed. To keep it simple, we should only write a minimum set of tests that cover the most important cases, but also including edge cases like the value 50 or unexpected values.

Let's have a look at the implementation of the unit tests now: We add our unit tests to the `webapp/test/unit/model/formatter.js` file. The path below the app and the test folder is similar so it can easily associate the test with the tested functionality. There are already formatter functions for the number unit conversion defined in the code - you can have a quick look before we add our own tests.

We add a new QUnit module for our price state tests after the number unit conversion tests. We could write a test checking the result of the formatter for each of these cases but we do not want to repeat ourselves ("DRY") – neither in the tests nor in the application coding – so we create a reuse function called `priceStateTestCase`. In this function, we call the formatter with the arguments provided as `oOptions` and make a `strictEqual` assertion for the expected parameter.

> **i** Note
>
> There must be at least one assertion per QUnit test. If the actual value matches the expected value then the test is successful. However, if there are more assertions in a test case and a subsequent assertion fails, the whole test fails with the error message of the failed assertion.
>
> There are also other types of assertions, for example the `ok` assertion that does not check the type. For more details, have a look at the official QUnit documentation.

The assert object – a special object injected by QUnit – is passed on as a reference to the function. QUnit is loaded once for the whole unit testing part of the app.

> **i Note**
>
> The main page for calling the unit tests is `webapp/test/unit/unitTests.qunit.html`. In this file we load the QUnit runtime and an `AllTests.js` file that loads and directly executes all files with unit tests. The other content of this file is just HTML for displaying the QUnit test result page.

And now for the actual test cases: Whenever we want to start a new test we call `QUnit.test` with a test description and a callback function containing the test logic as an argument. The callback is invoked with a special assert object that is maintained by QUnit. We can simply call assertions as we saw above.

Inside each test we simply call our reuse function with different parameters for the price and the expected state that reflect our specification above. With five tests we can check the most important cases for our price state converter. There are four tests for the four different states and one edge case test with the value `50`, that makes sure that the correct state is chosen.

That's it, you just wrote your first unit test. When you call the `webapp/test/unit/unitTests.qunit.html` file in your browser, you can see that the first module for the number unit formatter is still green but our price state tests are red and failing. The error message tells us that the result of the empty formatter function is not as expected.

TDD methodology tells us to do the implementation as soon as the test fails and to come back to testing as soon as the tests are successful again. You run the unit tests after each code change, and you're done when the test does not fail anymore. We now switch to the implementation part and define the details of the formatter function in the next step.

Conventions

- Write unit tests for testing the logical correctness of your features

Unit Testing with QUnit [page 1159]
QUnit Home Page

Step 3: Adding the Price Formatter

We will now take care of the implementation of the price formatter and make sure that the tests we wrote in the previous step run successfully.

If the tests are passed, we can be sure that the formatter is formally correct but it is still not visible in the app. So additionally, we will add the formatter to the UI to be able to verify and check that the price is shown properly.

Preview

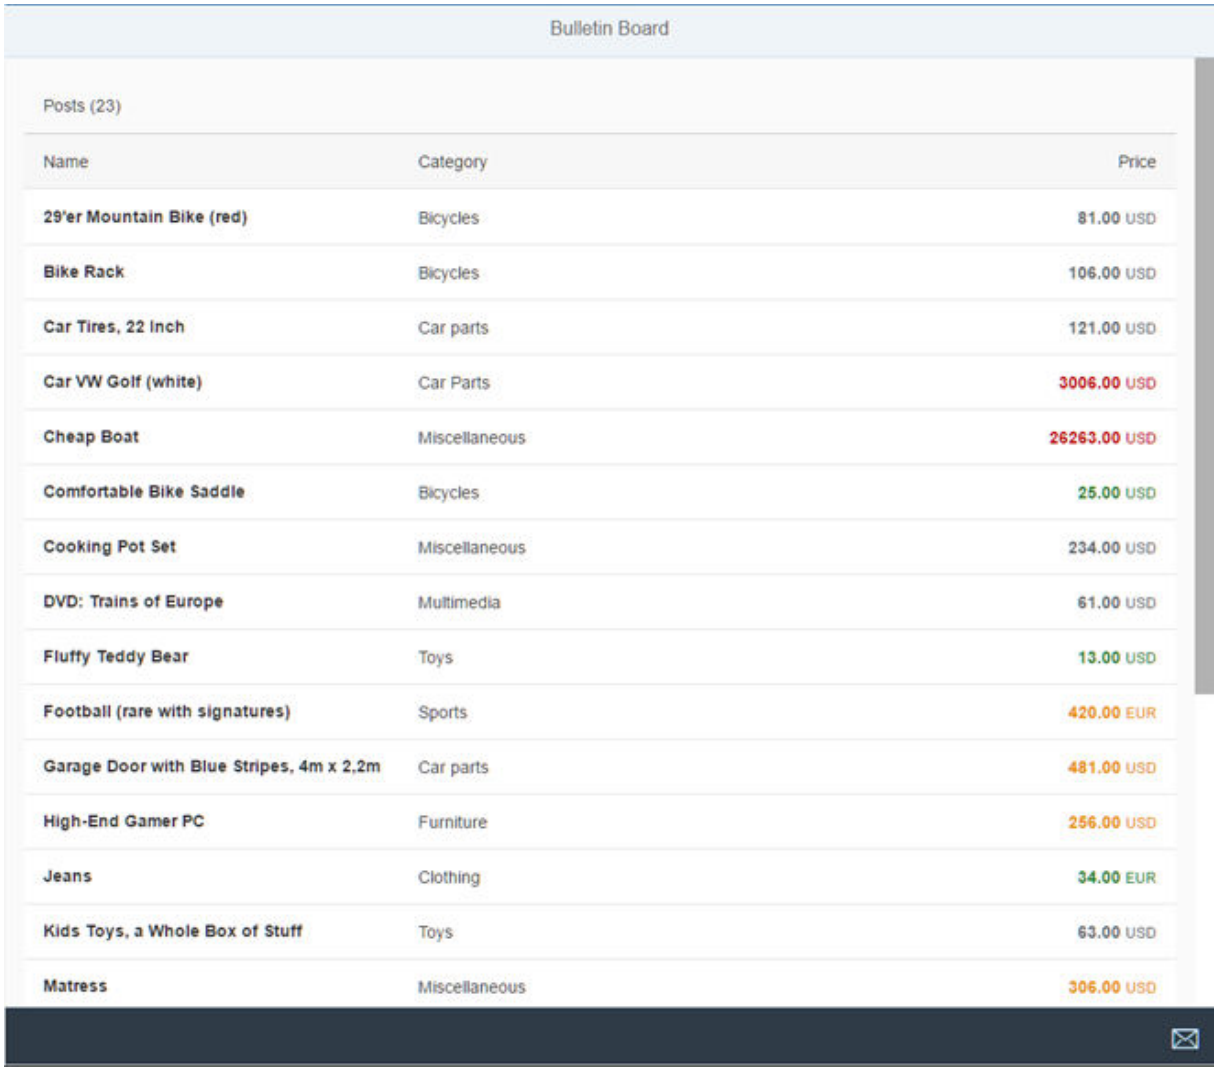

Figure 113: The price is now formatted with a semantic color

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 3.

webapp/model/formatter.js

```
sap.ui.define([
    "sap/m/Text"
], function (Text) {
    "use strict";
    return {
        numberUnit: function (sValue) {
            …
```

```
        },
        /**
         * Defines a value state based on the price
         *
         * @public
         * @param {number} iPrice the price of a post
         * @returns {string} sValue the state for the price
         */
        priceState: function (iPrice) {
            if (iPrice < 50) {
                return "Success";
            } else if (iPrice >= 50 && iPrice < 250) {
                return "None";
            } else if (iPrice >= 250 && iPrice < 2000) {
                return "Warning";
            } else {
                return "Error";
            }
        }
    };
});
```

We change the empty formatter function that we have added in the last step and add the implementation details to it. If the implementation matches the specification embedded in our tests we are done with implementing the formatter.

The input for the formatter is the price value from the model and the result is the state as a `string` value. The actual implementation logic is quite simple and returns a semantic state value based on the price as we have seen already in the test. There are four cases that are reflected in the `if/else` statements inside the formatter.

You can now run the file `webapp/test/unit/unitTests.qunit.html` and check if the unit tests run successfully. You should see your new test cases on the result page. If the overall result is successful then we have successfully implemented our first feature.

webapp/view/Worklist.view.xml

```
…
<ColumnListItem vAlign="Middle">
    <cells>
        …
        <ObjectNumber
            number="{
                path: 'Price',
                formatter: '.formatter.numberUnit'
            }"
            state="{
                path: 'Price',
                formatter: '.formatter.priceState'
            }"
            unit="{Currency}"/>
    </cells>
</ColumnListItem>
…
```

We still have to apply the changes to our UI so that we can actually see the formatted price in the app. Unit tests are typically testing the logic independent of the user interface. That is why the tests are running successfully even though we did not adapt the UI yet.

In our worklist view we simply add a state attribute to the `ObjectNumber` control in the `columns` aggregation. We define the same data binding path as for the number, but we use our new formatter function to determine the proper state. If you now run the `webapp/test/mockServer.html` file, you can see that some of the product prices are listed in green, black, orange, and red depending on their price.

Related Information

API Reference: `sap.ui.core.ValueState`
API Reference: `sap.m.ObjectNumber`

Step 4: Testing a New Module

In the first unit test we have just extended the formatters module with a new function. Now we will write a unit test that will test the functionality of an entirely new module.

A frequently used feature of a bulletin board is to flag interesting posts to mark them for later reading. The UI should contain a button to toggle the flagged state for each item. We will implement this feature with a custom type and again start writing the test case for it first and add the implementation later.

Preview

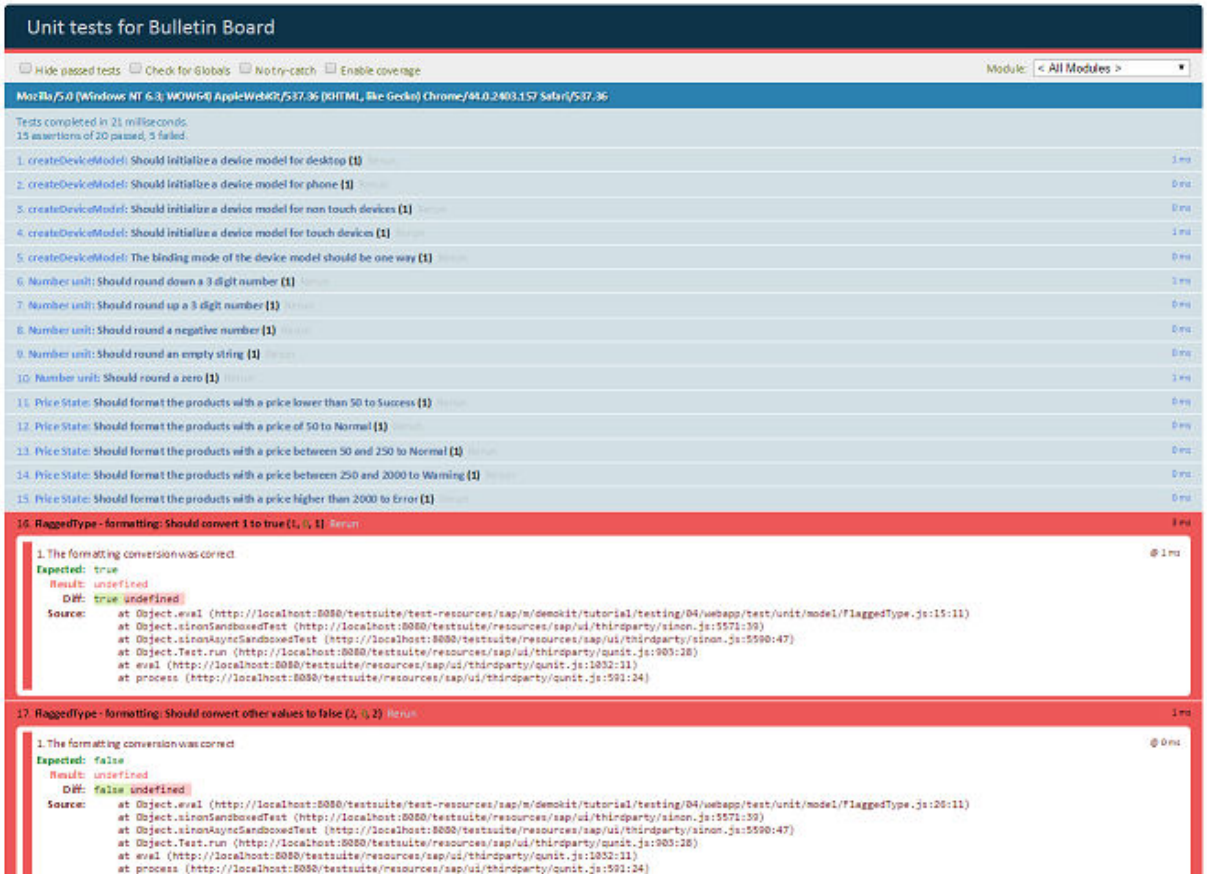

Figure 114: The unit test for the `Flagged` feature will fail until the feature is implemented

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 4.

webapp/model/FlaggedType.js (new)

```
sap.ui.define([
    "sap/ui/model/SimpleType"
], function (SimpleType) {
    "use strict";
    return SimpleType.extend("sap.ui.demo.bulletinboard.model.FlaggedType", {
        formatValue: function () {
        },
        parseValue: function () {
        },
        validateValue: function () {
        }
    });
});
```

We plan to control a button state based on the `Flagged` property in the model. The button expects a Boolean value for the pressed state. In the model, we have a binary integer representation, so we will again need conversion logic to format the model value. And we also need a back conversion to store a state change in the model when the user clicks the button.

A formatter function will only take care of one direction so this time we decide to implement a custom data type for the conversions. As with the previous test, we add an empty hull for our new data type in the model folder. The `FlaggedType` extends the `SimpleType`. Its interface provides two conversion functions and a validation function:

- `formatValue`: formats a model value to be displayed in the UI
- `parseValue`: parses a UI value to be stored in the model
- `validateValue`: checks a value for displaying validation errors

webapp/test/unit/model/FlaggedType.js (new)

```
sap.ui.require(
    [
        "sap/ui/demo/bulletinboard/model/FlaggedType"
    ],
    function (FlaggedType) {
        "use strict";
        QUnit.module("FlaggedType - formatting");
        QUnit.test("Should convert 1 to true", function (assert) {
            // Act
            var bFormattedValue = new FlaggedType().formatValue(1);
            // Assert
            assert.strictEqual(bFormattedValue , true, "The formatting
conversion was correct");
        });
        QUnit.test("Should convert other values to false", function (assert) {
            var oFlaggedType = new FlaggedType();
            // Act
            var bFormattedZero = oFlaggedType.formatValue(0);
            var bFormattedNegativeNumber = oFlaggedType.formatValue(-666);
            // Assert
            assert.strictEqual(bFormattedZero, false, "The formatting conversion
was correct");
            assert.strictEqual(bFormattedNegativeNumber, false, "The formatting
conversion was correct");
        });
        QUnit.module("FlaggedType - parsing");
        QUnit.test("Should parse false to 0", function (assert) {
            // Act
            var iParsedValue = new FlaggedType().parseValue(false);
            // Assert
            assert.strictEqual(iParsedValue, 0, "The parsing conversion matched
the input");
        });
        QUnit.test("Should parse true to 1", function (assert) {
            // Act
            var iParsedValue = new FlaggedType().parseValue(true);
            // Assert
            assert.strictEqual(iParsedValue, 1, "The parsing conversion matched
the input");
        });
    }
);
```

The new `FlaggedType.js` file matches the file name of the implementation and is put in the `model` subfolder of the `test/unit` folder similar to the implementation under the `webapp` folder. By keeping the same structure for tests and productive code, we can easily relate the tests to the implementation.

We define this testing module with `sap.ui.require` since we just want to load dependencies but do not want to declare a namespace for this testing module. We load the new and still empty `FlaggedType` implementation as the only dependency and declare two QUnit modules: one for formatting and one for parsing, to check both the to- and back-conversion of the flagged type.

> **i Note**
>
> We do not test the validation function of the data type as our conversion is so simple. There are no expected validation errors that we have to take care of.

In each QUnit module we define test cases for each condition. For a Boolean conversion there are just two cases, `true` and `false`. So we expect that the integer value `1` is converted to `true` and everything else to `false`.

Let's have a look at the first test case to see how the custom data type is invoked for testing.

As we have loaded the type as a dependency, we can just access it with the variable `FlaggedType` and create a new instance of it in each test case. This time we do not create a `reuse` function but simply create the instance inside the test case. On the type we manually call the function `formatValue` that we want to test and compare the result to the expected value in an assertion.

In the second test case, we check all other values, we expect it to be `0` but it could be also a negative value. So we check both cases in the same test case with a separate assertion each. Only when both assertions are fulfilled the test will be successful.

The other test cases in the parsing module are similar and check the back conversion from Boolean value to integer value.

webapp/test/unit/AllTests.js

```
sap.ui.define([
    "./model/models",
    "./model/formatter",
    "./model/FlaggedType"
], function() {
    "use strict";
});
```

In the `AllTests.js` file we just load the new testing module as a dependency so that it is executed automatically whenever we execute the unit tests.

You can now call the unit tests and check the result. As in the previous step, the tests should fail with an error message that the conversion is not correct. This is expected as we did not implement the conversion logic yet but just the tests for it.

Conventions

- Use data types if you need both formatting and parsing of a model value
- Organize the tests in the same file structure as the productive code

API Reference: `sap.ui.model.SimpleType`

API Reference: `sap.ui.require`

Formatting, Parsing, and Validating Data [page 854]

Step 5: Adding a *Flag* Button

Now that we have implemented the conversion tests, we add the corresponding functionality and show the button to flag a post in the app. The design team has specified that the flag feature should be implemented with a toggle button that has a flag icon.

Preview

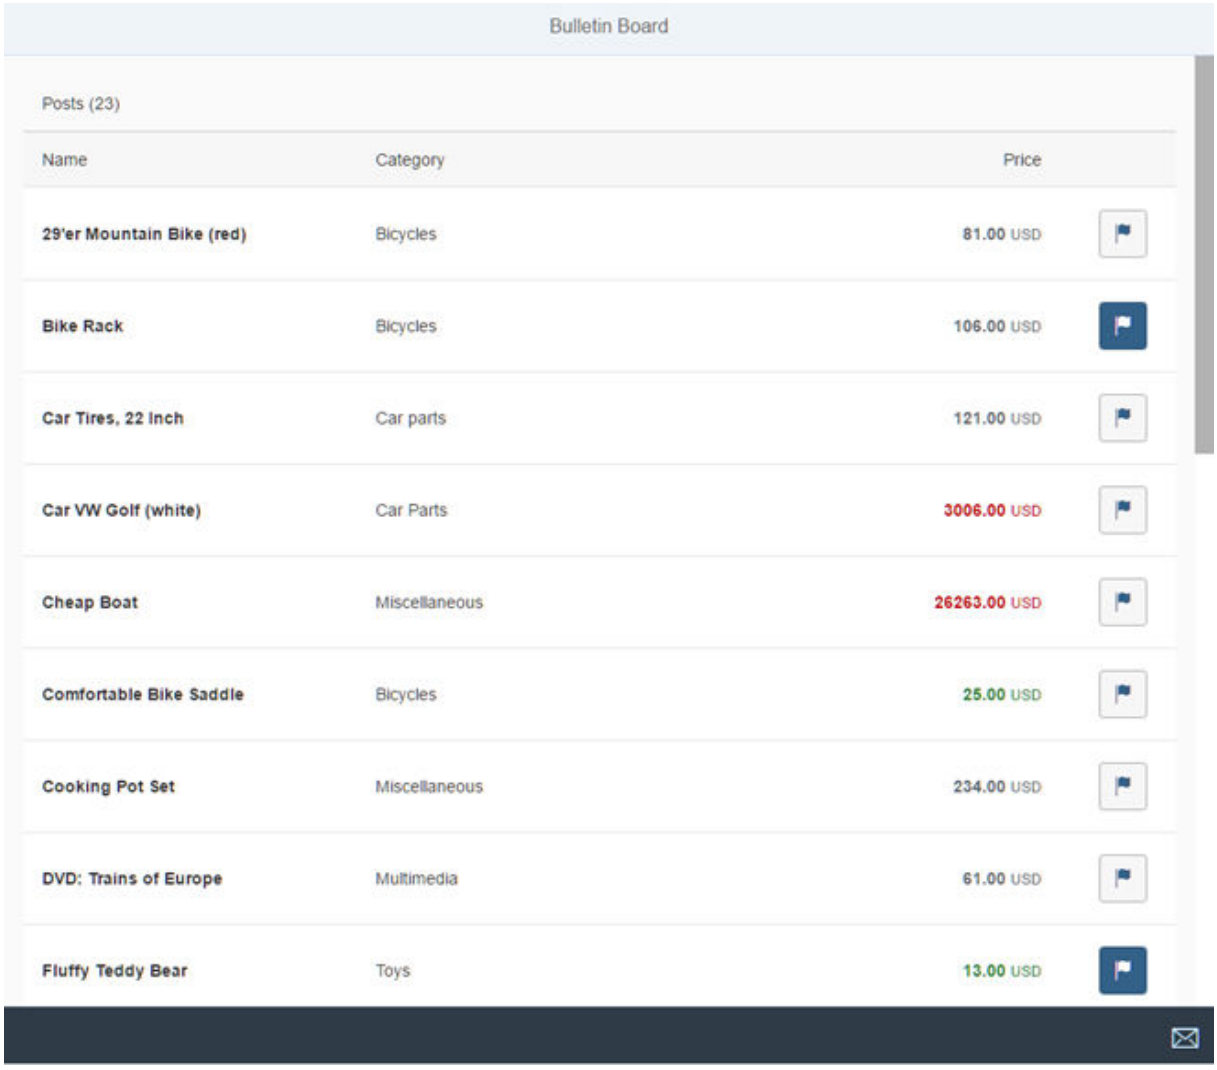

Figure 115: The *Flag* button is now added to the table

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 5.

webapp/model/FlaggedType.js

```
sap.ui.define([
    "sap/ui/model/SimpleType"
], function (SimpleType) {
    "use strict";
    return SimpleType.extend("sap.ui.demo.bulletinboard.model.FlaggedType", {
        /**
         * Formats the integer value from the model to a boolean for the pressed
state of the flagged button
         *
         * @public
         * @param {number} iFlagged the integer value of the formatted property
         * @returns {boolean} 1 means true, all other numbers means false
         */
        formatValue: function (iFlagged) {
            return iFlagged === 1;
        },
        /**
         * Parses a boolean value from the property to an integer
         *
         * @public
         * @param {boolean} bFlagged true means flagged, false means not flagged
         * @returns {number} true means 1 , false means 0
         */
        parseValue: function (bFlagged) {
            if (bFlagged) {
                return 1;
            }

            return 0;
        },
        /**
         * Validates the value to be parsed
         *
         * @public
         * Since there is only true and false, no client side validation is
required
         * @returns {boolean} true
         */
        validateValue: function () {
            return true;
        }
    });
});
```

Lets start with the implementation code for the `FlaggedType`. We now add the documentation in JSDoc format and the implementation of the three functions of the data type to the previously empty stub:

- The `formatValue` function takes care of the conversion from the model to the UI. As specified in the tests, a model value of `1` will be converted to `true`, everything else to `false`. In the implementation code, this equals to `"iFlagged === 1"`.
- Similarly, the `parseValue` function is called by SAPUI5 when the data is written back to the model. Here, we convert the Boolean value to an integer again.
- The validation function always returns `true` in this simple case, we do not expect any validation errors for this data type.

We call these functions of the data type in the unit tests directly. So if you now run your unit tests by calling the `webapp/test/unit/unitTests.qunit.html` page, the tests should already run successfully.

webapp/view/Worklist.view.xml

```
…
<Table …>
    …
    <columns>
        …
        <Column width="33%" id="unitNumberColumn" hAlign="End" vAlign="Middle">
            <Text text="{i18n>TableUnitNumberColumnTitle}"
id="unitNumberColumnTitle"/>
        </Column>
        <Column width="80px" id="flaggedColumn" demandPopin="true"
vAlign="Middle"/>
    </columns>
    <items>
        <ColumnListItem vAlign="Middle">
            <cells>
                …
                <ObjectNumber… />
                <ToggleButton
                    id="flaggedButton"
                    tooltip="{i18n>flaggedTooltip}"
                    icon="sap-icon://flag"
                    pressed="{
                        path: 'Flagged',
                        type: '.types.flagged'
                    }"
                    class="sapUiMediumMarginBeginEnd"/>
            </cells>
        </ColumnListItem>
    </items>
</Table>
…
```

In the view, we add a new column and a cell for the flag feature at the end of the table. We fill the cell with a `sap.m.ToggleButton` control that serves as our input control for the `Flagged` state. We define a `flag` icon in the button, a tooltip from the resource bundle, and a layouting class to make our example complete. The control's `pressed` property is bound to the `Flagged` field in the model. Here we also apply the custom data type that is part of the controller.

webapp/controller/Worklist.controller.js

```
sap.ui.define([
    './BaseController',
    'sap/ui/model/json/JSONModel',
    '../model/formatter',
    '../model/FlaggedType'
    'sap/m/library'
], function (BaseController, JSONModel, formatter, FlaggedType, mobileLibrary) {
    "use strict";
    return
BaseController.extend("sap.ui.demo.bulletinboard.controller.Worklist", {
        types : {
            flagged: new FlaggedType()
        },
        formatter: formatter,
        …
    });
});
```

The controller loads the custom data type as a dependency similar to the formatters. It is then provided as a property of the internal variable `types` so that it can be accessed as `.types.flagged` in the view as we have seen above.

The conversion functions that are made available when we create an instance of the type are called automatically by SAPUI5 when needed. However, by default the back conversion to the model is not enabled, so we still need a small change in the component.

webapp/Component.js

```
sap.ui.define([
    …
], function (UIComponent, ResourceModel, models) {
    "use strict";
    return UIComponent.extend("sap.ui.demo.bulletinboard.Component", {
    …
        init: function () {
            // call the base component's init function
            UIComponent.prototype.init.apply(this, arguments);
            // allow saving values to the OData model
            this.getModel().setDefaultBindingMode("TwoWay");
            …
        }
    });
});
```

To enable the propagation of the bound view properties to the model, we need to set the model's default binding mode to `TwoWay`. For an OData model the default mode is `OneWay` which means that properties are not written back to the model automatically. We want to propagate the state of the button automatically to the model, when the button for a post is clicked.

webapp/i18n/i18n.properties

```
#~~~ Worklist View ~~~~~~~~~~~~~~~~~~~~~~~~~
…
#XTOL: tooltip for the flagged button
flaggedTooltip=Mark this post as flagged
…
```

Finally, add the new string for the button tooltip to the resource bundle file. Now we can also test the application manually by calling the `webapp/test/mockServer.html` page and making sure some of the buttons are pressed initially as reflected in the model. When we flag an item by choosing the button, the property is written back to the model transparently.

> **i** Note
>
> As this feature covers both conversion and interaction parts, we could also have written an integration test for it to test the interaction part also. Feel free to add an integration test for this feature if you like, we will skip it here to focus on unit testing in this step.

Formatting, Parsing, and Validating Data [page 854]

Step 6: A First OPA Test

A bulletin board may contain many posts. We expect to have a high data load once it is officially released. Then, there might be performance issues and long loading times if we display all entries at the same time. Therefore we will introduce a feature that limits the initial display to 20 items. The user can then click on a more button to view more items. As with the unit test, we start by writing an integration test for this feature and then add the application functionality later.

Preview

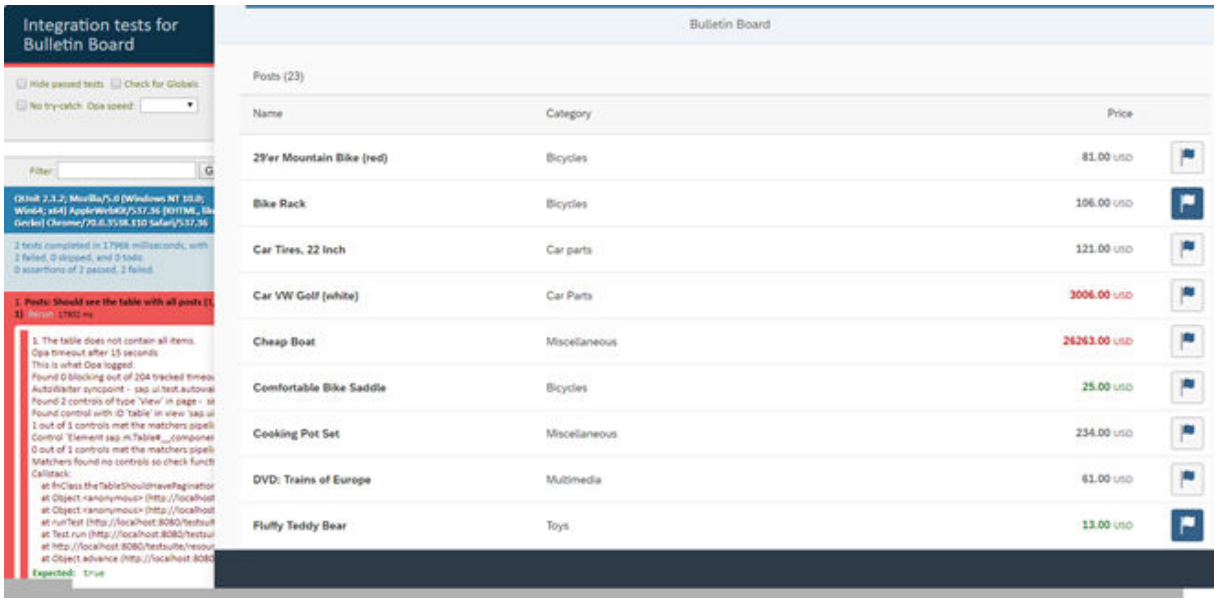

Figure 116: The OPA test page is waiting for more items to be loaded

Coding

You can view and download all files in the Demo Kit at Testing - Step 6.

Integration Test Setup

All integration tests are located in the `webapp/test/integration` folder and can be started manually by calling the `opaTests.qunit.html` file in the same folder or the entry page. Similar to the unit tests, the HTML

page is a QUnit runner that calls all integration tests of the app and displays the test results in a readable format. It also might be omitted by other testrunners. There are also two namespaces defined for the app and the integration test folder as you have seen in the unit test setup.

We write integration tests with OPA5 – a tool that is integrated and delivered with SAPUI5. It is the short name for One-Page Acceptance tests for SAPUI5. "One-Page" here means that OPA5 is designed for single-page Web applications, i.e. applications that consist only of one HTML file. OPA5 runs in the same browser window as the application to be tested.

> **i Note**
>
> There is also a stand-alone version of OPA5 called “OPA” available that can be used for testing any kind of single-page Web application and that does not provide any SAPUI5-specific functionality. In this tutorial, “OPA” always refers to OPA5. It includes functionality for easily finding and matching SAPUI5 controls as well as their properties and aggregations.

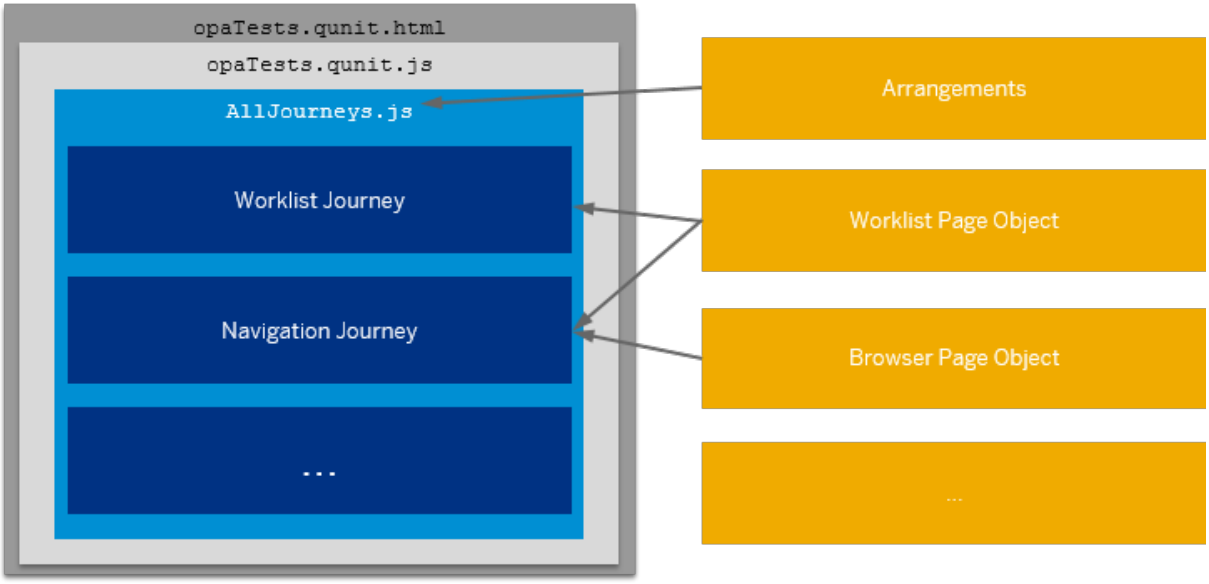

Figure 117: Integration test infrastructure in the project

For structuring integration tests with OPA we use “journeys”. A test journey contains all test cases for a specific view or use case, for example the navigation journey simulates user interaction with the app.

The journey uses another structuring element of OPA called “page object” that encapsulates actions and assertions needed to describe the journey. Typically those are related to a view in the app but there can also be stand-alone pages for browsers or common functionality.

> **i Note**
>
> When you first start writing tests, you may find it difficult to figure out the correct control locators. The *Test Recorder* tool can suggest a solution in the form of a code snippet. For most controls, it can find a combination of matchers that match a single control. Then, all you need to do is copy the code snippet to your OPA5 page object. For more information, see Test Recorder [page 1251].

webapp/test/integration/WorklistJourney.js

```
sap.ui.define([
    "sap/ui/test/opaQunit",
    "./pages/Worklist"
], function (opaTest) {
    "use strict";
    QUnit.module("Posts");
    opaTest("Should see the table with all posts", function (Given, When, Then) {
        // Arrangements
        Given.iStartMyApp();
        // Assertions
        Then.onTheWorklistPage.theTableShouldHavePagination().
            and.theTitleShouldDisplayTheTotalAmountOfItems();
    });

    opaTest("Should be able to load more items", function (Given, When, Then) {
        //Actions
        When.onTheWorklistPage.iPressOnMoreData();

        // Assertions
        Then.onTheWorklistPage.theTableShouldHaveAllEntries();
        // Cleanup
        Then.iTeardownMyApp();
    });
});
```

Let's add our first new OPA test to the `WorklistJourney.js` file. We describe all test cases related to the worklist logic. We can see that there is already a test `Should see the table with all posts` defined that checks if the table contains the expected number of items. There is a function `opaTest` that initiates a test description and receives a test description as the first argument as well as a callback function as the second argument. This format is similar to the unit test function `QUnit.test` except for the three arguments of the callback function that are specific to OPA.

The three objects `Given`, `When`, `Then` are filled by the OPA runtime when the test is executed and contain the `arrangements`, `actions`, and `assertions` for the test. The "Given-When-Then" pattern is a common style for writing tests in a readable format. To describe a test case, you basically write a user story. Test cases in this format are easy to understand, even by non-technical people.

Let's give it a try with our new feature that only displays 20 posts in the table initially and will load more posts when we press a trigger button or scroll down. Here is our user story "Should see the table with all posts" and its code representation:

- **Arrangements**
  Define possible initial states, e.g. the app is started, or specific data exists. For performance reasons, starting the app is usually done only in the first test case of a journey. `Given.iStartMyApp();`
- **Actions**
  Define possible events triggered by a user, e.g. entering some text, clicking a button, navigating to another page. `When.onTheWorklistPage.iPressOnMoreData();`
- **Assertions**
  Define possible verifications, e.g. do we have the correct amount of items displayed, does a label display the right data, is a list filled. At the end of the test case, the app is destroyed again. This is typically done only once in the last test case of the journey for performance reasons.
  `Then.onTheWorklistPage.theTableShouldHaveAllEntries ().and.iTeardownMyApp();`

Please also note that you have to move the `and.iTeardownMyApp()` concatenation from the previous `opaTest` function and put it at the end of the last test of a journey, in this case this is our new test. For

performance reasons, we only start and destroy the app once per journey, as it takes several seconds to load the app. You can concatenate actions and assertions with the OPA helper object and in an easily readable way. The functions will be executed one after another.

Now you might wonder where all those descriptive functions and the helper object `onTheWorklistPage` are coming from. The answer is simple, the `onTheWorklistPage` object is a structuring element of OPA and inside we will implement the actions and assertions used in this test.

webapp/test/integration/pages/Worklist.js

```
sap.ui.define([
        'sap/ui/test/Opa5',
        'sap/ui/test/matchers/AggregationLengthEquals',
        'sap/ui/test/matchers/I18NText',
        'sap/ui/test/actions/Press'
    ],
        function (Opa5,
              AggregationLengthEquals,
              I18NText,
              Press) {
        "use strict";
        var sViewName = "Worklist",
            sTableId = "table";
        Opa5.createPageObjects({
            onTheWorklistPage: {
                actions: {
                    iPressOnMoreData: function () {
                        // Press action hits the "more" trigger on a table
                        return this.waitFor({
                            id: sTableId,
                            viewName: sViewName,
                            actions: new Press(),
                            errorMessage: "The table does not have a trigger."
                        });
                    }
                },
                assertions: {
                    theTableShouldHavePagination: function () {
                        return this.waitFor({
                            id: sTableId,
                            viewName: sViewName,
                            matchers: new AggregationLengthEquals({
                                name: "items",
                                length: 20
                            }),
                            success: function () {
                                Opa5.assert.ok(true, "The table has 20 items on
the first page");
                            },
                            errorMessage: "The table does not contain all items."
                        });
                    },
                    theTableShouldHaveAllEntries: function () {
                        return this.waitFor({
                            id: sTableId,
                            viewName: sViewName,
                            matchers: new AggregationLengthEquals({
                                name: "items",
                                length: 23
                            }),
                            success: function () {
```

```
                                Opa5.assert.ok(true, "The table has 23 items");
                            },
                            errorMessage: "The table does not contain all items."
                        });
                    },
                    theTitleShouldDisplayTheTotalAmountOfItems: function () {
                        return this.waitFor({
                            id: "tableHeader",
                            viewName: sViewName,
                            matchers: new I18NText({
                                key: "worklistTableTitleCount",
                                propertyName: "text",
                                parameters: [23]
                            }),
                            success: function () {
                                Opa5.assert.ok(true, "The table header has 23
items");
                            },
                            errorMessage: "The table header does not contain the
number of items: 23"
                        });
                    }
                }
            }
        });
```

As you can see, the OPA page object is constructed with the call `Opa5.createPageObjects` and a `configuration` object that contains the actions and assertions properties.

For our test case we need to add an action `iPressOnMoreData` and an existing assertion `theTableShouldHaveAllEntries`. OPA tests are running asynchronously, so each action and assertion starts with a `waitFor` statement. The OPA run time will check and wait for the condition to be fulfilled every 400 ms by polling. If the condition is met, the `success` function of the configuration is called. If the condition is still not fulfilled after a certain amount of time (by default it is 15 seconds but this can be configured) the test will fail.

Let's start with the action `iPressOnMoreData`. We define a `waitFor` statement with the current view and the table. Those IDs are stored as internal variables in the `require` statement above and are available in all tests. OPA will now try to find the table based on IDs. As soon as the table is available on the screen and it can be interacted with (it is visible, not busy,...), the `Press` action is invoked, if not, the error message is displayed and the test fails. When executed on a table, the `Press` action will simulate that a users chooses the *More Data* button.

> **i Note**
>
> The `Press` action depends on the control that it is triggered on and has a default behavior for most UI controls. If you, for example, execute `Press` on a `sap.m.Page`, this will trigger the *Back* button's `Press` event. This behavior can be overridden by passing an ID as argument to the action. For more information, see the API Reference: `sap.ui.test.actions.Press`.

The assertion `theTableShouldHaveAllEntries` is structured similarly, but it does not trigger an action. Here, we use the `success` function of `waitFor` to assert if our application is in the expected state. This state is defined by the matchers (in our case we expect that the list contains 23 items by using the `AggregationLengthEquals`. The `success` function does not execute the additional checks that are needed for triggering an action. the liste does not have to be `interactable` to verify that the state of the application is correct..

With this helper object we can simply check the length of the table aggregation `items` to the expected number of items. We have 23 entries in our local mock data that we also use for this integration test. You can see that the number of items is actually hard-coded in the test. So only if the table has exactly 23 items, the matcher is evaluating to `true` and the assertion is passed successfully.

> **i** Note
>
> The items in our app are served from the mock server with a slight delay so that we can see how a real service on a backend system would behave. Even if we would have a real backend, we would purposely use the mock server for manual testing and for using them in our test cases as the test data remains stable and unchanged. This creates a more reliable test environment and easier tests. So we can write a test that checks exactly for 23 items here.

Now run the `webapp/test/integration/opaTests.qunit.html` file and make sure that the test is failing. When our new test is invoked, OPA will run into a timeout because the trigger area is not found yet. You can see more information, if you open the developer console of your browser and check the messages in the console.

Conventions

- Use OPA tests for UI-related integration tests
- Structure OPA tests with page objects
- Use the standard matchers provided by OPA5 if possible

API Reference: `sap.ui.test.Opa5`
Samples: `sap.ui.test.Opa5`

Step 7: Changing the Table to a Growing Table

Let's switch back to developing and add the missing feature for the test we implemented in the previous step. We will simply change the table to a growing table as this is a basic feature of the table. This will display a trigger at the end of the table that the user can click on to display more items.

Preview

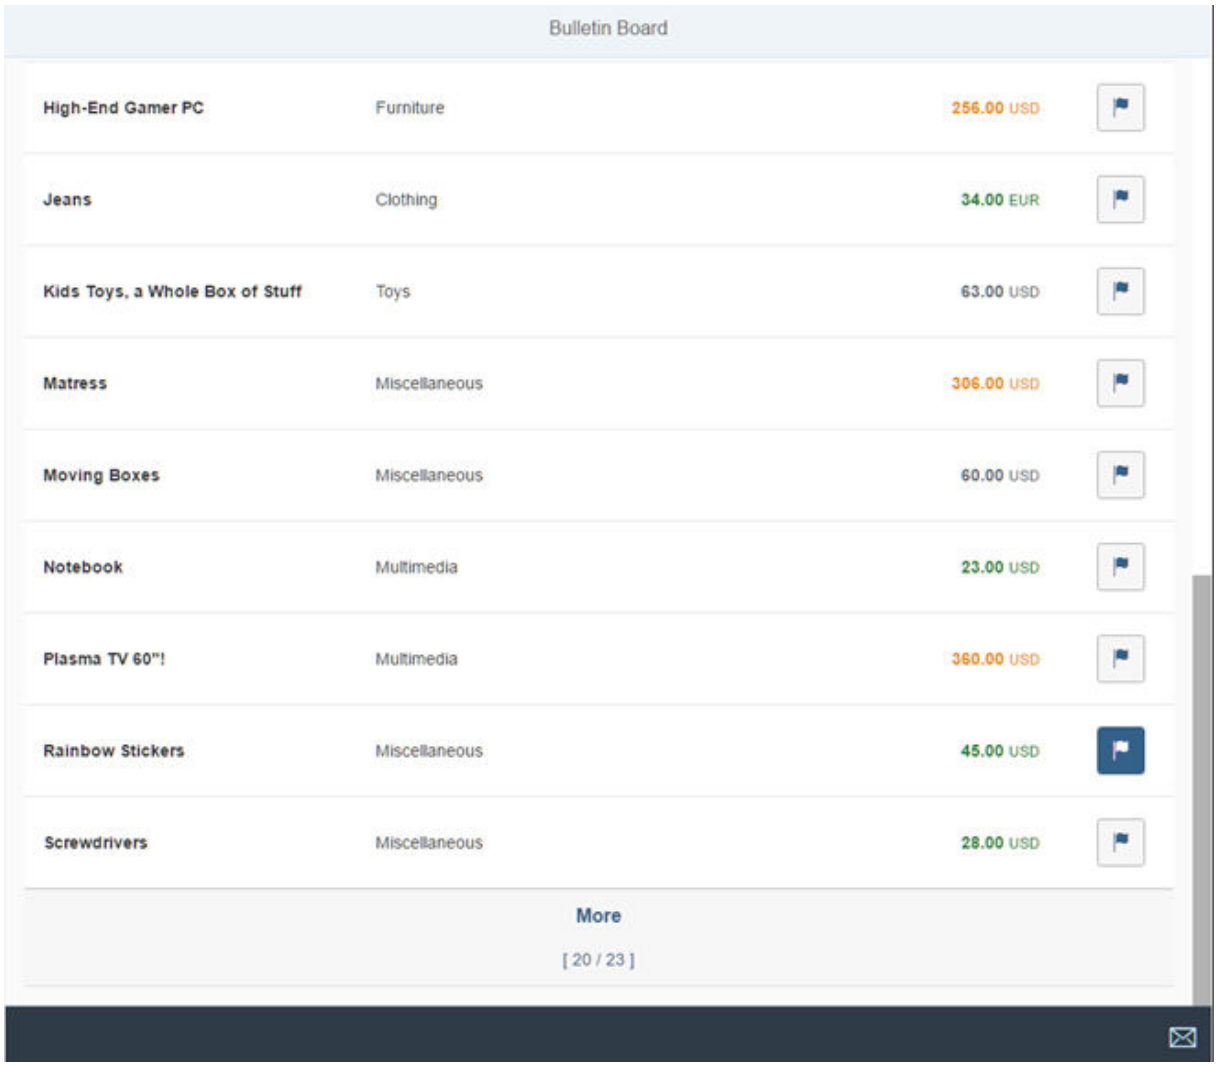

Figure 118: The List of posts is now dynamically loading more items when we scroll to the end of the page

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 7.

webapp/view/Worklist.view.xml

```
<mvc:View …
    <semantic:FullscreenPage
        id="page"
        title="{i18n>worklistViewTitle}">
        <semantic:content>
            <Table
                id="table"
                growing="true"
                width="auto"
                …
                >
            …
            </Table>
        </semantic:content>
        …
    </semantic:FullscreenPage>
</mvc:View>
```

We simply set the parameter `growing` to `true` to enable our feature. Now we can run the integration test that we just wrote in the previous step and it should not fail anymore. Similarly, if we run the app, we now see only 20 items initially. And if we choose the *More* button then three more items are loaded.

Conventions

- Use OPA tests for UI-related integration tests

Related Information

Growing Feature for Table and List [page 2342]
API Reference: `sap.m.Table`

Step 8: Testing Navigation

So far, we have a list of posts on the home page of the app. But typically, a post comes with more details that should be displayed on a separate detail page. We call it the post page because it displays details of a post. In this step we will introduce a new journey to test the post page. We write tests that trigger typical navigation events with OPA. Testing navigation greatly helps in reducing manual testing efforts as it covers a lot of testing paths. It is good practice to cover every view of your application with at least one test, since OPA will check if an exception is thrown. In this way you can detect critical errors very fast.

Preview

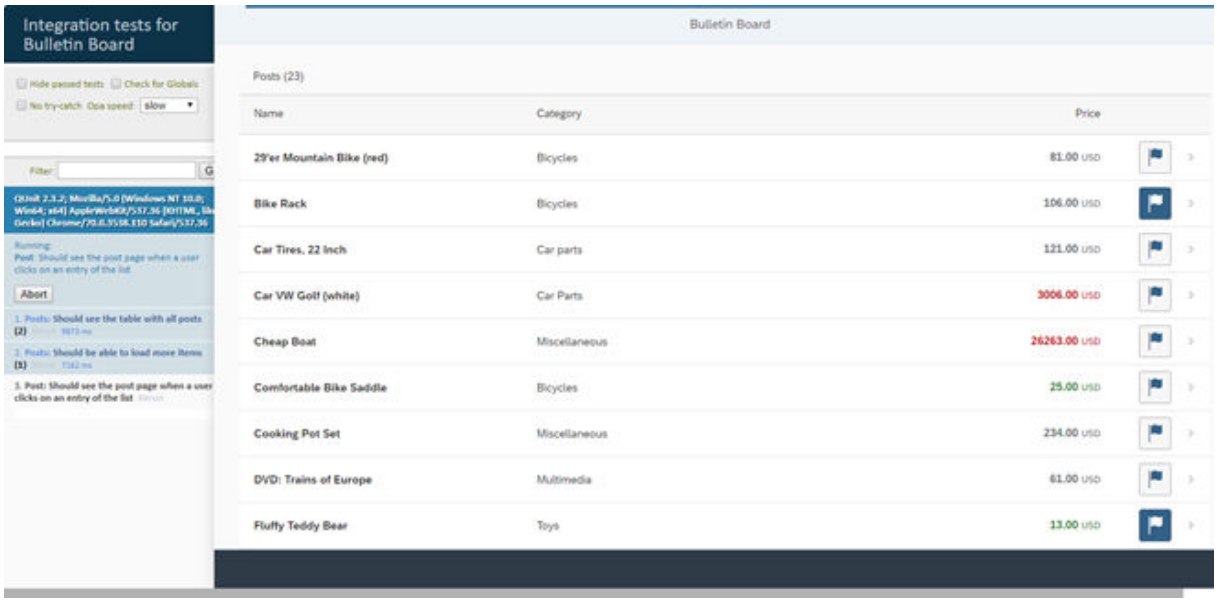

Figure 119: We add an OPA test that selects an item from the table and navigates to the post page

Coding

You can view and download all files in the Demo Kit at Testing - Step 8.

webapp/test/integration/PostJourney.js (New)

```
sap.ui.define([
    "sap/ui/test/opaQunit",
    "./pages/Worklist",
    "./pages/Browser",
    "./pages/Post"
], function (opaTest) {
    "use strict";

    QUnit.module("Post");

    opaTest("Should see the post page when a user clicks on an entry of the
list", function (Given, When, Then) {
        // Arrangements
        Given.iStartMyApp();

        //Actions
        When.onTheWorklistPage.iPressOnTheItemWithTheID("PostID_15");

        // Assertions
        Then.onThePostPage.theTitleShouldDisplayTheName("Jeans");
    });

    opaTest("Should go back to the TablePage", function (Given, When, Then) {
        // Actions
        When.onThePostPage.iPressTheBackButton();
```

```
        // Assertions
        Then.onTheWorklistPage.iShouldSeeTheTable();
    });

    opaTest("Should be on the post page again when the browser's forward button
is pressed", function (Given, When, Then) {
        // Actions
        When.onTheBrowser.iPressOnTheForwardButton();

        // Assertions
        Then.onThePostPage.theTitleShouldDisplayTheName("Jeans");

        // Cleanup
        Then.iTeardownMyApp();
    });
});
```

This new journey for the *Post* page introduces a test case that tests the navigation and also tests if the browser history is in the correct state, so that the user can navigate through our app with the back and forward button of the browser. This time, instead of adding a test we will add a new journey.

A journey represents a user's task in our app. Journeys start with the startup of our app and end with a teardown in the last test. We don't write isolated tests here, since starting up the app takes a lot of time and doing it too often slows down our test execution and feedback time considerably. If the execution speed of the tests is no problem, you may also write isolated tests.

Our new journey consists of three user interaction steps:

1. User chooses a *Post* to view the details
2. User chooses the *Back* button on the *Detail* page of the *Post* to see the list again
3. User chooses the *Forward* button to revisit the details of the post

webapp/test/integration/pages/Worklist.js – action object

```
sap.ui.define([
        'sap/ui/test/Opa5',
        'sap/ui/test/matchers/AggregationLengthEquals',
        'sap/ui/test/matchers/I18NText',
        'sap/ui/test/matchers/BindingPath',
        'sap/ui/test/actions/Press'
    ],
    function (Opa5,
              AggregationLengthEquals,
              I18NText,
              BindingPath,
              Press) {
        "use strict";
        var sViewName = "Worklist",
            sTableId = "table";
        Opa5.createPageObjects({
            onTheWorklistPage: {
                actions: {
…
                    ,
                iPressOnTheItemWithTheID: function (sId) {
                    return this.waitFor({
                        controlType: "sap.m.ColumnListItem",
                        viewName: sViewName,
                        matchers:  new BindingPath({
```

```
                                path: "/Posts('" + sId + "')"
                            }),
                            actions: new Press(),
                            errorMessage: "No list item with the id " + sId + "
was found."
                        });
                    }
```

Now that we have written our spec how the navigation to the *Post* page is planned, we first need to implement the "click" on a list item. To identify the item we are looking for, we use the `BindingPath` matcher. Doing so, we make sure that even if the order of the items changes, we always choose the same item. The `press` action simulates a user click on the item.

webapp/test/integration/pages/Post.js (New)

```
sap.ui.define([
    'sap/ui/test/Opa5',
    'sap/ui/test/matchers/Properties',
    'sap/ui/test/actions/Press'
], function (Opa5, Properties, Press) {
        "use strict";
        var sViewName = "Post";
        Opa5.createPageObjects({
            onThePostPage: {
                baseClass: Common,
                actions: {
                    iPressTheBackButton: function () {
                        return this.waitFor({
                            id: "page",
                            viewName: sViewName,
                            actions: new Press(),
                            errorMessage: "Did not find the nav button on object
page"
                        });
                    }
                },
                assertions: {
                    theTitleShouldDisplayTheName: function (sName) {
                        return this.waitFor({
                            success: function () {
                                return this.waitFor({
                                    id: "objectHeader",
                                    viewName: sViewName,
                                    matchers: new Properties({
                                        title: sName
                                    }),
                                    success: function (oPage) {
                                        Opa5.assert.ok(true, "was on the
remembered detail page");
                                    },
                                    errorMessage: "The Post " + sName + " is not
shown"
                                });
                            }
                        });
                    }
                }
            }
        });
    });
```

After navigating to the *Post* page, we need a new OPA5 `Page` object for the page to implement our actions and assertions.

An OPA5 `Page` object is used to group and reuse actions and assertions that are related to a specific part of the screen. For more information, see Cookbook for OPA5 [page 1188].

We implement a `press` event on the page's `nav` button and we assert that we are on the correct page by checking the title in the object header. The `nav` button is retrieved via DOM reference, because the page does not offer us an API here. Since the DOM ID is the most stable attribute, we are using this to retrieve the button.

webapp/test/integration/pages/Worklist.js – assertion object

```
…
,
                    iShouldSeeTheTable: function () {
                        return this.waitFor({
                            id: sTableId,
                            viewName: sViewName,
                            success: function () {
                                Opa5.assert.ok(true, "The table is visible");
                            },
                            errorMessage: "Was not able to see the table."
                        });
                    }
…
```

After going back, we want to move forwards again, but we need to check if the back navigation actually took place. So we assert that we are back on our table of posts again. We achieve this with a very simple `waitFor` statement just checking if the table is present.

webapp/test/integration/pages/Browser.js (New)

```
sap.ui.define([
    'sap/ui/test/Opa5'
], function (Opa5) {
    "use strict";
        Opa5.createPageObjects({
            onTheBrowser: {
                baseClass: Common,
                actions: {
                    iPressOnTheForwardButton: function () {
                        return this.waitFor({
                            success: function () {
                                Opa5.getWindow().history.forward();
                            }
                        });
                    }
                },
                assertions: {}
            }
        });
    });
```

We now implement an action that is triggered when the *Forward* button is chosen. Since it is not part of the browser's UI and it could be used on any page of our application, we just declare our browser's UI as an own

OPA page object. To simulate the *Forward* button, we use the `history` API of the browser. We have to wrap our action in a `waitFor` statement. Otherwise the action would be executed before our app is started.

webapp/test/integration/AllJourneys.js

```
sap.ui.define([
    "sap/ui/test/Opa5",
    "./arrangements/Startup",
    "./WorklistJourney",
    "./PostJourney"
], function (Opa5, Startup) {
    "use strict";
    Opa5.extendConfig({
        arrangements: new Startup(),
        viewNamespace: "sap.ui.demo.bulletinboard.view.",
        autoWait: true
    });
});
```

To make navigation tests complete, we add the new journey to the `AllJourneys` file that is invoked by the OPA test page.

If you execute the tests now, you can see in the logs of the developer tools that OPA is waiting for the object page to be displayed. Of course, this will not happen as it is not yet implemented. But we already have a pretty good idea on how we will implement the feature in the next step

Related Information

API Reference: `sap.ui.test.matchers.BindingPath`

Step 9: Adding the *Post* Page

Now that we have covered all kinds of tests for navigation, we introduce our *Post* page that shows details of a post in the bulletin board. To achieve this, we have to introduce a new view/controller pair and adjust the routing of the application.

Preview

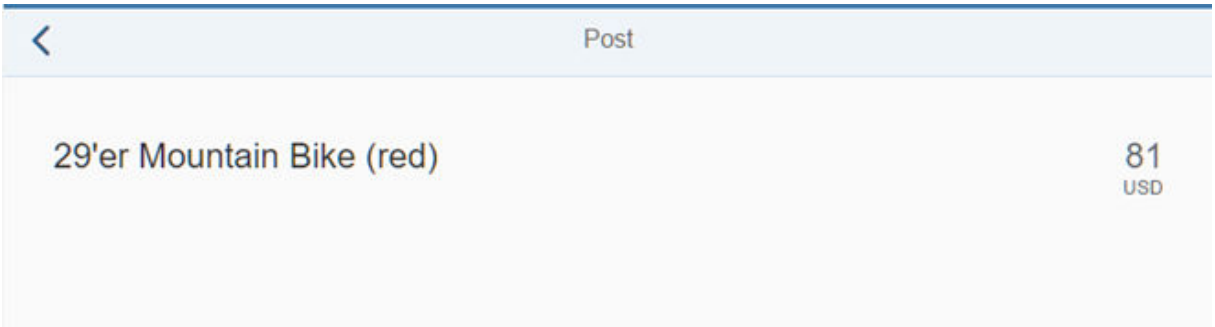

Figure 120: The *Post* page with more details about the post

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 9.

webapp/manifest.json

```
{
    "_version": "1.12.0",
    …
    "sap.ui5": {
    …
        "routing": {
            "config": {
                "routerClass": "sap.m.routing.Router",
                "viewType": "XML",
                "viewPath": "sap.ui.demo.bulletinboard.view",
                "controlId": "app",
                "controlAggregation": "pages",
                "async": true
            },
            "routes": [
                {
                    "pattern": "",
                    "name": "worklist",
                    "target": "worklist"
                },
                {
                    "pattern": "Post/{postId}",
                    "name": "post",
```

```
                    "target": "post"
                }
            ],
            "targets": {
                "worklist": {
                    "viewName": "Worklist",
                    "viewId": "worklist",
                    "viewLevel": 1
                },
                "post": {
                    "viewName": "Post",
                    "viewId": "post",
                    "viewLevel": 2
                }
            }
        }
    }
}
```

We have already used the `#/Posts/{postId}` hash in our tests and a view called the *Post* page, so we will now add a route and a target to the routing configuration of the descriptor with these patterns. It is simply defining a mandatory routing parameter `postId` that we fill with the ID from the model when navigating. The target configuration references a view called `Post` with a view level deeper than the home page. For more information, see the Navigation and Routing [page 291] tutorial.

webapp/view/Worklist.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.bulletinboard.controller.Worklist"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:core="sap.ui.core"
    xmlns:semantic="sap.m.semantic">
    <semantic:FullscreenPage
        id="page"
        title="{i18n>worklistViewTitle}">
        <semantic:content>
            <Table …>
                …
                <items>
                    <ColumnListItem
                        vAlign="Middle"
                        type="Navigation"
                        press=".onPress">
                        …
                    </ColumnListItem>
                </items>
            </Table>
        </semantic:content>
        …
    </semantic:FullscreenPage>
</mvc:View>
```

We configure the table items to be of type `Navigation`, so a user can trigger the navigation by choosing an item. When a `press` event is triggered, the `onPress` handler is called to navigate to the *Post* page.

webapp/controller/Worklist.controller.js

```
sap.ui.define([
    './BaseController',
    'sap/ui/model/json/JSONModel',
    '../model/formatter',
    '../model/FlaggedType',
    'sap/m/library'
], function(BaseController, JSONModel, formatter, FlaggedType, mobileLibrary) {
    "use strict";
    return
BaseController.extend("sap.ui.demo.bulletinboard.controller.Worklist", {
        …
        /* =========================================================== */
        /* event handlers                                              */
        /* =========================================================== */
        …
                /**
         * Event handler when a table item gets pressed
         * @param {sap.ui.base.Event} oEvent the table selectionChange event
         * @public
         */
        onPress: function (oEvent) {
            this.getRouter().navTo("post", {
                // The source is the list item that got pressed
                postId:
oEvent.getSource().getBindingContext().getProperty("PostID")
            });

        },
        …
    });
});
```

The `press` handler function instructs the `router` to navigate to the `post` pattern with the `PostID` from the binding context of the currently selected item. This fills the mandatory URL parameter, navigates to the `post` page, and updates the hash automatically.

webapp/view/Post.view.xml (New)

```
<mvc:View
        controllerName="sap.ui.demo.bulletinboard.controller.Post"
        xmlns="sap.m"
        xmlns:mvc="sap.ui.core.mvc"
        xmlns:semantic="sap.m.semantic">
    <semantic:FullscreenPage
            id="page"
            busy="{postView>/busy}"
            busyIndicatorDelay="0"
            navButtonPress=".onNavBack"
            showNavButton="true"
            title="{i18n>objectTitle}">
        <semantic:content>
            <ObjectHeader
                    id="objectHeader"
                    title="{Title}"
                    number="{
                        path: 'Price',
                        formatter: '.formatter.numberUnit'
                    }"
```

```
                    numberUnit="{Currency}"
                    backgroundDesign="Translucent">
            </ObjectHeader>
        </semantic:content>
    </semantic:FullscreenPage>
</mvc:View>
```

We provide a minimalistic detail page showing only some fields of the selected post for now. In the test we use the following information:

- Control with the ID `page` on this view
- `title` of the post we navigate to
- *Back* button to navigate back to the home page

webapp/controller/Post.controller.js (New)

```
sap.ui.define([
    './BaseController',
    'sap/ui/model/json/JSONModel',
    '../model/formatter'
], function (BaseController, JSONModel, formatter) {
    "use strict";
    return BaseController.extend("sap.ui.demo.bulletinboard.controller.Post", {
        formatter: formatter,
        /* =========================================================== */
        /* lifecycle methods                                           */
        /* =========================================================== */
        /**
         * Called when the worklist controller is instantiated.
         * @public
         */
        onInit: function () {
            // Model used to manipulate control states. The chosen values make
sure,
            // detail page is busy indication immediately so there is no break in
            // between the busy indication for loading the view's meta data
            var oViewModel = new JSONModel({
                    busy: false
                });

this.getRouter().getRoute("post").attachPatternMatched(this._onPostMatched,
this);
            this.setModel(oViewModel, "postView");
        },
        /* =========================================================== */
        /* event handlers                                              */
        /* =========================================================== */
        /**
         * Navigates back to the worklist
         * @function
         */
        onNavBack: function () {
            this.myNavBack("worklist");
        },
        /* =========================================================== */
        /* internal methods                                            */
        /* =========================================================== */
        /**
         * Binds the view to the post path.
         *
         * @function
```

```
         * @param {sap.ui.base.Event} oEvent pattern match event in route
'object'
         * @private
         */
        _onPostMatched: function (oEvent) {
            var oViewModel = this.getModel("postView"),
                oDataModel = this.getModel();
            this.getView().bindElement({
                path: "/Posts('" + oEvent.getParameter("arguments").postId +
"')",
                events: {
                    dataRequested: function () {
                        oDataModel.metadataLoaded().then(function () {
                            // Busy indicator on view should only be set if
metadata is loaded,
                            // otherwise there may be two busy indications next
to each other on the
                            // screen. This happens because route matched
handler already calls '_bindView'
                            // while metadata is loaded.
                            oViewModel.setProperty("/busy", true);
                        });
                    },
                    dataReceived: function () {
                        oViewModel.setProperty("/busy", false);
                    }
                }
            });
        }
    });
});
```

The controller of the `Post` page needs to take care of the data binding when a navigation event has happened. In the `init` function of the controller we define a local view model and attach to the `routing` event. When the `routing` event is triggered, we bind the view to the post with the specified ID.

Step 10: Test Suite and Automated Testing

In this step, we will step back from our tests and application features that we have implemented so far and add another important piece of test code: The test suite page. A test suite can execute multiple tests and collect the results. This comes in handy for automatic tools in a continuous integration process.

Preview

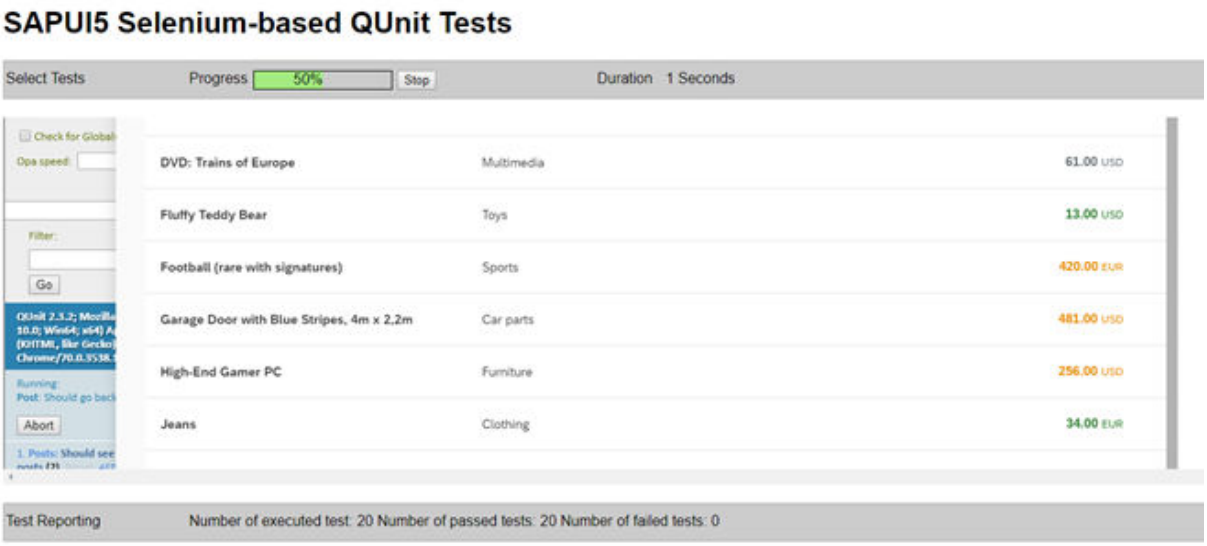

Figure 121: A Selenium runner for the test suite of the bulletin board

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 10.

webapp/test/testsuite.qunit.html (New)

```
<!DOCTYPE HTML>
<html>
<head>
    <title>QUnit test suite for Bulletin Board</title>
    <script src="resources/sap/ui/qunit/qunit-redirect.js"></script>
    <script src="testsuite.qunit.js" data-sap-ui-testsuite></script>
</head>
<body>
</body>
</html>
```

Create a new `testsuite.qunit.html` file. Here, you add the `testsuite.qunit.js` script, which we will define next, as a source.

webapp/test/testsuite.qunit.js (New)

```
window.suite = function() {
    "use strict";

    var oSuite = new parent.jsUnitTestSuite(),
        sContextPath = location.pathname.substring(0,
location.pathname.lastIndexOf("/") + 1);

    oSuite.addTestPage(sContextPath + "unit/unitTests.qunit.html");
    oSuite.addTestPage(sContextPath + "integration/opaTests.qunit.html");

    return oSuite;
};
```

This new `testsuite.qunit.js` file contains the logic for the QUnit tests. The coding is quite straightforward: We require the relevant QUnit files for redirecting to the central test suite and provide a configuration function `suite()` that is called automatically by the testrunner.

Inside this function, we add the QUnit pages for the app's unit and integration tests. For technical reasons, we have to provide an absolute path to the HTML pages so that the testrunner can execute them centrally. You can now run the `webapp/test/testsuite.qunit.html` file to check if all unit and integration tests are running fine with one URL.

> **i Note**
>
> A similar test suite can be configured as a pre-commit hook in local build environments or as a pre-submit hook in a continuous integration scenario on the central build server. Only when all tests run successfully, a new change is accepted and may be merged.
>
> Alternatively you can use a local test runner, such as Selenium or Karma, that automatically executes all tests whenever a file in the app project has been changed. All of these configurations run the tests and collect the resulting messages for further analysis. Therefore, it is very important to define meaningful test descriptions and success as well as error messages as you write your application tests.

Conventions

- Create a test suite app that triggers all your tests at once
- Run the test suite whenever you change the code of the app

Step 11: Testing User Input

In this step, we will write a test that simulates a user search. We will enter the search string into the search field and check if the correct results are shown in worklist table.

Preview

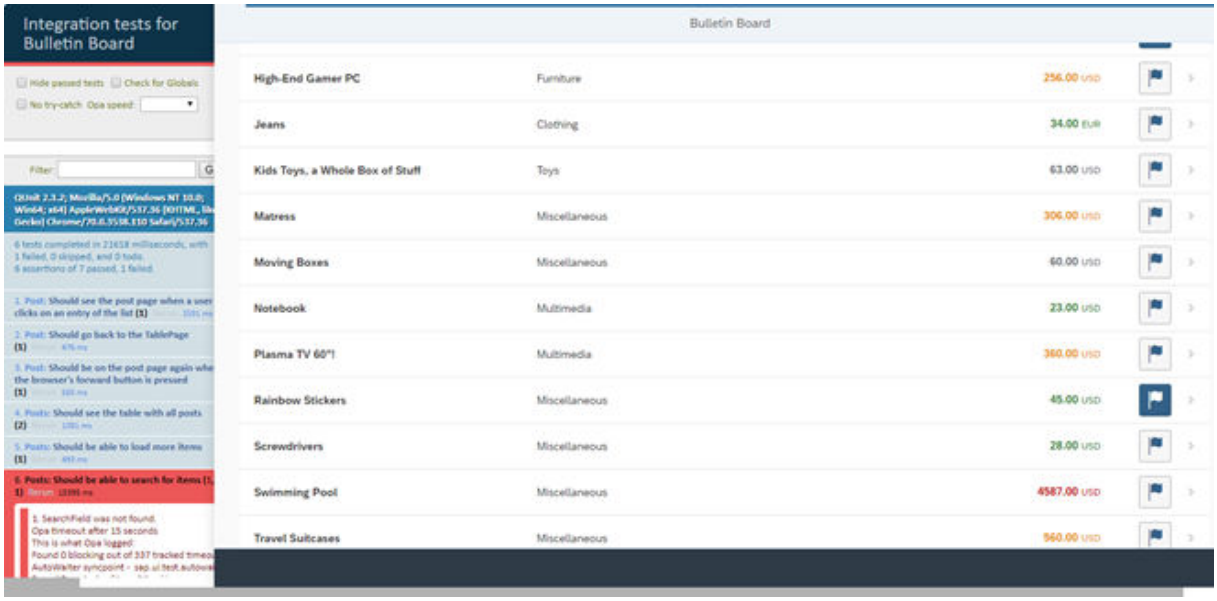

Figure 122: Testing user input in a search field

Coding

You can view and download all files in the Demo Kit at Testing - Step 11.

test/integration/WorklistJourney.js

```
sap.ui.define([
    "sap/ui/test/opaQunit",
    "./pages/Worklist"
], function (opaTest) {
    "use strict";
    QUnit.module("Posts");
    opaTest("Should see the table with all posts", function (Given, When, Then) {
        // Arrangements
        Given.iStartMyApp();
        // Assertions
        Then.onTheWorklistPage.theTableShouldHavePagination().
            and.theTitleShouldDisplayTheTotalAmountOfItems();
    });
    opaTest("Should be able to load more items", function (Given, When, Then) {
        //Actions
```

```
        When.onTheWorklistPage.iPressOnMoreData();
        // Assertions
        Then.onTheWorklistPage.theTableShouldHaveAllEntries();
    });
    opaTest("Should be able to search for items", function (Given, When, Then) {
        //Actions
        When.onTheWorklistPage.iSearchFor("Bear");

        // Assertions
        Then.onTheWorklistPage.theTableHasOneItem();

        // Cleanup
        Then.iTeardownMyApp();
    });
    }
);
```

In this example, we extend the `WorklistJourney.js` file with a new test `"Should be able to enter text into the search field"`. The action within this test simulates a user entering text into a search field, so we pass a search string `"Bear"` to this action. It is important to move the `Teardown` step to the last test, otherwise our app would be destroyed and the test would not be able to find the *Statistics* tab.

Delete `.and.iTeardownMyApp();` from the previous test in the file and add the new test case.

test/integration/pages/Worklist.js

```
sap.ui.require([
        'sap/ui/test/Opa5',
        'sap/ui/test/matchers/AggregationLengthEquals',
        'sap/ui/test/matchers/I18NText',
        'sap/ui/test/matchers/BindingPath',
        'sap/ui/demo/bulletinboard/test/integration/pages/Common',
        'sap/ui/test/actions/Press',
        'sap/ui/test/actions/EnterText'
    ],
    function (Opa5,
              AggregationLengthEquals,
              I18NText,
              BindingPath,
              Common,
              Press,
              EnterText) {
        "use strict";
        var sViewName = "Worklist",
            sTableId = "table";
        Opa5.createPageObjects({
            onTheWorklistPage: {
                baseClass: Common,
                actions: {
...
                    },

                    iSearchFor: function (sSearchString) {
                        return this.waitFor({
                            id: "searchField",
                            viewName: sViewName,
                            actions: new EnterText({
                                text: sSearchString
                            }),
                            errorMessage: "SearchField was not found."
                        });
                    }
```

```
                },
                assertions: {
                    theTableHasOneItem: function () {
                        return this.waitFor({
                            id: sTableId,
                            viewName: sViewName,
                            matchers: new AggregationLengthEquals({
                                name: "items",
                                length: 1
                            }),
                            success: function () {
                                Opa5.assert.ok(true, "The table contains one
corresponding entry");
                            },
                            errorMessage: "The table does not contain one item."
                        });
                    },
...
```

For the new test case we add an action `iEnterSearchStringIntoSearchField` and a new assertion `theTableShouldHaveCorrespondingEntries`.

In `iEnterSearchStringIntoSearchField`, we use the `EnterText` action and load the dependency `sap/ui/test/actions/EnterText`.

We define a `waitFor` statement with the current view and with the ID of our `SearchField`, which is stored as an internal variable. This is done in the same way as in the `iPressOnMoreData` action that we implemented in our first OPA test. But now we don't use the `EnterText` action. As soon as the `SearchField` is visible on the screen and can be interacted with, the `EnterText` action is invoked. If is is not invoked, an error message is displayed and the test fails.

The `assert` part is implemented in the same way as in our first OPA test. Again, we use the matchers to check the state. Here we check the number of items in the table resulting from the simulated search. According to our mock data, there should be only one item visible.

Conventions

Actions in OPA never contain a QUnit assertion.

Related Information

API Reference: `sap.ui.test.actions.EnterText`

Step 12: Adding a Search

We now add a search field to our bulletin board and define a filter that represents the search term. This is done similarly as in step 24 of the Walkthrough tutorial.

Preview

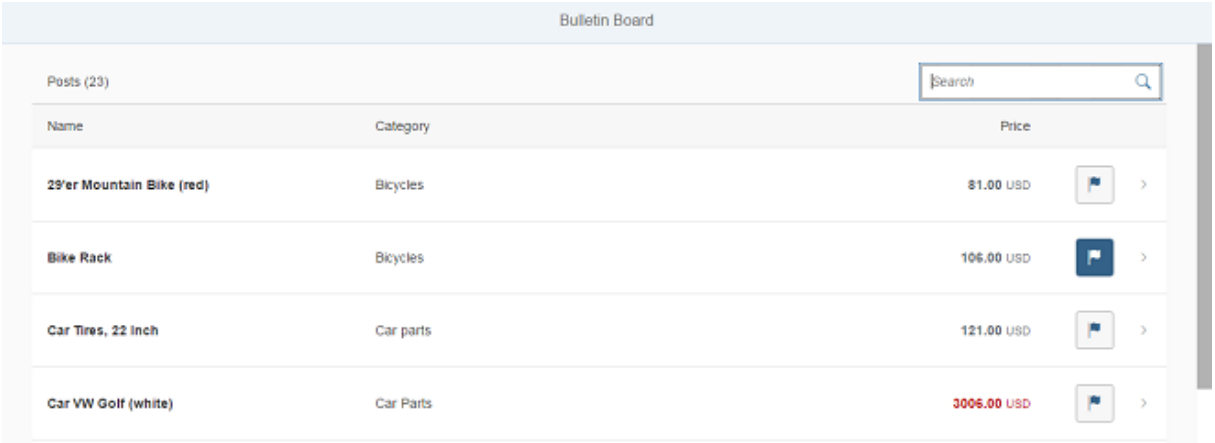

Figure 123: Search field

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 12.

webapp/view/Worklist.view.xml

```
...
         <Table
               id="table"
               width="auto"
               class="sapUiResponsiveMargin"
               growing="true"
               items="{
               path: '/Posts',
               sorter: {
                  path: 'Title',
                  descending: false
                  }
               }"
               busyIndicatorDelay="{worklistView>/tableBusyDelay}"
               updateFinished=".onUpdateFinished">
            <headerToolbar>
               <Toolbar>
                  <Label id="tableHeader" text="{worklistView>/
worklistTableTitle}"/>
```

```
                    <ToolbarSpacer />
                    <SearchField id="searchField" width="auto"
search=".onFilterPosts" />
                </Toolbar>
            </headerToolbar>
...
```

We add a `ToolbarSpacer` and a `SearchField` to the `headerToolbar` of our table.

webapp/controller/Worklist.controller.js

```
sap.ui.define([
    './BaseController',
    'sap/ui/model/json/JSONModel',
    '../model/formatter',
    '../model/FlaggedType',
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    'sap/m/library'
], function (BaseController, JSONModel, formatter, FlaggedType, Filter,
FilterOperator, mobileLibrary) {
    "use strict";
...
        onUpdateFinished: function (oEvent) {
            // update the worklist's object counter after the table update
            var sTitle,
                oTable = oEvent.getSource(),
                iTotalItems = oEvent.getParameter("total");
            // only update the counter if the length is final and
            // the table is not empty
            if (iTotalItems && oTable.getBinding("items").isLengthFinal()) {
                sTitle =
this.getResourceBundle().getText("worklistTableTitleCount", [iTotalItems]);
            } else {
                sTitle = this.getResourceBundle().getText("worklistTableTitle");
            }
            this.getModel("worklistView").setProperty("/worklistTableTitle",
sTitle);
        },
        onFilterPosts: function (oEvent) {

            // build filter array
            var aFilter = [];
            var sQuery = oEvent.getParameter("query");
            if (sQuery) {
                aFilter.push(new Filter("Title", FilterOperator.Contains,
sQuery));
            }

            // filter binding
            var oTable = this.byId("table");
            var oBinding = oTable.getBinding("items");
            oBinding.filter(aFilter);
        },
...
```

To enable filtering, we extend the controller with a method that applies the search term entered in the search field to the list binding, similarly as we did for `InvoiceList.controller.js` in step 24 of the Walkthrough tutorial.

Related Information

Step 42 of Walkthrough: Filtering [page 131]

Step 13: Testing User Interaction

In this step we want to write a test that simulates user interaction with an icon tab bar. We want to change the tab and check if the correct content is shown.

Preview

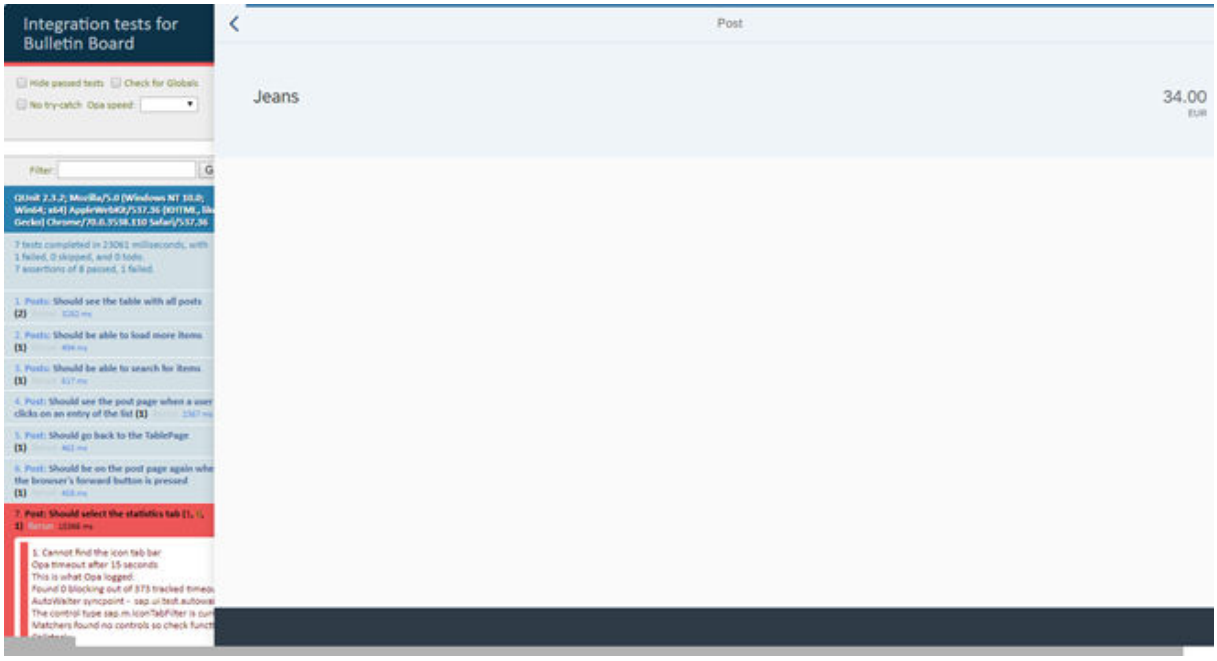

Figure 124: Test interacting with an icon tab bar

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 13.

test/integration/journeys/PostJourney.js

```
sap.ui.define([
    "sap/ui/test/opaQunit",
    "./pages/Worklist",
    "./pages/Browser",
```

```
    "./pages/Post"
], function (opaTest) {
    "use strict";
    …
    opaTest(…) {
        // Actions
            When.onTheBrowser.iPressOnTheForwardButton();

            // Assertions
            Then.onThePostPage.theTitleShouldDisplayTheName("Jeans");
        });
        opaTest("Should select the statistics tab", function (Given, When, Then)
{
            // Actions
            When.onThePostPage.iPressOnTheTabWithTheKey("statistics");
            // Assertions
            Then.onThePostPage.iShouldSeeTheViewCounter()
                .and.iTeardownMyApp();
        });
```

We extend the `PostJourney.js` file with a new test. It is important to move the `Teardown` to the last test, otherwise our app would be removed and the test would not be able to find the *Statistics* tab.

Delete `.and.iTeardownMyApp();` from the last test in the file and add the new test case

test/integration/pages/Post.js

```
sap.ui.define([
    'sap/ui/test/Opa5',
    'sap/ui/test/matchers/Properties',
    'sap/ui/test/actions/Press'
], function (Opa5, Properties, Press) {
    "use strict";

        var sViewName = "Post";

        Opa5.createPageObjects({
            onThePostPage: {
                actions: {
                    iPressTheBackButton: function () {
                        return this.waitFor({
                            id: "page",
                            viewName: sViewName,
                            actions: new Press(),
                            errorMessage: "Did not find the nav button on object
page"
                        });
                    },
                    iPressOnTheTabWithTheKey: function (sKey) {
                        return this.waitFor({
                            controlType: "sap.m.IconTabFilter",
                            viewName : sViewName,
                            matchers: new Properties({
                                key: sKey
                            }),
                            actions: new Press(),
                            errorMessage: "Cannot find the icon tab bar"
                        });

                    }
                },
                assertions: {
```

```
                    theTitleShouldDisplayTheName: function (sName) {
                        return this.waitFor({
                            id: "objectHeader",
                            viewName: sViewName,
                            matchers: new Properties({
                                title: sName
                            }),
                            success: function (oPage) {
                                Opa5.assert.ok(true, "was on the remembered
detail page");
                            },
                            errorMessage: "The Post " + sName + " is not shown"
                        });
                    },

                    iShouldSeeTheViewCounter: function () {
                        return this.waitFor({
                            id: "viewCounter",
                            viewName: sViewName,
                            success: function () {
                                Opa5.assert.ok(true, "The view counter was
visible");
                            },
                            errorMessage: "The view counter could not be found"
                        });
                    }
                }
            }
        });
    });
```

To change the selected tab, you set the selected key of the `sap.m.IconTabBar`. We have looked up the `setSelectedKey` function in the API documentation of the control, so we know that we can write a `waitFor` statement that makes use of it.

There is no uniform way of triggering user interactions with OPA. In most cases it is sufficient to use the API of the controls, e.g. setting a value. Note however, that calling the API methods of a control might not trigger the same events as when pressing the control.

In the `assert` part we add a new assertion for checking the visibility of a control with the ID `viewCounter`. Each `waitFor` statement checks if the control is rendered and visible unless you set `visible: false`. Therefore, we only use the `ok(true)` assertion in the success handler of the `waitFor` statement since QUnit expects at least one assertion for a test.

Conventions

- Actions in OPA never contain a QUnit assertion

Related Information

API Reference: `sap.m.IconTabBar`

API Overview and Samples: `sap.m.IconTabBar`

Step 14: Adding Tabs

We want to display statistics for posts, for example, how many times it was viewed. To achieve this, we implement an icon tab bar with an *Info* tab and a *Statistics* tab. The existing content should be placed on the *Info* tab and the view count on the *Statistics* tab.

Preview

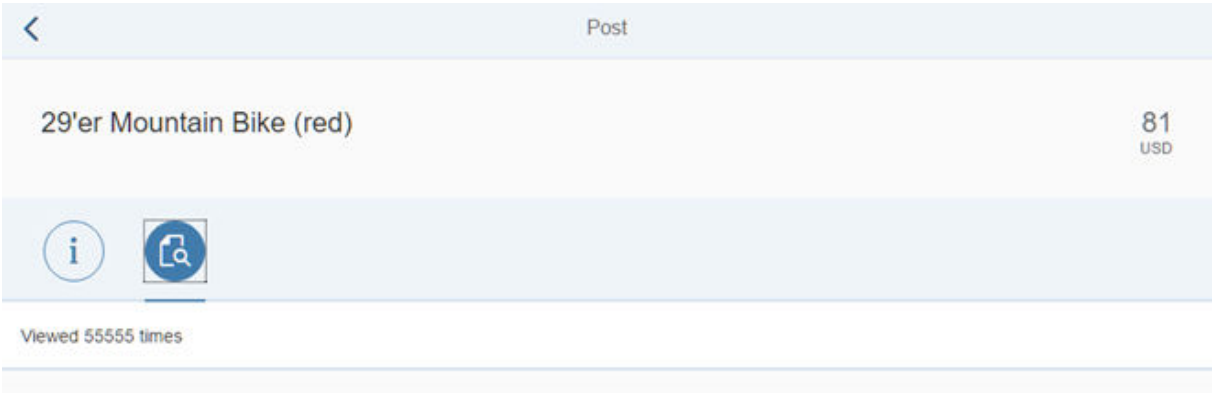

Figure 125: An icon tab bar with statistics

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 14.

view/Post.view.xml

```
<mvc:View
      controllerName="sap.ui.demo.bulletinboard.controller.Post"
      xmlns="sap.m"
      xmlns:form="sap.ui.layout.form"
      xmlns:mvc="sap.ui.core.mvc"
      xmlns:semantic="sap.m.semantic">
   <semantic:FullscreenPage
         id="page"
         busy="{postView>/busy}"
         busyIndicatorDelay="0"
         navButtonPress=".onNavBack"
         showNavButton="true"
         title="{i18n>objectTitle}">
      <semantic:content>
         <ObjectHeader
               id="objectHeader"
               title="{Title}"
               number="{
                  path: 'Price',
                  formatter: '.formatter.numberUnit'
               }"
```

```
                numberUnit="{Currency}"
                backgroundDesign="Translucent">
            </ObjectHeader>
            <IconTabBar id="iconTabBar"
                     expanded="{device>/isNoPhone}"
                     class="sapUiNoContentPadding">
               <items>
                  <IconTabFilter icon="sap-icon://hint" key="info" >
                     <form:SimpleForm>
                        <form:content>
                           <Label text="{i18n>postDateLabel}"/>
                           <Text text="{Timestamp}"/>
                           <Label text="{i18n>postDescriptionLabel}"/>
                           <Text text="{Description}"/>
                        </form:content>
                     </form:SimpleForm>
                  </IconTabFilter>
                  <IconTabFilter icon="sap-icon://inspection" key="statistics">
                     <Text text="Viewed 55555 times" id="viewCounter"/>
                  </IconTabFilter>
               </items>
            </IconTabBar>
         </semantic:content>
      </semantic:FullscreenPage>
</mvc:View>
```

We add a `sap.m.IconTabBar` with the two tabs `info` and `statistics`. The `statistics` tab we have already referred to in our test case.

Inside the first tab there is a `sap.ui.layout.form.SimpleForm` with a date and a description field that are mapped to the model data. In the second tab we place a new `Text` control.

In this very simple example, we just put a static text in the tab. In a real application, we would bind the value to the model.

webapp/i18n/i18n.properties

```
#~~~ Object View ~~~~~~~~~~~~~~~~~~~~~~~~~
#XTIT: Object view title
objectTitle=Post

#XTIT: Post view date label
postDateLabel=Posted At

#XTIT: Post view description label
postDescriptionLabel=Description
#~~~ Footer Options ~~~~~~~~~~~~~~~~~~~~~~
```

We add the missing texts to the `i18n.properties` file.

Step 15: Writing a Short Date Formatter Using TDD

It's now time to improve the content of the *Info* tab. We want to see the *Posted At* date in a formatted way. Based on the age of the post, we either display the time, a textural representation of the day, or the date only.

Preview

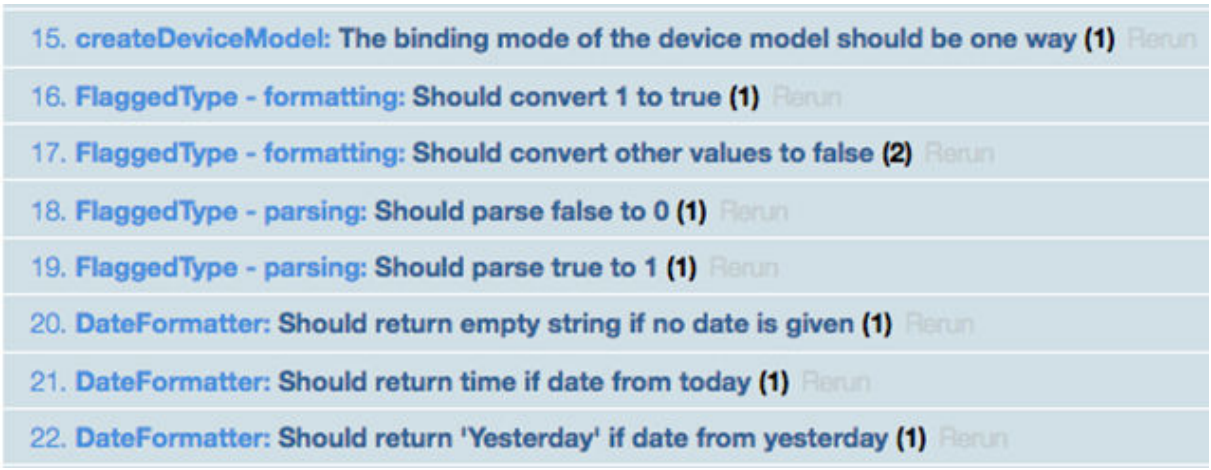

Figure 126: Unit tests of the formatter

Depending on the current date, we distinguish four different formatting categories, as shown in the table below:

Table 6: Formatting Categories

Category	Sample Input	Expected Output (for `en-US`)
Today	`2013/02/13 12:05:20`	`12:05 PM`
Yesterday	`2013/02/12 12:05:20`	`Yesterday`
Last 7 days	`2013/02/08 12:05:20`	`Friday`
Others	`2011/02/05 12:05:20`	`Dec 5, 2011`

As you can see, we have many different cases, and our formatter contains real logic.

We test this in a unit test. In this step we will follow an iterative approach. We first write a failing test and immediately fix it by adding the production code to make the test pass. Then the next iteration starts. We do not write more than one failing unit test at once.

> **i Note**
>
> There are many benefits of consequently applying the test-driven development (TDD) methodology, for example, very fast feedback, you can execute your tests after each change and get immediate feedback if the tests run green. You also spend less time debugging and for analysis. We recommend that you get familiar with TDD and clean code practices. In this step you get a first impression how TDD results in better

> separation of concerns, APIs, handling of dependencies, code reuse, and a test suite growing together with the code.

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 15.

webapp/test/unit/AllTests.js

```
sap.ui.define([
    "./model/models",
    "./model/formatter",
    "./model/FlaggedType",
    "./model/DateFormatter"
], function() {
    "use strict";
});
```

First, we add the new test file we are about to create to the `AllTests.js` file.

webapp/model/DateFormatter.js (New)

```
sap.ui.define([
    "sap/ui/base/Object"
], function(Object) {
        return Object.extend("sap.ui.demo.bulletinboard.model.DateFormatter", {
    });
});
```

We create an empty hull for our formatter implementation first so that we can include it in our test. It does not contain any logic yet but simply extends an SAPUI5 base object.

webapp/test/unit/model/DateFormatter.js (New)

```
sap.ui.define([
    "sap/ui/demo/bulletinboard/model/DateFormatter"
], function(DateFormatter) {
    QUnit.module("DateFormatter");
    QUnit.test("initial", function(assert) {
        assert.ok(new DateFormatter());
    });
});
```

And we create our test that checks if there is a `DateFormatter` object. Now we can execute our unit tests. We see that this test is failing as the object does not exist in our code yet.

webapp/test/unit/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/demo/bulletinboard/model/DateFormatter"
], function(DateFormatter) {
    QUnit.module("DateFormatter");
    QUnit.test("Should return empty string if no date is given",
function(assert) {
        var oFormatter = new DateFormatter();
        var sFormattedDate = oFormatter.format(null);
        assert.strictEqual(sFormattedDate, "");
    });
});
```

Now we implement a test for the API of the format function. We assume it will have a `Date` object as input parameter. In the first step, the test verifies that the format function returns an empty string if we pass `null`.

webapp/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/base/Object"
], function(Object) {
        return Object.extend("sap.ui.demo.bulletinboard.model.DateFormatter", {
            format: function() {
                return "";
            }
        });
    }
);
```

Now we fix our test again by returning the expected string.

Dependency Injection:

webapp/test/unit/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/demo/bulletinboard/model/DateFormatter",
    "sap/ui/core/Locale"
], function(DateFormatter, Locale) {
    QUnit.module("DateFormatter");
    QUnit.test("Should return empty string if no date is given",
function(assert) {
        var oFormatter = new DateFormatter({
            locale : new Locale("en-US")
        });
        var sFormattedDate = oFormatter.format(null);
        assert.strictEqual(sFormattedDate, "");
    });
    QUnit.test("Should return time if date from today", function(assert) {
        var oFormatter = new DateFormatter({
            locale : new Locale("en-US")
```

```
        });
        var oDate = new Date(2015, 2, 14, 12, 5, 0, 0);
        var sFormattedDate = oFormatter.format(oDate);
        assert.strictEqual(sFormattedDate, "12:05 PM");
    });
});
```

Here our test expects that the date is displayed as time when the post is from today. If we rely on the browser language the test would be fragile. It will fail in some languages. To avoid this, we pass the locale settings to the formatter's constructor. The test will use a fixed locale `en-US` in order to remain stable. This mechanism is called **Dependency Injection**.

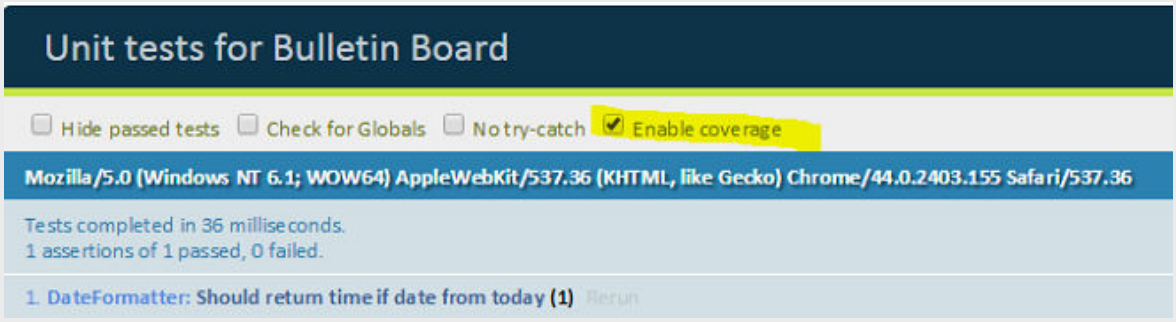
webapp/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/base/Object",
    "sap/ui/core/format/DateFormat"
], function(Object, DateFormat) {
    return Object.extend("sap.ui.demo.bulletinboard.model.DateFormatter", {
        constructor: function(oProperties) {
            this.timeFormat = DateFormat.getTimeInstance({
                style: "short"
            }, oProperties.locale);
            },
        format: function(oDate) {
            if (!oDate) {
                return "";
            }
                return this.timeFormat.format(oDate);
            }
        });
    }
);
```

In the implementation we use the `DateFormat` of SAPUI5 to create a short date. The locale is passed on to the `getTimeInstance` function.

i Note

The implementation should not do more than the current tests covers. This makes sure you cover all the code paths. You can enable the code coverage by selecting the *Enable coverage* checkbox.



It will show the lines covered by your tests (white) and the ones that were not covered (red). For the single test above the coverage looks like this. The red line is already covered by the previous test so in total we have a test coverage of 100%.

Refactoring:

webapp/test/unit/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/demo/bulletinboard/model/DateFormatter",
    "sap/ui/core/Locale"
], function(DateFormatter, Locale) {
    var oFormatter = null;
    QUnit.module("DateFormatter", {
        beforeEach: function() {
            oFormatter = new DateFormatter({
                locale: new Locale("en-US")
            });
        }
    });
    QUnit.test("Should return empty string if no date is given",
function(assert) {
        /*Delete in your code: var oFormatter = new DateFormatter();
        ...
    });
    QUnit.test("Should return time if date from today", function(assert) {
        /*Delete in your code: var oFormatter = new DateFormatter({
        /*Delete in your code:     locale: new Locale("en-US")
        /*Delete in your code: });
        ...
    });
});
```

Our tests are running so we can start refactoring our code. Since we need the `DateFormatter` object in every test case we will move it to the QUnit module's `beforeEach` function. As the name suggests, the function is invoked before each test so we may use it to save some code we need in every test.

Dependency Injection to Get Independent from System Time:

webapp/test/unit/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/demo/bulletinboard/model/DateFormatter"
    "sap/ui/core/Locale"
], function(DateFormatter, Locale) {
    var oFormatter = null;
    QUnit.module("DateFormatter", {
        beforeEach: function() {
            oFormatter = new DateFormatter({
                now : function() {
                    return new Date(2015, 2, 14, 14, 0, 0, 0).getTime();
                },
                locale : new Locale("en-US")
            });
        }
    });
    ...
    QUnit.test("Should return 'Yesterday' if date from yesterday",
function(assert) {
        var oDate = new Date(2015, 2, 13);
```

```
        var sFormattedDate = oFormatter.format(oDate);
        assert.strictEqual(sFormattedDate, "Yesterday");
    });
});
```

The next test verifies that `Yesterday` is returned for yesterday's date. To keep the test independent of the system time, we pass on a stable date to the formatter.

webapp/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/base/Object",
    "sap/ui/core/format/DateFormat"
], function(Object, DateFormat) {
    return Object.extend("sap.ui.demo.bulletinboard.model.DateFormatter", {
        constructor : function(oProperties) {
            this.timeFormat = DateFormat.getTimeInstance({
                style : "short"
            }, oProperties.locale);
            this.now = oProperties.now;
        },
        format : function(oDate) {
            if (!oDate) {
                return "";
            }
            var iElapsedDays = this._getElapsedDays(oDate);
            if (iElapsedDays === 0) {
                return this.timeFormat.format(oDate);
            } else if (iElapsedDays === 1) {
                return "Yesterday";
            }
            return this.dateFormat.format(oDate);
        },
        _getElapsedDays : function(oDate) {
            var iElapsedMilliseconds = this.now() - oDate.getTime();
            var fElapsedDays = iElapsedMilliseconds / 1000 / 60 / 60 / 24;
            return Math.floor(fElapsedDays);
        }
    });
});
```

In the implementation we add a calculation for determining how many days passed. If zero days passed, the format function is called, and if one day passed `Yesterday` is returned. Currently we skip reading "Yesterday" from the i18n model to keep the example simple.

Boundary Testing:

webapp/test/unit/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/demo/bulletinboard/model/DateFormatter",
    "sap/ui/core/Locale"
], function(DateFormatter, Locale) {
    var oFormatter = null;
```

```
    ...
    QUnit.test("Should return day of the week if date < 7 days ago",
function(assert) {
        var oDate = new Date(2015, 2, 8);
        var sFormattedDate = oFormatter.format(oDate);
        assert.strictEqual(sFormattedDate, "Sunday");
    });
});
```

The next test verifies that the day of the week is returned. As test input we take a value at the boundary: Sunday is one day before a different formatting pattern should be applied.

webapp/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/base/Object",
    "sap/ui/core/format/DateFormat"
], function(Object, DateFormat) {
    return Object.extend("sap.ui.demo.bulletinboard.model.DateFormatter", {
        constructor: function(oProperties) {
            this.timeFormat = DateFormat.getTimeInstance({
                style: "short"
            }, oProperties.locale);
            this.weekdayFormat = DateFormat.getDateInstance({
                pattern: "EEEE"
            }, oProperties.locale);
            this.now = oProperties.now;
        },
        format: function(oDate) {
            if (!oDate) {
                return "";
            }
            var iElapsedDays = this._getElapsedDays(oDate);
            if (iElapsedDays === 0) {
                return this.timeFormat.format(oDate);
            } else if (iElapsedDays === 1) {
                return "Yesterday";
            } else if (iElapsedDays < 7) {
                return this.weekdayFormat.format(oDate);
            }
        }
    …
```

Now we define a new format in our constructor, the `weekdayFormat`. In the format function we apply the format if the elapsed days are smaller than 7.

webapp/test/unit/model/DateFormatter.js

```
sap.ui.define([
    "sap/ui/demo/bulletinboard/model/DateFormatter",
    "sap/ui/core/Locale"
], function(DateFormatter, Locale) {
    var oFormatter = null;
    ...
    QUnit.test("Should return date w/o time if date > 7 days ago",
function(assert) {
```

```
        var oDate = new Date(2015, 2, 7);
        var sFormattedDate = oFormatter.format(oDate);
        assert.strictEqual(sFormattedDate, "Mar 7, 2015");
    });
});
```

In the next test we verify that the date is formatted as date without time. Again, we take a value at the boundary.

webapp/model/DateFormatter.js

```
…
        constructor: function(oProperties) {
            this.timeFormat = DateFormat.getTimeInstance({
                style : "short"
            }, oProperties.locale);
            this.weekdayFormat = DateFormat.getDateInstance({
                pattern : "EEEE"
            }, oProperties.locale);
            this.dateFormat = DateFormat.getDateInstance({
                style : "medium"
            }, oProperties.locale);
            this.now = oProperties.now;
        },
        format: function(oDate) {
            if (!oDate) {
                return "";
            }
            var iElapsedDays = this._getElapsedDays(oDate);
            if (iElapsedDays === 0) {
                return this.timeFormat.format(oDate);
            } else if (iElapsedDays === 1) {
                return "Yesterday";
            } else if (iElapsedDays < 7) {
                return this.weekdayFormat.format(oDate);
            } else {
                return this.dateFormat.format(oDate);
            }
        },
    …
```

In the implementation, we use a different `style` property for instantiating the `dateFormat` property. We call the format of this instance for dates that are more than 6 days in the past.

Although our formatter depends on system time and locale settings, our tests are very easy to read and maintain. We wrote blackbox tests, providing only the input and expecting a certain output without knowing the implementation details. The `DateFormatter` does not actively resolve the dependencies to the system time and locale settings. Instead, it asks its creator to pass the dependencies along in the constructor. In the next step, we have to bring the pieces together.

Step 16: Adding the Date Formatter

Our formatter does its job, but it is not yet used. In this step we will use it.

Preview

Figure 127: Date formatter in action

Coding

You can view and download all files in the *Samples* in the Demo Kit at Testing - Step 16.

webapp/view/Post.view.xml

```
…
<IconTabBar id="iconTabBar"
            expanded="{device>/isNoPhone}"
            class="sapUiResponsiveContentPadding">
    <items>
        <IconTabFilter icon="sap-icon://hint" key="info">
            <form:SimpleForm>
                <form:content>
                    <Label text="{i18n>postDateLabel}"/>
                    <Text text="{
                        path: 'Timestamp',
                        formatter: '.formatter.date'
                    }"/>
                    <Label text="{i18n>postDescriptionLabel}"/>
                    <Text text="{Description}"/>
                </form:content>
            </form:SimpleForm>
        </IconTabFilter>
        …
    </items>
</IconTabBar>
…
```

On the *Info* tab we bind the date field to a format method `.formatter.date` of the controller of the view. The leading `.` indicates that the function is defined on the controller instance.

webapp/model/formatter.js

```
sap.ui.define([ "sap/ui/demo/bulletinboard/model/DateFormatter" ], function
(DateFormatter) {
    ...
    return {
        ...
        numberUnit: function(sValue) {
            ...
        },
        date: function(date) {
            return new DateFormatter({now: Date.now}).format(date);
        }
    };
});
```

In the `formatter.js file`, create an instance of the previously implemented `DateFormatter` and provide the necessary dependencies.

Now run the app again to see that the formatter is applied on the post date of the detail page.

> **i** Note
>
> The files that create objects with dependencies should be kept simple. They do not have multiple code paths caused by if-else statements or loops. To test these components, just a few simple integration tests, or merely smoke tests, are sufficient. We already know that the `DateFormatter` does the job right for all the different cases.

Summary

You should now be familiar with the major development paradigms and concepts of SAPUI5 and have created a very simple first app. You are now ready to build a proper app based on what you've learned.

Mock Server

In this tutorial, we will explore some advanced features of the mock server.

If no OData service is available or you simply don't want to depend on the OData backend connectivity for your development and tests, the mock server can mimic the OData back-end calls. It is designed to simulate an OData provider by intercepting the HTTP communication made to the server, and providing a fake output. All this is transparent to the data binding and usage of OData model.

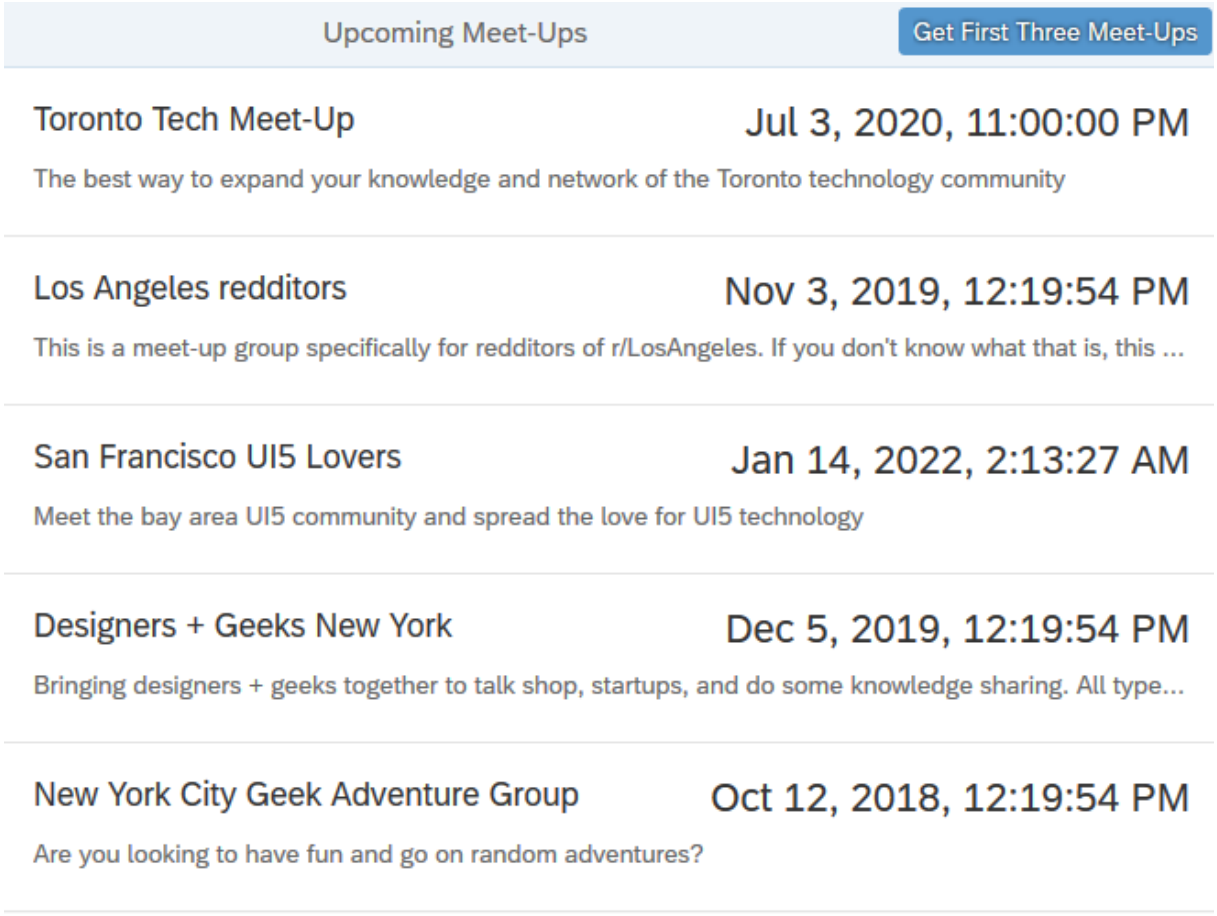
In certain scenarios, using only the built-in OData simulation of the mock server is insufficient for completely server-independent tests. For example, if your application is using an OData feature that is not supported by

the mock server, or if your application invokes a function import that depends on server specific implementation (and thus is also not simulated generically). We will demonstrate how to use function callbacks in order to change existing mock requests.

Additionally, we will demonstrate how to mock an additional request that is not simulated out of the box by the SAPUI5 mock server.

> ⚠ Caution
>
> The tutorial describes how to use some advanced features of the mock server, disregarding the legal aspects of shipping mock data. Usually the mock data and mock server invocation is done in a test folder that is not shipped to customers. Be very careful that you don't ship mock data!

Preview



> → Tip
>
> You don't have to do all tutorial steps sequentially, you can also jump directly to any step you want. Just download the code from the previous step, and start there.

You can view and download the files for all steps in the Demo Kit at Mock Server. Copy the code to your workspace and make sure that the application runs by calling the `webapp/index.html` file. Depending on your development environment you might have to adjust resource paths and configuration entries.

For more information check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]

Prerequisites

This tutorial assumes you have access to the SAP Web IDE either by having a trial account or a customer account. For more information, see App Development Using SAP Web IDE [page 44].

You should also be familiar with the concepts explained in the Walkthrough [page 69] tutorial and with the OData specification.

Related Information

Mock Server [page 1222]

Step 1: Initial App Without Data

We start with a simple app scenario with a list of items bound to an OData service. Since the OData service is not available yet on a real server, we will use the mock server to simulate both data and data calls.

For this very simple tutorial app we will use an OData service called `NerdMeetups` that lists meet-up groups according to location, date, topic, etc. The app will display a simple list populated by a function import call to display only upcoming meet-ups (meet-ups with an event date greater to the current date).

Additionally, a button will fetch the first three meet-ups (using a custom URL parameter called `first`). This exercise simply shows an app with no data retrieved from the back end. This can happen when the back end is down, or when the service is not implemented yet.

Usually you start the development of an app with local mock data first. This way you can continue implementing the application logic without depending on the back end readiness and connectivity.

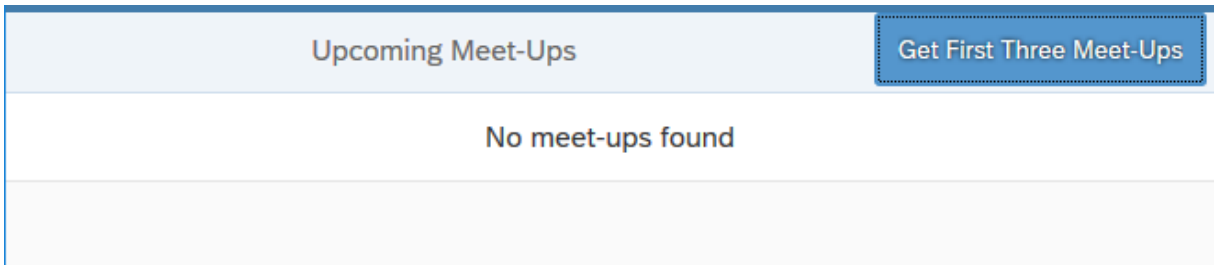

Figure 128: The initial app

Coding

To set up your project for this tutorial, download the files for *Step 1* in the Demo Kit at Mock Server - Step 1. Copy the code to your workspace and make sure that the application runs by calling the `webapp/test/mockServer.html` file.

Depending on your development environment you might have to adjust resource paths and configuration entries. The project structure and the files coming with this tutorial are explained in detail in the Walkthrough [page 69] tutorial.

You should have the same files as displayed in the following figure:

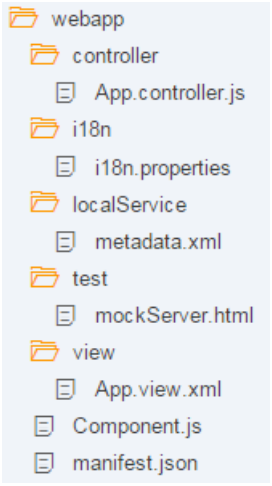

Figure 129: Folder structure with downloaded files

Step 2: Creating a Mock Server to Simulate Data

In this step, we use the mock server to add data to our app without dependency to any remote server or system.

Preview

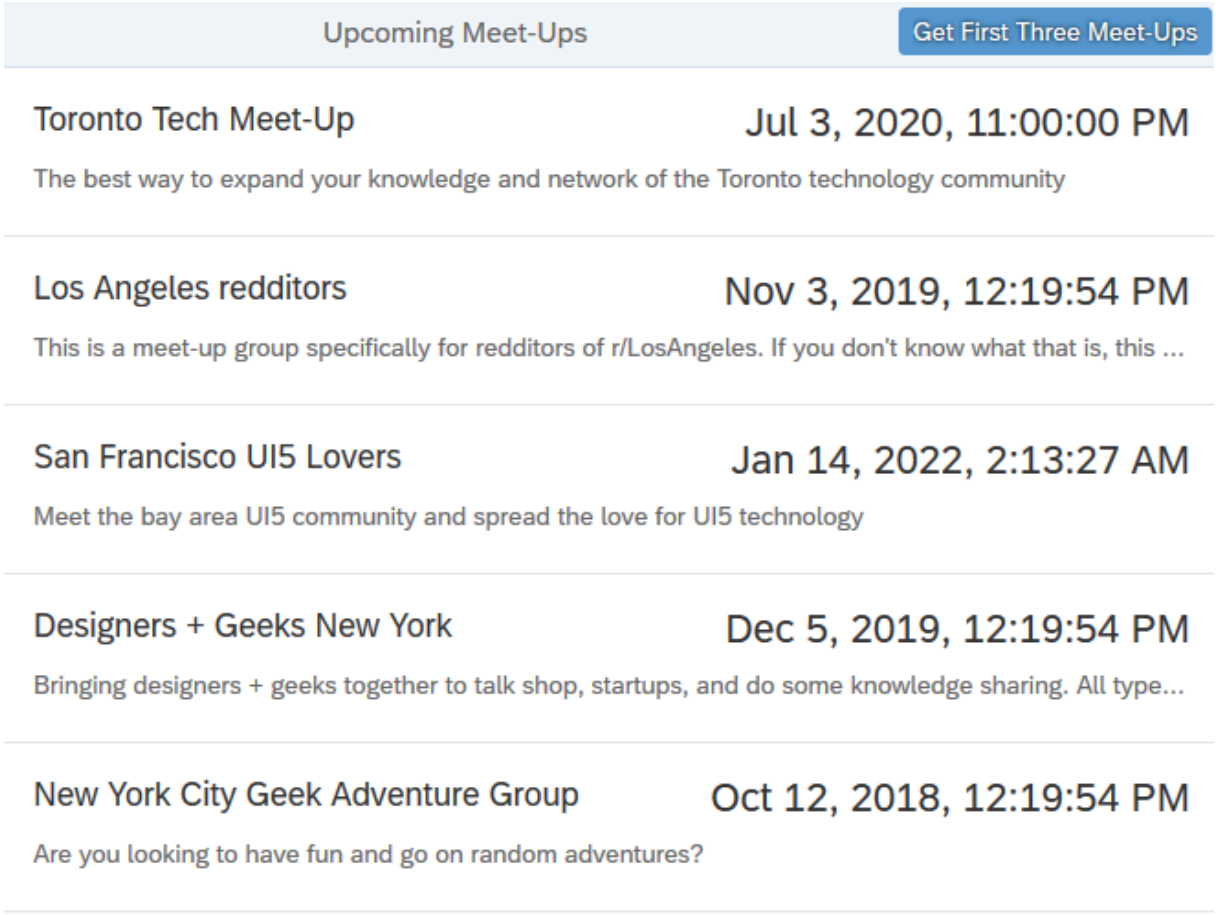

Figure 130: The app now contains data

Coding

You can view and download all files in the Demo Kit at Mock Server - Step 2.

webapp/test/mockServer.html

```
<!DOCTYPE HTML>
<html>
```

```
<head>
    <meta charset="utf-8">
    <meta name="viewport" content="width=device-width, initial-scale=1.0">
    <title>Mock Server Tutorial</title>
    <script id="sap-ui-bootstrap"
        src="resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.MockServer": "../"
        }'
        data-sap-ui-oninit="module:sap/ui/demo/MockServer/test/initMockServer"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true">
    </script>
</head>
<body class="sapUiBody">
    <div data-sap-ui-component data-name="sap.ui.demo.MockServer" data-
id="container" data-settings='{"id" : "MockServer"}'></div>
</body>
</html>
```

We use this file to run our app in test mode with mock data. The new artifact `initMockServer` performs the required set up steps before the application component is instantiated. By doing so, we can catch all requests that would go to the real service and process it locally with our mock server when the app is launched with the `webapp/test/mockServer.html`.

> **i Note**
>
> A productive application does not contain the mock server code and thus connects to the real service instead. The HTML page above is defined only for local testing and to be called in automated tests. The application coding itself is unchanged and does not know the difference between the real and the mocked back-end service.
>
> The mock server does not need to be called from anywhere else in our code so we use `sap.ui.require` to load dependencies asynchronously without defining a global namespace.

webapp/test/initMockServer.js

```
sap.ui.define([
    "sap/ui/demo/MockServer/localService/mockserver"
], function (mockserver) {
    "use strict";
    // initialize the mock server
    mockserver.init();
    // initialize the embedded component on the HTML page
    sap.ui.require(["sap/ui/core/ComponentSupport"]);
});
```

We load a dependency to a file called `mockserver.js` that is located in the `webapp/localService` folder. This file contains our local mock server. It is immediately called with the `init` method before we initialize the application component.

webapp/localService/metadata.xml

```
<?xml version="1.0" encoding="utf-8" standalone="yes"?>
<edmx:Edmx Version="1.0"
    xmlns:edmx="http://schemas.microsoft.com/ado/2007/06/edmx">
    <edmx:DataServices
        xmlns:m="http://schemas.microsoft.com/ado/2007/08/dataservices/metadata"
m:DataServiceVersion="1.0">
        <Schema Namespace="NerdMeetup.Models"
            xmlns:d="http://schemas.microsoft.com/ado/2007/08/dataservices"
            xmlns:m="http://schemas.microsoft.com/ado/2007/08/dataservices/
metadata"
            xmlns="http://schemas.microsoft.com/ado/2006/04/edm">
            <EntityType Name="Meetup">
                <Key>
                    <PropertyRef Name="MeetupID" />
                </Key>
                <Property Name="MeetupID" Type="Edm.Int32" Nullable="false" />
                <Property Name="Title" Type="Edm.String" Nullable="true" />
                <Property Name="EventDate" Type="Edm.DateTime"
Nullable="false" />
                <Property Name="Description" Type="Edm.String" Nullable="true" />
                <Property Name="HostedBy" Type="Edm.String" Nullable="true" />
                <Property Name="ContactPhone" Type="Edm.String"
Nullable="true" />
                <Property Name="Address" Type="Edm.String" Nullable="true" />
                <Property Name="Country" Type="Edm.String" Nullable="true" />
                <Property Name="Latitude" Type="Edm.Double" Nullable="false" />
                <Property Name="Longitude" Type="Edm.Double" Nullable="false" />
                <Property Name="HostedById" Type="Edm.String" Nullable="true" />
                <Property Name="Location"
Type="NerdMeetup.Models.LocationDetail" Nullable="false" />
            </EntityType>
            <ComplexType Name="LocationDetail" />
            <EntityContainer Name="NerdMeetups"
m:IsDefaultEntityContainer="true">
                <EntitySet Name="Meetups"
EntityType="NerdMeetup.Models.Meetup" />
                <FunctionImport Name="FindUpcomingMeetups" EntitySet="Meetups"
ReturnType="Collection(NerdMeetup.Models.Meetup)" m:HttpMethod="GET" />
            </EntityContainer>
        </Schema>
    </edmx:DataServices>
</edmx:Edmx>
```

The `metadata` file contains information about the service interface and does not need to be written manually. It defines a `Meetup` entity, a `Meetups` entity set and a function import definition.

webapp/localService/mockdata/Meetups.json (New)

```
[{
    "MeetupID": 1,
    "Title": "Toronto Tech Meet-Up",
    "EventDate": "/Date(1593810000000)/",
    "Description": "The best way to expand your knowledge and network of the
Toronto technology community"
},
{
    "MeetupID": 2,
    "Title": "Los Angeles redditors",
```

```
    "EventDate": "/Date(1572779994000)/",
    "Description": "This is a meet-up group specifically for redditors of r/
LosAngeles. If you don't know what that is, this isn't the meet-up you're
looking for"
}, {
    "MeetupID": 3,
    "Title": "San Francisco UI5 Lovers",
    "EventDate": "/Date(1642122807784)/",
    "Description": "Meet the bay area UI5 community and spread the love for UI5
technology"
}, {
    "MeetupID": 4,
    "Title": "Designers + Geeks New York",
    "EventDate": "/Date(1575544794000)/",
    "Description": "Bringing designers + geeks together to talk shop, startups,
and do some knowledge sharing. All types of designers + geeks welcome"
}, {
    "MeetupID": 5,
    "Title": "New York City Geek Adventure Group",
    "EventDate": "/Date(1539339594000)/",
    "Description": "Are you looking to have fun and go on random adventures?"
}]
```

The `Meetups.json` file is automatically read by the mock server later in this step. It represents a flat array of `Meetup` items.

webapp/localService/mockserver.js (New)

```
sap.ui.define([
    "sap/ui/core/util/MockServer",
    "sap/base/Log"
], function(MockServer, Log) {
    "use strict";

    return {
        /**
         * Initializes the mock server.
         * You can configure the delay with the URL parameter "serverDelay".
         * The local mock data in this folder is returned instead of the real
data for testing.
         * @public
         */
        init: function() {
            // create
            var oMockServer = new MockServer({
                rootUri: "/"
            });

            // simulate against the metadata and mock data
            oMockServer.simulate("../localService/metadata.xml", {
                sMockdataBaseUrl: "../localService/mockdata",
                bGenerateMissingMockData: true
            });

            // start
            oMockServer.start();

            Log.info("Running the app with mock data");
        }

    };

});
```

Now we can write the code to initialize the mock server that will simulate the requests instead of the real server. We load the `MockServer` module as a dependency and create a helper object that defines an `init` method to start the server. This method is called before the Component initialization in the `mockServer.html` file above. The `init` method creates a `MockServer` instance with the same URL as the real service. The URL in configuration parameter `rootURI` is now served by our test server instead of the real service.

Next, we set two global configuration settings for all `MockServer` instances that tell the server to respond automatically and introduce a delay of one second to imitate a typical server response time.

In order to simulate a manual back-end call we can simply call the `simulate` method on the `MockServer` instance with the path to our newly created `metadata.xml` file. This will read the test data from our local file system and set up the URL patterns that will mimic the real service. The first parameter is the path to the service `metadata.xml` document. The second parameter is an object with the following properties:

- `sMockdataBaseUrl`: path where to look for mock data files in JSON format
- `bGenerateMissingMockData`: Boolean property to tell the `MockServer` to use auto-generated mock data in case no JSON files are found.

We call the function `start` on the mock server instance. From this point on, each request matching the URL pattern `rootURI` will be processed by the `MockServer`.

Finally, we add a message toast to indicate for the user that the app runs with mock data.

This approach is perfect for local and automated testing, even without any network connection. Your development does not depend on the availability of a remote server, i.e. to run your tests independently from the back-end service. You can control the mocked data so the requests will return reliable and predictable results.

If the real service connection cannot be established, for example, when there is no network connection, you can always fall back to the local test page and run the app with mock data.

Just run the app now again with the `mockServer.html` file.. The list should now be populated with meet-ups from our mock data. You can also choose the button and see data.

Mock Server [page 1222]
API Reference: `sap.ui.core.util.MockServer`

Step 3: Handling Custom URL Parameters

In this step, we add the functionality to interpret URL parameters in our local mock server configuration.

We know that the OData provider of this service implements a URL parameter that returns only the first three entries of a set. So, for example, calling the URL with parameter `/Meetups?first=3` should return only the first 3 meet-up entries instead of all available entries.

Preview

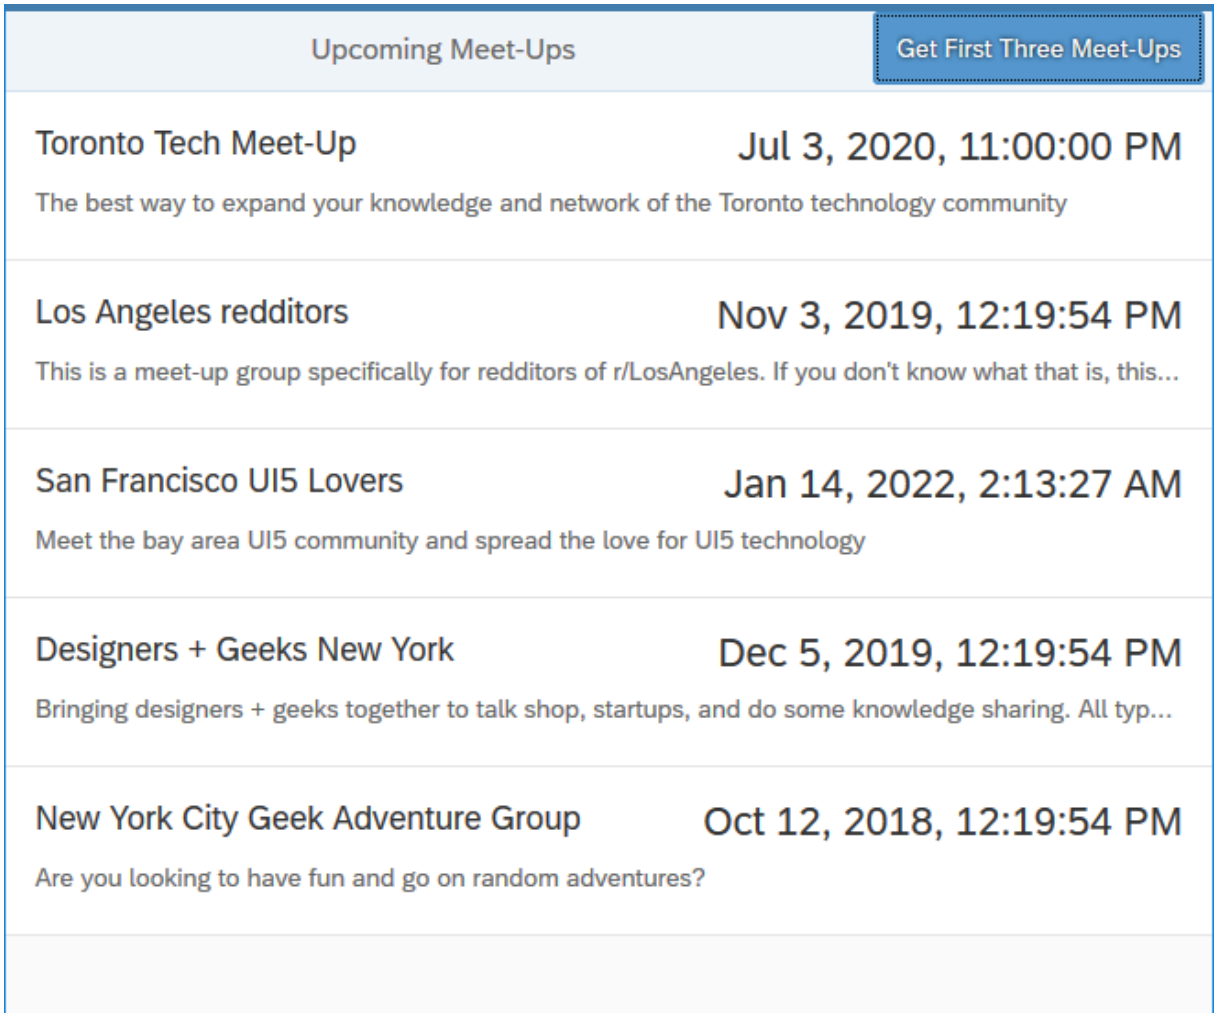

Figure 131: Only the next three meet-ups are shown

Coding

You can view and download all files in the Demo Kit at Mock Server - Step 3.

webapp/localService/mockserver.js

```
sap.ui.define([
    "sap/ui/core/util/MockServer",
    "sap/base/Log"
], function(MockServer, Log) {
    "use strict";
    return {
        /**
         * Initializes the mock server.
         * You can configure the delay with the URL parameter "serverDelay".
```

```
         * The local mock data in this folder is returned instead of the real
data for testing.
         * @public
         */
        init: function() {
            // create
            var oMockServer = new MockServer({
                rootUri: "/"
            });
            oMockServer.simulate("../localService/metadata.xml", {
                sMockdataBaseUrl: "../localService/mockdata",
                bGenerateMissingMockData: true
            });
            // handling custom URL parameter step
            var fnCustom = function(oEvent) {
                var oXhr = oEvent.getParameter("oXhr");
                if (oXhr && oXhr.url.indexOf("first") > -1) {
                    oEvent.getParameter("oFilteredData").results.splice(3, 100);
                }
            };
            oMockServer.attachAfter("GET", fnCustom, "Meetups");
            // start
            oMockServer.start();
            Log.info("Running the app with mock data");
        }
    };
});
```

In some scenarios, a server-specific implementation is used to calculate the returned data. For example, you can use a custom URL parameter that is typically interpreted by the server. The mock server ignores it, thus still returning the entire set of meet-ups.

In this tutorial, we use the URL parameter `first=3` to fetch the first three entries. So, for example, calling to `/Meetups?first=3` should return at most three meet-up entries.

However, since this is a custom parameter that is not part of the standard official OData query options, it will not get processed correctly by the mock server. Moreover, the mock server simply ignores it and return the entire set of meet-ups.

We now enable the functionality when running in mock mode. As its functionality corresponds to the OData `$top` system query, we simply evaluate it to `$top` at runtime.

First, we create a callback function that we later attach to every `GET` request made to the `Meetups` entity set of the service. Note that we choose the `attachAfter` event that is fired after the built-in request processing of the mock server. The event contains the actual `XHR` object and the mock data to be returned to the application. Inside the callback function we remove all results starting from third entry: The `oFilteredData` parameter comes with the event `attachAfter` and contains the mock data entries that are about to be returned in the response.

Second, we attach the callback to every `GET` request to the specific `Meetups` entity set.

Step 4: Calling a Function Import

We only want to display the upcoming meetings and hide the meetings happened in the past in our app. By using a function import that calculates these items on the back end we do not need to do the calculation on the client. The mock server will be instructed to do the calculation locally for testing purposes.

Preview

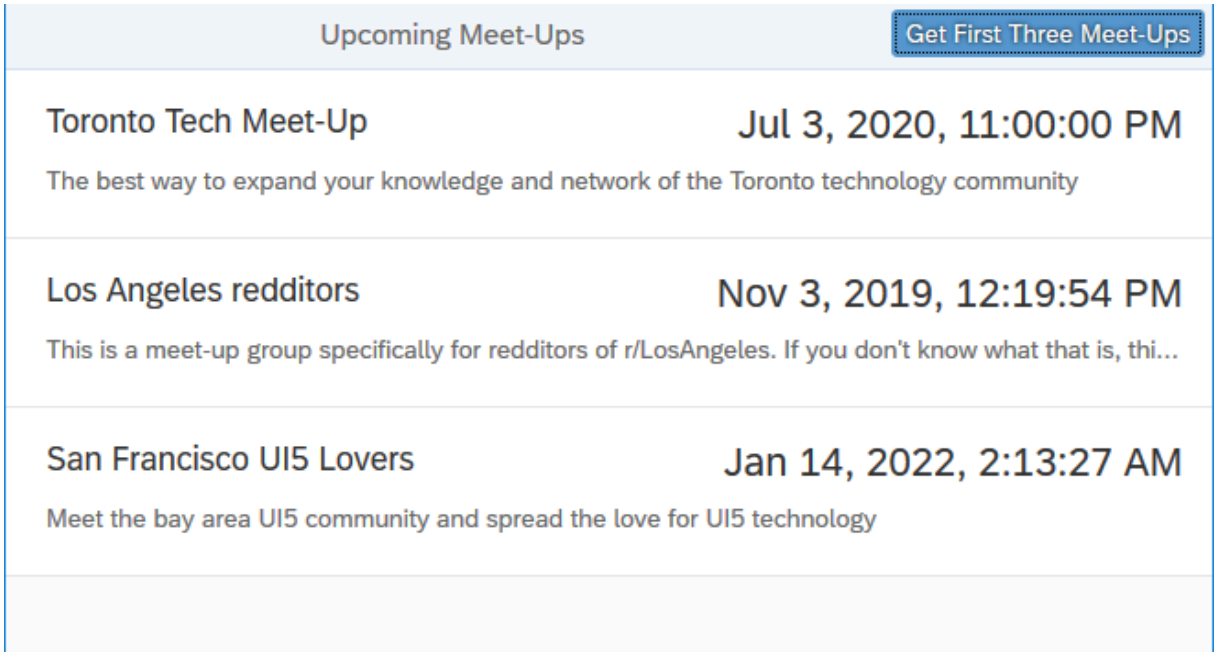

Figure 132: Only the upcoming meet-ups are shown

Coding

You can view and download all files in the Demo Kit at Mock Server - Step 4.

webapp/localService/metadata.xml

```
...
      <EntityContainer Name="NerdMeetups" m:IsDefaultEntityContainer="true">
        <EntitySet Name="Meetups" EntityType="NerdMeetup.Models.Meetup" />
        <FunctionImport Name="FindUpcomingMeetups" EntitySet="Meetups"
ReturnType="Collection(NerdMeetup.Models.Meetup)" m:HttpMethod="GET" />
      </EntityContainer>
    </Schema>
  </edmx:DataServices>
</edmx:Edmx>
```

The function import we are going to use is declared in the `metadata.xml` file.

webapp/view/App.view.xml

```
...
  //Delete items="{/Meetups}"
    <List id="list" items="{/FindUpcomingMeetups}"
noDataText="{i18n>noDataText}">
...
```

We change the binding of the list to a function import call that returns only upcoming meet-ups, instead of the call to the entire meet-ups collection.

After saving and running the app again, we should get the following result:

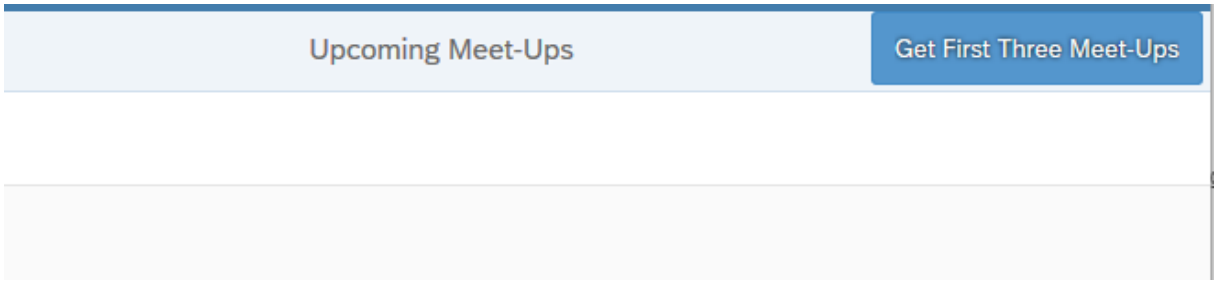

Figure 133: No data visible

Since the function import call is not simulated automatically by the mock server, we do not see any data in list, and a failed network call is issued in the developer tools of the browser.

> → Tip
>
> In Google Chrome, mocked requests will appear in a debug level log of the console (both request and response) and not on the *Network* tab. If you do see them in the *Network* tab, they are not mocked and you need to check your code.

In order to simulate the function import call, we write our own (mocked) implementation, and add to the internal list of requests.

webapp/localService/mockserver.js

```
sap.ui.define([
    "sap/ui/thirdparty/jquery",
    "sap/ui/core/util/MockServer",
    "sap/base/Log"
], function(jQuery, MockServer, Log) {
    "use strict";
    return {
        /**
         * Initializes the mock server.
         * You can configure the delay with the URL parameter "serverDelay".
         * The local mock data in this folder is returned instead of the real
data for testing.
         * @public
         */
        init: function() {
            // create
```

```
            var oMockServer = new MockServer({
                rootUri: "/"
            });
            oMockServer.simulate("../localService/metadata.xml", {
                sMockdataBaseUrl: "../localService/mockdata",
                bGenerateMissingMockData: true
            });
            // handling mocking a function import call step
            var aRequests = oMockServer.getRequests();
            aRequests.push({
                method: "GET",
                path: new RegExp("FindUpcomingMeetups(.*)"),
                response: function(oXhr) {
                    Log.debug("Incoming request for FindUpcomingMeetups");
                    var today = new Date();
                    today.setHours(0); // or today.toUTCString(0) due to
timezone differences
                    today.setMinutes(0);
                    today.setSeconds(0);
                    jQuery.ajax({
                        url: "/Meetups?$filter=EventDate ge " + "/Date(" +
today.getTime() + ")/",
                        dataType : 'json',
                        async: false,
                        success : function(oData) {
                            oXhr.respondJSON(200, {}, JSON.stringify(oData));
                        }
                    });
                    return true;
                }
            });
            oMockServer.setRequests(aRequests);
            // handling custom URL parameter step
            var fnCustom = function(oEvent) {
                var oXhr = oEvent.getParameter("oXhr");
                if (oXhr && oXhr.url.indexOf("first") > -1) {
                    oEvent.getParameter("oFilteredData").results.splice(3, 100);
                }
            };
            oMockServer.attachAfter("GET", fnCustom, "Meetups");
            // start
            oMockServer.start();
            Log.info("Running the app with mock data");
        }
    };
});
```

We push a new request handler to mock the function import call as follows:

1. Fetch the array of requests from the `MockServer`. The mock server holds an internal list of requests that you have to get and set if you want to modify.
2. Push a new request handler to handle the function import
3. Set the updated request array

The request handler has the following structure:

- `method`: The HTTP method of the mock request
- `path`: The relative path (appended to the `rootUri`) of the request.
  We can define the path as a regular expression, for example, to handle URL parameters.
- `response`: A response function that simulates the answer from the server

The `response` function executes a request to the `Meetups` entity set with an OData `$filter` query that actually returns all meet-ups with `EventDate` that is greater than or equals today. We compose a date for the filter and send it to the `server` manually as a synchronous request.

It is o.k. to use `jQuery.sap.sjax` here, because the call will not actually leave the client. It triggers a new request that again is intercepted and processed by the mock server.

We finally respond on the XHR object by calling the `respondJSON` API. It will add the proper content type header for the JSON format and send the result. We provide the HTTP status code `200` (success) and the 'stringified' response data as the arguments. Returning `true` at the end of the function indicates that we have completed the processing of the request in this handler (no additional request handlers should be checked for that request).

When you now start the app again you will see a list of upcoming meet-ups.

Creating and Editing Mock Data in SAP Web IDE (Optional)

webapp/localService/mockserver.js

```
...
oMockServer.simulate("localService/metadata.xml", {
    sMockdataBaseUrl : "localService/mockdata",
    bGenerateMissingMockData : true
});
...
```

The path we gave in the simulate function for mock data is where we want to store the .json file(s).

- Save it (in JSON format) from a real service
- Create it manually
- Generate it in SAP Web IDE by choosing *Edit Mock Data* in the context menu of the `medatdata.xml` file. For more information about SAP Web IDE, see the documentation for SAP Web IDE on the SAP Help Portal at https://help.sap.com/viewer/p/SAP_Web_IDE.

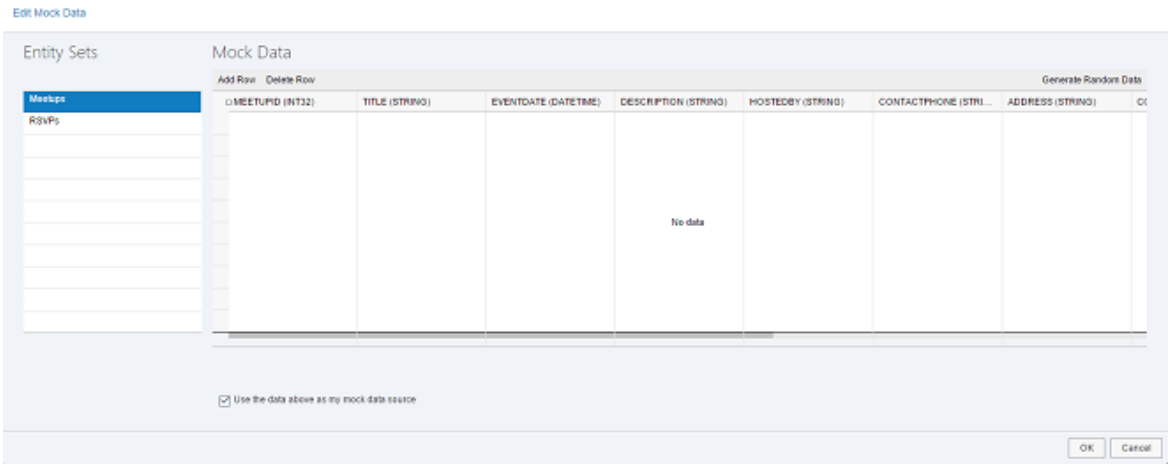

Figure 134: Editing mock data in SAP Web IDE

Worklist App

In this tutorial we will build an app using SAPUI5 that, for example, a shop owner can use to manage his product stock levels.

The app provides the following features:

- Overview of all products
- Track products with shortages or products that are completely out of stock
- Reorder products that are low in stock
- View product details and add comments

We will use the worklist template as a starting point for this tutorial and add additional features to the app as we go through the steps. The template implements a typical "Worklist" floorplan, one of the patterns that are specified by the SAP Fiori design guidelines, but you can also use it as a starting point for easily creating any kind of list-based apps. For more information about worklist floorplans, see the *Related Information* section at the bottom of this topic.

Preview

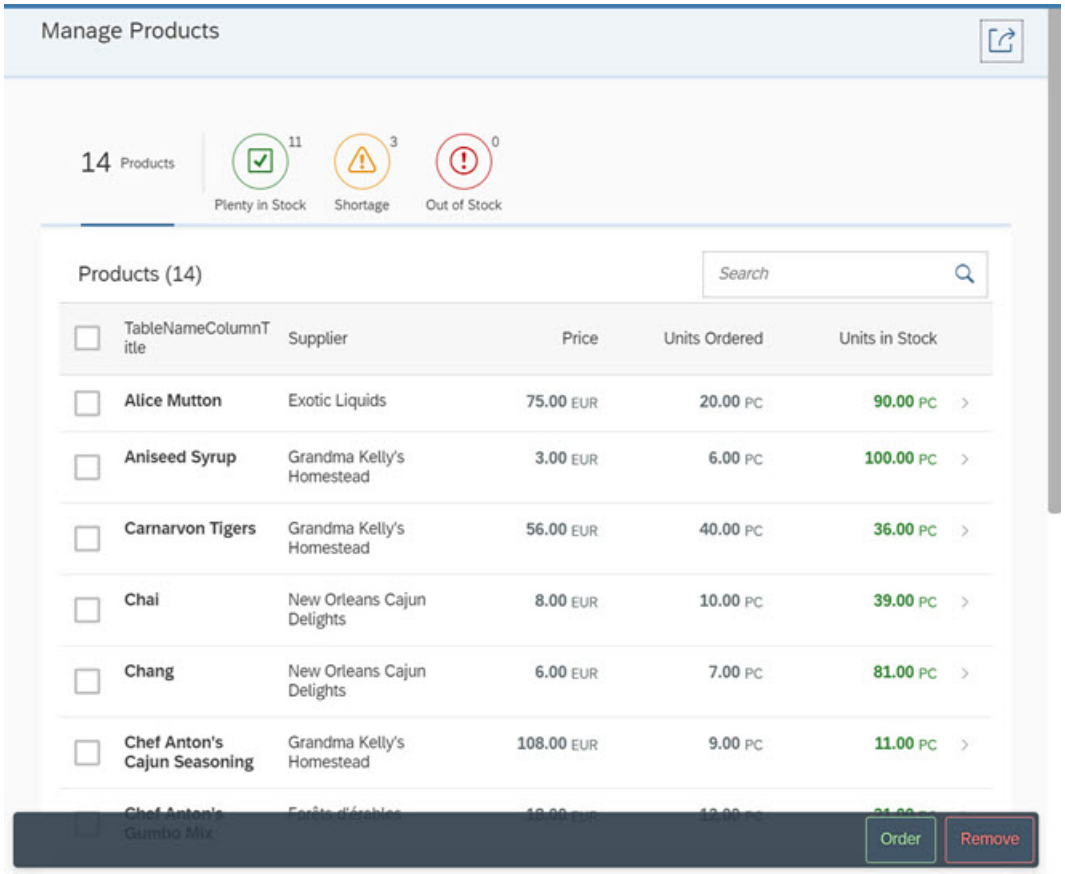

Figure 135: Start page of the app with list of products and actions

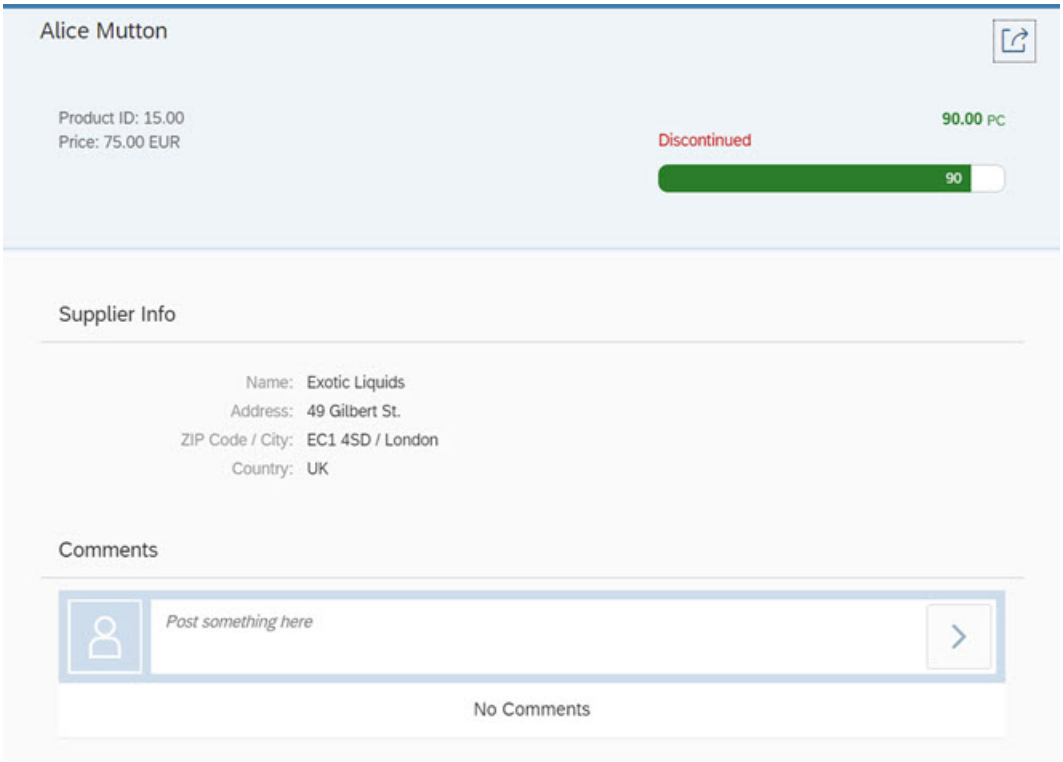

Figure 136: Product detail page of the app

Choose your development environment

You can do this tutorial either with SAP Web IDE or choose your own development environment:

- If you use SAP Web IDE, you don't need to set up a development environment, a server and so on. All you need is a browser and an account for the SAP Cloud Platform. If you don't have an account yet, you can easily get a trial account. We recommend to continue with the SAP Web IDE as it has out-of-the-box support for SAPUI5 and because there is no setup overhead at all.
  In this case, you start with the template that is available in SAP Web IDE as described in option 1 for step 1 of this tutorial (see Step 1 (Option 1): Creating the Initial App with an App Template in SAP Web IDE [page 449]).
- If you want to use your local development environment and deploy to any Web server of your choice, you download the code for step 1 from the Demo Kit at Worklist App. In this case, start with option 2 for step 1 of this tutorial (see Step 1 (Option 2): Downloading the Code [page 454]).

There might be some small differences between the worklist app code generated by the SAP Web IDE template and the code downloaded from the Demo Kit. However, the differences are small and not relevant for the purpose of this tutorial

> → Tip
>
> You don't have to do all tutorial steps sequentially, you can also jump directly to any step you want. Just download the code from the previous step, copy it to your workspace and make sure that the application runs by calling the `webapp/test.html` file.
>
> For more information check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]

SAP Fiori design guidelines: Worklist Floorplans
Worklist Template [page 1400]
Get a SAP Cloud Platform trial account

Step 1 (Option 1): Creating the Initial App with an App Template in SAP Web IDE

This first step is only relevant if you decided to use the SAP Web IDE. In this step, we will set up the worklist app using a template and configure the service to display products in the app. The template includes generic app functionality and tests that can be easily extended with custom functionality for our use case.

Prerequisites

Set up your SAP Web IDE and define a destination to the Northwind OData service as described under App Development Using SAP Web IDE [page 44].

Preview

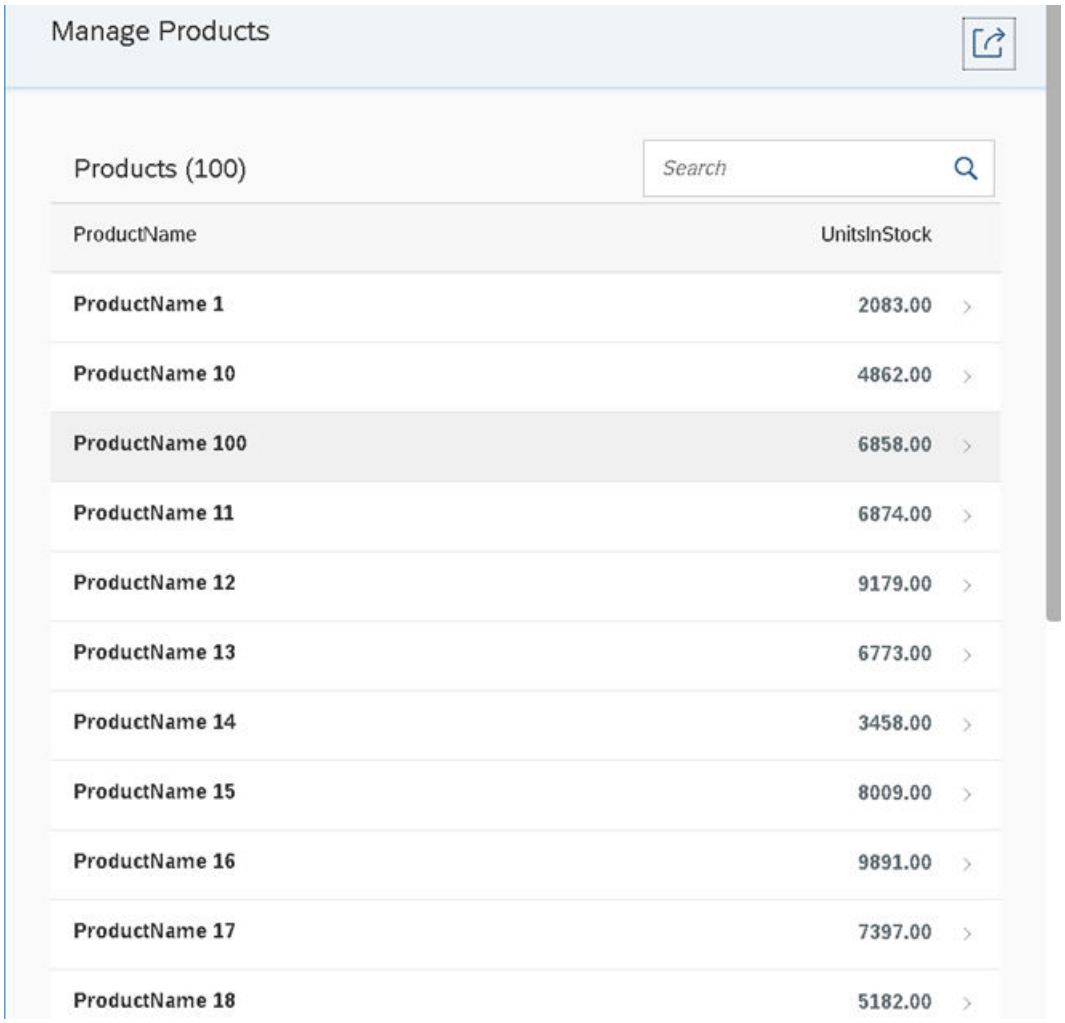

Figure 137: The worklist app

Create the Initial App Using the Template Wizard

1. Launch SAP Web IDE.
2. Choose *File* > *New* > *Project from Template*
3. Select the *SAP Fiori Worklist Application* template, and choose the latest SAPUI5 version from the *SAPUI5 Version* dropdown box. Choose *Next*.
4. On the *Basic Information* screen, enter `MyWorklistApp` as project name. Enter the following data:

Table 7: *App Descriptor Data*

Field	Value	Description
Title	`Manage Products`	Title of the app, which will be displayed as header.

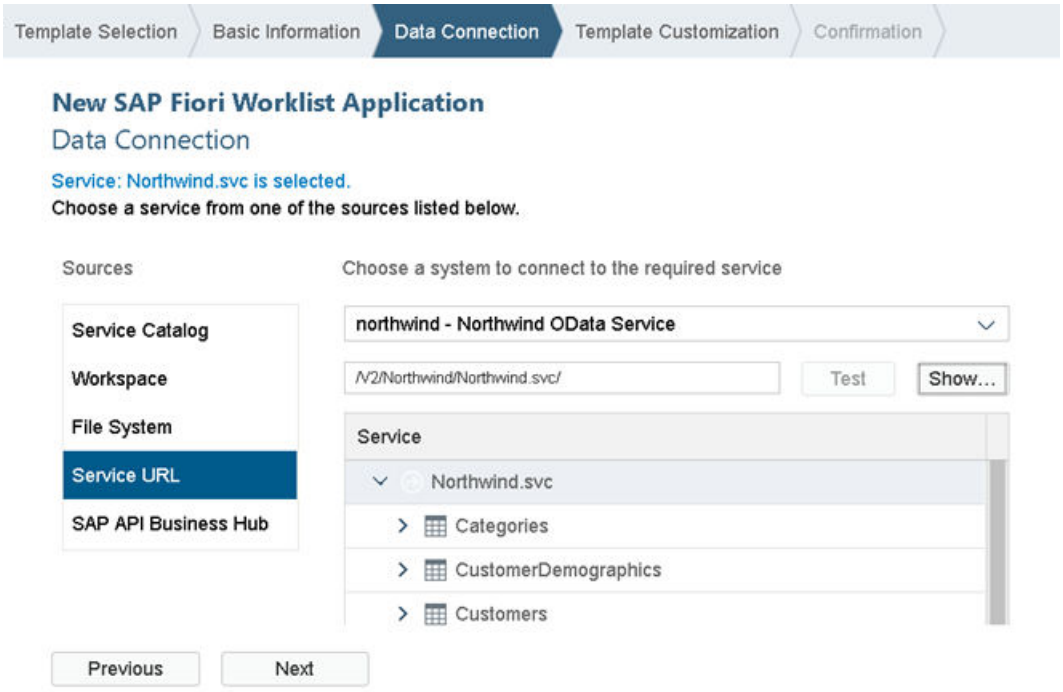
Field	Value	Description
Namespace	`mycompany.myapp`	The application namespace is a unique identifier for your application resources.
Description	`My Worklist App`	Short description of your app.

Choose *Next*.

5. On the *Data Connection* screen, select *Service URL* in the *Sources* area.
Choose *northwind - Northwind OData Service* and enter the URL `/V2/Northwind/Northwind.svc/`.

> **i Note**
>
> If you cannot find the Northwind service, create the destination as described under Create a Northwind Destination [page 49].

Validate the URL by choosing *Test* next to the URL. You should now see the service entities as displayed in the following screenshot:



> **i Note**
>
> At runtime, the relative URL `/V2/Northwind/Northwind.svc/` is prefixed with `/destinations/northwind`. As a result, all our Northwind OData requests will be proxied via the *Northwind OData Service* destination that is defined in the SAP Cloud Platform Cockpit. The destination contains the URL to the resource `http://services.odata.org` and has the proxy type *Internet*. From this configuration the proxy knows where the requests are directed.

Choose *Next*.

6. On the *Template Customization* screen, select the following data:

Table 8: *Application Scenario*

Field	Value	Description
App Type	**`Standalone App`**	We create a standalone app that can be run without SAP Fiori launchpad (FLP). If you choose to build an *SAP Fiori Launchpad Component*, you automatically get test HTML files with the FLP Sandbox, and the app automatically includes additional features like *Save as Tile*.

Table 9: *Data Binding - Object*

Field	Value	Description
Object Collection	**`Products`**	This is the main entity set that will be displayed in the app. Some of the other fields below are automatically selected depending on this field.
Object Collection ID	**`ProductID`**	The unique key that is used to identify the object collection.
Object Title	**`ProductName`**	The display name of the main entity.
Object Numeric Attribute	**`UnitsInStock`**	The number displayed next to the product name. In this scenario we pick the `UnitsInStock`. This represents the stock quantity of the product.

7. Choose *Next* and *Finish*

A new folder `MyWorklistApp` is now available in your local workspace. It contains the following files and folders of the initial app:

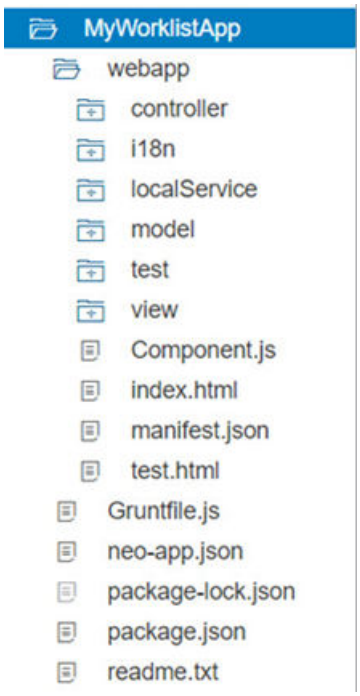


Figure 138: Folder structure of the initial project

> **i Note**
>
> The auto-generated files `Gruntfile.js`, `package-lock.json`, and `package.json` are only necessary for working with SAP Web IDE or a local IDE. They are not included in case you download the example code from the *Samples*.
>
> These three files will not be changed throughout this tutorial, so we will ignore them in the following steps.

8. Run the app.
   There are several HTML files available in the `webapp/test` folder, which enable you to run the app with a Mock Server. You can also use them to run unit tests and OPA tests.

   > **i Note**
   >
   > The template comes with two run configurations for SAP Web IDE: You can either run the app with data from a real back end service (*Run webapp/index.html*) or with local mock data (*Run webapp/test/mockServer.html (Mock Server)*).
   >
   > We choose the mock server option, because then the app will still be able to run even if the back end is unavailable or the service is not implemented yet. We could even configure a delay to make local testing more realistic.

   You should see the screen, which contains generated mock data.

From now on you can quickly run the app by selecting the root folder `MyWorklistApp` of your project in SAP Web IDE and pressing the *Run* button. The system will automatically use the option from the *Run* menu that you chose last (in this case, the *Run with MockServer* option).

> **i Note**
>
> The texts in the `i18n.properties` file are automatically generated based on the template Customizing (OData entity set, entities, properties, and texts). The result can be incorrect texts like "Enter an <Products> name or a part of it." You should therefore revise the generated texts in the `i18n.properties` file.

Related Information

App Development Using SAP Web IDE [page 44]

Step 1 (Option 2): Downloading the Code

In this step, we set up the initial app without SAP Web IDE.

If you are working with another IDE or development environment than the SAP Web IDE, you can simply download the code from the *Samples* in the Demo Kit at Worklist App - Step 1 and skip the wizard steps described in the previous step of this tutorial. The code contains a preconfigured application project that can be used as a starting point to develop the worklist app. You can deploy the downloaded application to a (local) Web server and call the `webapp/test/mockServer.html` file in your browser manually to start the app.

To access the real service, you would need to set up a proxy service that connects your app project deployed on a Web server to the remote service. Due to the so called same-origin policy browsers deny AJAX requests to service endpoints in case the domain/subdomain, protocol, or port differ from the app's domain/subdomain, protocol, or port. Cross-origin resource sharing (CORS) makes it possible to break out of these restrictions derived from the same-origin policy. With CORS the server and browser agree which cross-origin requests are allowed. Another way to bypass the same-origin policy is using a proxy on the same host of the app. To keep it simple, our app contains a test page to run the app with local mock data instead of retrieving the data from a real server hosted somewhere else. This way we won't have any issues related to the same-origin policy of the browsers, as long as we run the app with our mock server.

> **i Note**
>
> The texts in the `i18n.properties` file are automatically generated based on the template Customizing (OData entity set, entities, properties, and texts). The result can be incorrect texts like "Enter an <Products> name or a part of it." You should therefore revise the generated texts in the `i18n.properties` file.

Related Information

Development Environment [page 41]

Step 1 (Result): The Initial App

With the generated code (SAP Web IDE) or the downloaded code from the Demo Kit, you have an initial app structure with the following content inside the `webapp` folder.

- **Home Page** (`webapp/view/Worklist.view.xml` file)
  The home page of the app shows a table of products including the corresponding number of units in the stock. The title of the table shows how many items are available. A search field in the header toolbar of the table allows you to search for a product by name. Pressing a table row navigates the user to a new page that shows the details of the pressed product.
- **Data**
  You can run the app with the real service or with the mock server serving mock data. In the `webapp/localService/mockserver.js` file, the mock server is configured. Using the mock server in this tutorial allows us to easily run the code even without network connection and without the need of having a remote server for our application data. To run the app with the mock server and its corresponding mock data the `/webapp/test/mockServer.html` file has to be called in the browser.
  The `webapp/localService/metadata.xml` file is used by the mock server to describe our OData service. In this step, the mock server will generate mock data based on this file. In a subsequent step the mock server will use our own custom mock data.
- **Configuration of the App**
  In the `webapp/manifest.json` descriptor file, we configure our app. The descriptor file contains the following relevant sections:
  - `sap.app`
    In this section we reference an `i18n.properties` file and use a special syntax to bind the texts for the title and description properties. In the `dataSources` section, we tell our app where to find our `mainService` OData service. As you might guess, the URI correlates to the `rootUri` of our mock server instance, which can be found in `webapp/localService/mockserver.js`. It is important that these two paths match to allow our mock server to provide the test data we defined above.
  - `sap.ui5`
    In the `sap.ui5` section, we declare with the `rootView` parameter that our `mycompany.myapp.MyWorklistApp.view.App` view shall be loaded and used as the `rootView` for our app.
    Furthermore, we define two models to be automatically instantiated and bound to the component: an `i18n` model and a default model `""`. The latter references our `mainService dataSource`, which is declared in our `sap.app` section as an OData 2.0 data source. The `i18n` file can be found at `webapp/i18n/i18n.properties`. The `mainService` data source will be mocked by our mock server.

> **i Note**
>
> There is a `test.html` file in the `webapp` folder. This file serves as an easy entry point for developers to run and test the app in various ways during development. It contains links to the relevant files inside the `test` folder, which you can use to run with the Mock Server or to run unit tests and OPA tests.

Folder Structure: Where to Put Your Files [page 1428]

Step 2: Custom Mock Data

In this step, we want to change the mock data of the initial app. The service metadata only contains a description of the service entities. The mock server that is part of the app will auto-generate random mock data based on the data types defined in the metadata file. To have a more realistic development environment we will now add additional sample data.

Preview

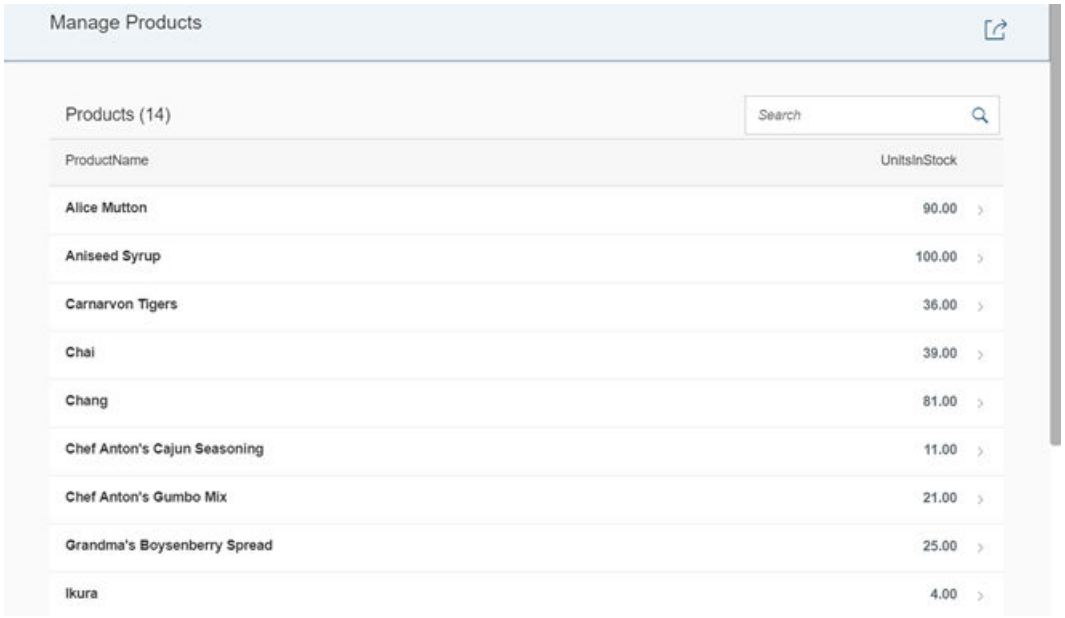

Figure 139: The product list of the initial app with custom mock data

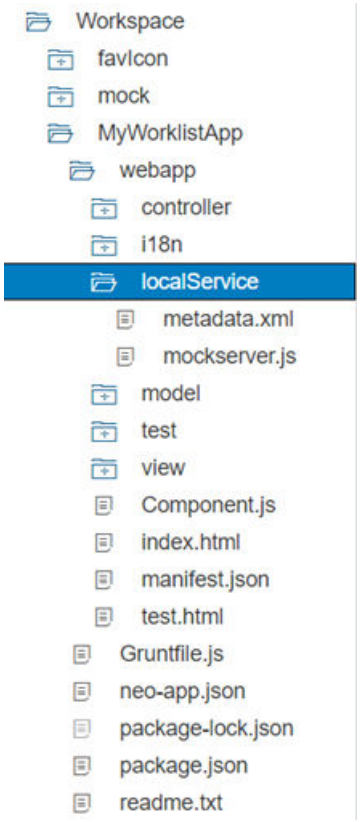

Figure 140: Folder structure for this step including custom mock data

The `webapp/localService/metadata.xml` file used by the mock server describes our OData service. The service only has two OData entities, and the data for these two entities is located in the folder `webapp/localService/mockdata`:

- Products
  A product has typical properties like `ProductName` and `UnitsInStock` as well as a navigation property to a supplier entity referenced by a `SupplierID`. Of course, the entity has an ID property `ProductID`. The corresponding `EntitySet` is `Products`. The actual test data containing several products is located in the `webapp/localService/mockdata/Products.json` file.
- Suppliers
  Later in this tutorial, we will display some information about the supplier of a product. The properties are `CompanyName`, `Address`, `City`, `PostalCode`, `Country`, and so on; all of them contain textual information of type `Edm.String`. The entity has an ID property `SupplierID` and the corresponding `EntitySet` is `Suppliers`. The supplier data for products is located in the file `webapp/localService/mockdata/Suppliers.json`.

Coding

You can view and download all files in the *Samples* in the Demo Kit at Worklist App - Step 2.

      }
    }
  },
  {
    "ProductID": 15,
    "ProductName": "Alice Mutton",
    "UnitsInStock": 90,
    "UnitsOnOrder": 20,
    "UnitPrice": 75,
    "SupplierID": 2,
    "Discontinued": true,
    "Supplier": {
      "__deferred": {
```

```
        "uri": "/destinations/northwind/V2/Northwind/Northwind.svc/Products(15)/
Supplier"
      }
    }
  }
]
```

First create a new `mockdata` folder inside `webapp/localService`. Create a `Products.json` file, and copy and paste the code.

webapp/localService/mockdata/Suppliers.json (New)

```
[
  {
    "SupplierID": 1,
    "CompanyName": "New Orleans Cajun Delights",
    "ContactName": "Shelley Burke",
    "ContactTitle": "Order Administrator",
    "Address": "P.O. Box 78934",
    "City": "New Orleans",
    "Region": "LA",
    "PostalCode": "70117",
    "Country": "USA"
  },
  {
    "SupplierID": 2,
    "CompanyName": "Exotic Liquids",
    "ContactName": "Charlotte Cooper",
    "ContactTitle": "Purchasing Manager",
    "Address": "49 Gilbert St.",
    "City": "London",
    "Region": "UK",
    "PostalCode": "EC1 4SD",
    "Country": "UK"
  },
  {
    "SupplierID": 3,
    "CompanyName": "Grandma Kelly's Homestead",
    "ContactName": "Regina Murphy",
    "ContactTitle": "Sales Representative",
    "Address": "707 Oxford Rd.",
    "City": "Ann Arbor",
    "Region": "MI",
    "PostalCode": "48104",
    "Country": "USA"
  },
  {
    "SupplierID": 4,
    "CompanyName": "Forêts d'érables",
    "ContactName": "Chantal Goulet",
    "ContactTitle": "Accounting Manager",
    "Address": "148 rue Chasseur",
    "City": "Ste-Hyacinthe",
    "Region": "Québec",
    "PostalCode": "J2S 7S8",
    "Country": "Canada"
  },
  {
    "SupplierID": 5,
    "CompanyName": "Plutzer Lebensmittelgroßmärkte AG",
    "ContactName": "Martin Bein",
    "ContactTitle": "International Marketing Mgr.",
    "Address": "Bogenallee 51",
    "City": "Frankfurt",
    "Region": "DE",
    "PostalCode": "60439",
    "Country": "Germany"
```

```
  },
  {
    "SupplierID": 6,
    "CompanyName": "Lyngbysild",
    "ContactName": "Niels Petersen",
    "ContactTitle": "Sales Manager",
    "Address": "Lyngbysild Fiskebakken 10",
    "City": "Lyngby",
    "Region": "NL",
    "PostalCode": "2800",
    "Country": "Denmark"
  },
  {
    "SupplierID": 7,
    "CompanyName": "Formaggi Fortini s.r.l.",
    "ContactName": "Elio Rossi",
    "ContactTitle": "Sales Representative",
    "Address": "Viale Dante, 75",
    "City": "Ravenna",
    "Region": "IL",
    "PostalCode": "48100",
    "Country": "Italy"
  }
]
```

Create a `Suppliers.json` file, and copy and paste the code.

You can now run the app again and see the mock data in your app.

> **i Note**
>
> In order to get realistic mock data you can call a real OData service directly in your browser to receive the real data of a given `Entity` or `EntitySet`. Make sure that you call the service with the system option `$format=json`, that is `http://services.odata.org/V2/Northwind/Northwind.svc/Products?$format=json`. This will return the data in JSON format, which is the format required for our mock data. This data is put into a local file in your application's `webapp/localService/mockdata` folder. The file name is expected to be the name of the corresponding `EntitySet` ends with `.json`, for example `Products.json`. The obtained data from the OData service can serve as a first set of mock data, which you can change to your needs if necessary. SAP Web IDE also offers a dedicated editor for mock data that makes the maintenance of the data even easier.

Step 3: Extending the Worklist Table

In this step, we will edit the worklist table to include additional columns for our manage product stocks scenario. We display the supplier, the product price, and the number of units on order for each product and format the values accordingly.

Preview

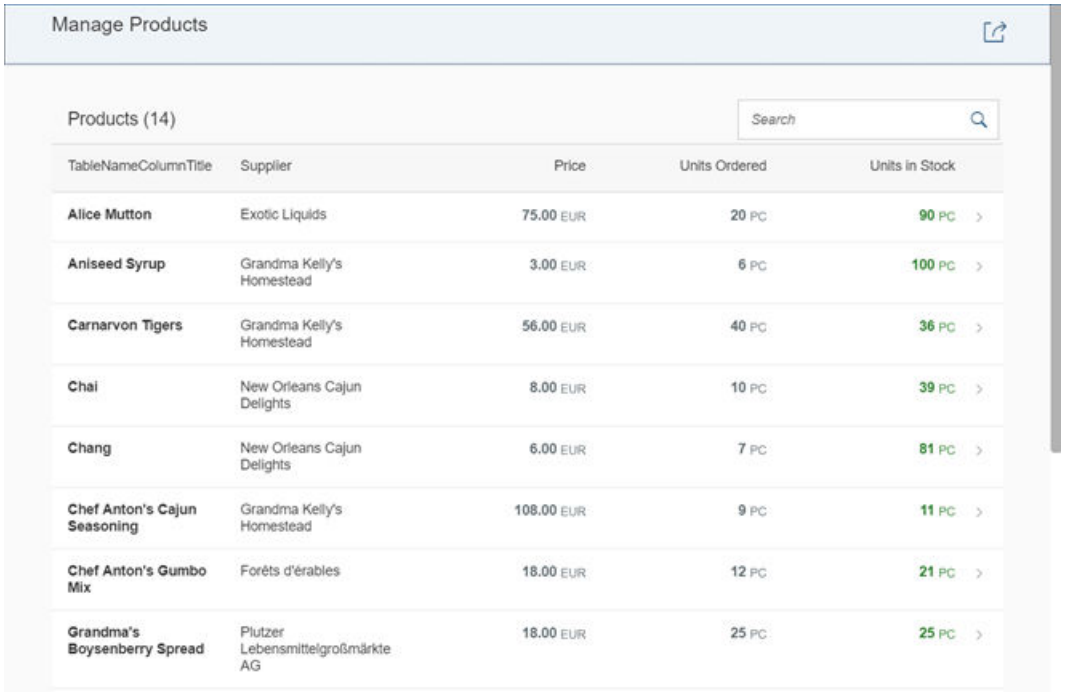

Figure 141: The improved worklist table with new columns and formatting

Coding

You can view and download all files in the Demo Kit at Worklist App - Step 3.

webapp/view/Worklist.view.xml

```
…
<Table
    id="table"
    width="auto"
    items="{
        path: '/Products',
        sorter: {
            path: 'ProductName',
            descending: false
        },
        parameters: {
            'expand': 'Supplier'
        }
    }"
```

```
    noDataText="{worklistView>/tableNoDataText}"
    busyIndicatorDelay="{worklistView>/tableBusyDelay}"
    growing="true"
    growingScrollToLoad="true"
    updateFinished=".onUpdateFinished">
    <headerToolbar>
        <Toolbar>
            <Title id="tableHeader" text="{worklistView>/worklistTableTitle}"/>
            <ToolbarSpacer />
            <SearchField
                id="searchField"
                tooltip="{i18n>worklistSearchTooltip}"
                search=".onSearch"
                width="auto">
            </SearchField>
        </Toolbar>
…
```

We want to display the supplier's company name in a separate column in the table for each product. Therefore, we extend the `items` aggregation of the table with an `expand` parameter for the `Supplier` entity. With this, the supplier data will be already included in the service request for the products.

We expand the supplier because we want to avoid sending one additional request for each product to get the supplier. Furthermore, this allows us to bind directly to `{Supplier/CompanyName}` later.

> **i** Note
>
> **OData's "expand" Mechanism:**
>
> OData `$expand` is very helpful when combining data from different service entities. Instead of having to send an additional service request for the second entity, we simply expand the service call to include the second entity as well – similar to a join in a relational database. Have a look at the local service metadata definition file `webapp/localService/metadata.xml` that represents the interface of our service. In the `metadata` you can see a list of entities that are available in this service, for example `Products` and `Suppliers`. Each entity lists a number of fields that we can bind to the properties of our view.

webapp/localService/metadata.xml

```
<EntityType Name="Product">
    <Key>
        <PropertyRef Name="ProductID"/>
    </Key>
    <Property
        xmlns:p8="http://schemas.microsoft.com/ado/2009/02/edm/annotation"
Name="ProductID" Type="Edm.Int32" Nullable="false"
p8:StoreGeneratedPattern="Identity"/>
        <Property Name="ProductName" Type="Edm.String" Nullable="false"
MaxLength="40" Unicode="true" FixedLength="false"/>
        <Property Name="SupplierID" Type="Edm.Int32" Nullable="true"/>
        <Property Name="CategoryID" Type="Edm.Int32" Nullable="true"/>
        <Property Name="QuantityPerUnit" Type="Edm.String" Nullable="true"
MaxLength="20" Unicode="true" FixedLength="false"/>
        <Property Name="UnitPrice" Type="Edm.Decimal" Nullable="true"
Precision="19" Scale="4"/>
        <Property Name="UnitsInStock" Type="Edm.Int16" Nullable="true"/>
        <Property Name="UnitsOnOrder" Type="Edm.Int16" Nullable="true"/>
        <Property Name="ReorderLevel" Type="Edm.Int16" Nullable="true"/>
        <Property Name="Discontinued" Type="Edm.Boolean" Nullable="false"/>
        <NavigationProperty Name="Category"
Relationship="NorthwindModel.FK_Products_Categories" FromRole="Products"
ToRole="Categories"/>
```

```
        <NavigationProperty Name="Order_Details"
Relationship="NorthwindModel.FK_Order_Details_Products" FromRole="Products"
ToRole="Order_Details"/>
        <NavigationProperty Name="Supplier"
Relationship="NorthwindModel.FK_Products_Suppliers" FromRole="Products"
ToRole="Suppliers"/>
    </EntityType>
```

In the entity `Products`, you can see that an additional relation to the `Supplier` is available as a `NavigationProperty`. A navigation property links two entities of an OData service and assigns the supplier to the product here.

When using a real OData service, the interface would be available by calling the service URL directly in a browser (e.g. `http://services.odata.org/V3/Northwind/Northwind.svc/$metadata` for the Northwind OData test service). In our app project we use local mock data and serve the data with the mock server instead.

webapp/view/Worklist.view.xml

```
…
<columns>
    <Column id="nameColumn">
        <Text
            id="nameColumnTitle"
            text="{i18n>TableNameColumnTitle}"/>
    </Column>
    <Column
        id="supplierNameColumn"
        demandPopin="false"
        minScreenWidth="Tablet">
        <Text text="{i18n>TableSupplierColumnTitle}"/>
    </Column>
    <Column
        id="unitPriceColumn"
        hAlign="End"
        demandPopin="true"
        minScreenWidth="Tablet">
        <Text text="{i18n>TablePriceColumnTitle}"/>
    </Column>
    <Column
        id="unitsOnOrderColumn"
        demandPopin="true"
        minScreenWidth="Tablet"
        hAlign="End">
        <Text text="{i18n>TableUnitsOrderedColumnTitle}"/>
    </Column>
    <Column
        id="unitsInStockColumn"
        hAlign="End">
        <Text text="{i18n>TableUnitsInStockColumnTitle}"/>
    </Column>
</columns>
…
```

Next, we change the column definitions of the table. We define the new columns and update the existing ones in the columns aggregation of the table according to the code above (i.e. just copy and paste the highlighted content into your columns aggregation).

The column definitions include a text that we will later define in the resource bundle (`i18n` model – a short name for internationalization) so that the column titles can be translated to other languages. And we will define additional settings for text alignment and making the table responsive. Some columns are not as important as others and can be displayed below the main columns (`popin`) on devices with small or medium-sized screens.

Let's have a detailed look at the columns:

- Product Name
  The product name is the first column and it is always visible on any device.
- Supplier
  Each product has a supplier. This column contains the company name of the supplier supplying the product. On small screen devices like smart phones we hide this column as we do not have much screen space for a table.
- Price
  The currency of the product's unit price is Euro (EUR). We are talking about stock levels in this app, so the number of units is most interesting for us - not their price. Price is still good to know, so it is not entirely removed. However, this field is not as important as the unit fields and will `popin` on smart phones.
- Units on Order
  This column shows the units that have been ordered already for this product and will be added to the stock shortly. In other words, this is the number of items ordered, but not yet received. A shortage for a product can easily be resolved by reordering the product in advance (we add this feature later). This field will `popin` on smart phone devices.
- Units in Stock
  The column contains the product's stock units currently available for sale. This field is the most important column for our manage product stocks app. Therefore, this column is visible for all devices and it's visible without a `popin`. Later, we will use this column to visualize a stock status for the specific products so that attention will be drawn to any stock issues with the products.

webapp/model/formatter.js

```
sap.ui.define([
    "sap/ui/core/library"
] , function (coreLibrary) {
    "use strict";
    // shortcut for sap.ui.core.ValueState
    var ValueState = coreLibrary.ValueState;
    return {
        ...
        },

        /**
         * Defines a value state based on the stock level
         *
         * @public
         * @param {number} iValue the stock level of a product
         * @returns {string} sValue the state for the stock level
         */
        quantityState: function(iValue) {
            if (iValue === 0) {
                return ValueState.Error;
            } else if (iValue <= 10) {
                return ValueState.Warning;
            } else {
                return ValueState.Success;
            }
        }
    };
});
```

Our table has a column that will contain the units in stock for each product. It would be nice to visualize the corresponding numbers so that we can point out important information to the users, such as a shortage. We want to visualize the numbers by using a specific `ValueState` depending on the units in stock. This can be achieved by a simple formatter, which we will use later.

We add a new formatter function `quantityState` to the `webapp/model/formatter.js` file. The `ValueState` type is loaded as an additional dependency. The formatter implements the following logic with a simple `if/else` statement:

- A totally depleted stock (0 pieces remaining) will return a semantic `Error` state that will color the text in the units in stock field red.
- Very low stock (10 or less pieces remaining) will lead to a `Warning` state (orange).
- A stock of more than 10 items will convert to `Success` (green)

webapp/view/Worklist.view.xml

```
…
<items>
    <ColumnListItem
        type="Navigation"
        press="onPress">
        <cells>
         <ObjectIdentifier
            title="{ProductName}"/>
         <Text text = "{Supplier/CompanyName}"/>
         <ObjectNumber
            unit="EUR"
            number="{
               path: 'UnitPrice',
               formatter: '.formatter.numberUnit'
            }"/>
         <ObjectNumber
            number="{UnitsOnOrder}"
            unit="PC"/>
         <ObjectNumber
            number="{UnitsInStock}"
            unit="PC"
            state="{
               path: 'UnitsInStock',
               formatter: '.formatter.quantityState'
            }"/>
      </cells>
   </ColumnListItem>
</items>
…
```

The next task is to define the cells to appear in each row of the table. For each column, we define a control in the `cells` aggregation of the table and configure the data binding as well as the formatting of the data.

- The first cell simply displays the `ProductName` property of the corresponding entity by using an `ObjectIdentifier` control.
- The *Supplier* cell of each row is a simple `sap.m.Text` control. Its text property is bound to `Supplier/CompanyName`. This references the property `CompanyName` of the entity's `NavigationProperty Supplier`. This `NavigationProperty` will be expanded automatically; we configured this earlier in this step.
- The *Price* cell uses an `sap.m.ObjectNumber` control and a custom formatter. You can find the formatter's implementation in the `webapp/model/formatter.js` file. The unit property is not bound and hard coded to "EUR" as the currency is not part of the model for our app. The units on order are displayed with a sap.m.ObjectNumber control as well, but without additional formatting. Its `unit` property is hard coded to `PC`, which is the short form for "pieces".
- The last cell shows the units in stock and was already specified in the previous step. We would like to use this field to show an additional status based on the stock level so we change the binding syntax to an object

notation and add an additional formatter `quantityState`. We implemented this formatter in the previous code block above.

> **i Note**
>
> The formatter functions used in this XML view are loaded by the controller and thus can be accessed relatively to the controller through the property name `.formatter`. This logic is already part of the initial app.

webapp/i18n/i18n.properties

```
#XTIT: The title of the column containing Product name
TableProductColumnTitle=Product
#XTIT: The title of the column containing Supplier name
TableSupplierColumnTitle=Supplier

#XTIT: The title of the column containing Price
TablePriceColumnTitle=Price

#XTIT: The title of the column containing Ordered Units
TableUnitsOrderedColumnTitle=Units Ordered

#XTIT: The title of the column containing Units in Stock
TableUnitsInStockColumnTitle=Units in Stock
#XBLI: Text for a table with no data
tableNoDataText=No products are currently available
...
```

Finally, we modify the existing column names in the resource bundle file `webapp/i18n/i18n.properties` to match our scenario and add the new texts for the column titles.

> **i Note**
>
> The `webapp/i18n/i18n.properties` file contains some annotations for each key in the file. These annotations offer some more context, which can help translators to better interpret the semantics of the text belonging to the keys. An example for such an annotation is XTIT in the `i18n.properties` file above, which tells that the corresponding key is supposed to be used as a title. The guidelines at https://github.com/SAP/openui5/blob/master/docs/guidelines/translationfiles.md give you a better idea of how this can be used. Be aware that this is how SAP uses the annotations internally. In case you want to use this approach to work with your own translators make sure that you agree on a common set of allowed annotations that everybody understands.

> **→ Tip**
>
> **Testing the Responsiveness of the App**
>
> In the previous code blocks of this step we made sure that our table is responsive. Depending on the device type columns are hidden, displayed as a popin, or displayed without a popin. Now, we want to test the responsiveness without the having different devices. This can be done in different ways, we will cover two options:
>
> - **Testing the responsiveness with the SAP Web IDE**
>   SAP Web IDE can simulate different screen sizes. You just have to make sure that the run configuration is set up correctly:
>
>   1. In SAP Web IDE, choose *Run* > *New Configuration*

2. Select the *Run with MockServer* configuration.
3. In the *Frame* screen area, select the *Open with frame* checkbox.
   If you create a new project this option is switched on by default. For apps created based on the Worklist template, however, this option is switched off to make it easier to debug the application coding.
4. Save the configuration and close the dialog.

If you now run the application again, you will see the surrounding frame, in which you can easily choose between different screen sizes and change the device orientation.
Switch, for example from *Medium* to *Small*, and you will see that the table behaves as expected.

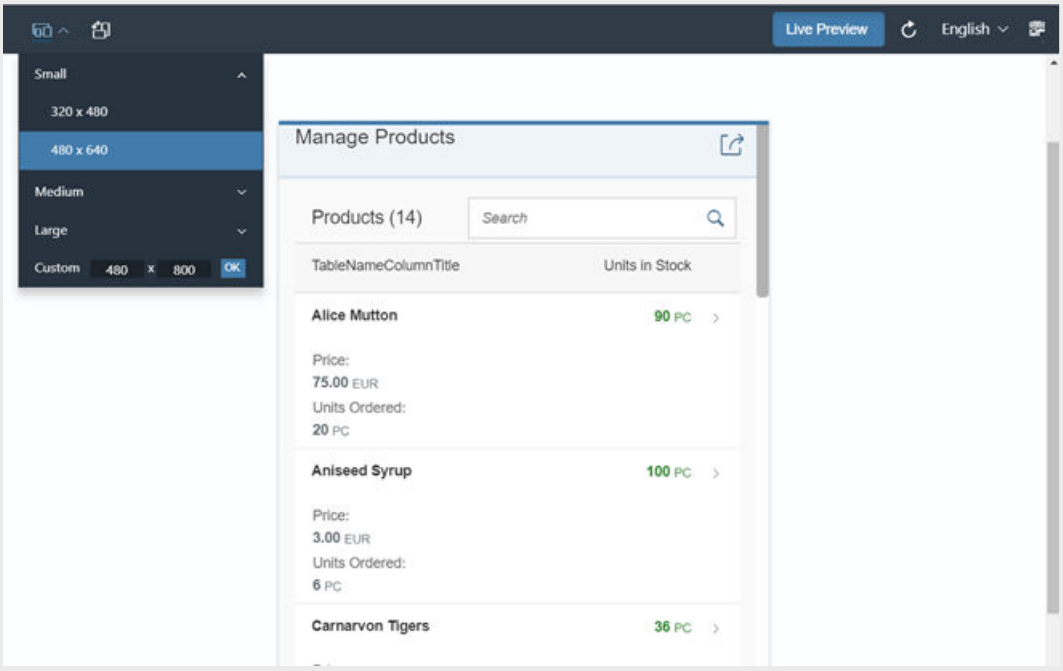

Figure 142: Testing the responsiveness in SAP Web IDE

- **Testing the responsiveness using the Developer Tools of Google Chrome**
  If you use the Google Chrome browser, you can also use its great developer tools to test the responsiveness of your app.
  1. Call the app and open the developer tools in Chrome with `F12`
  2. Choose the *Toggle device mode* icon.
  3. Now choose from the different devices in the *Models* field, and observe the behavior of your app.

Step 4: Quick Filter for the Worklist

For easily detecting and managing product shortages in our app, we will add a quick filter for the worklist table. Users can press the filter tabs to display the products according to whether they are in stock, have low stock or no stock. The table will update accordingly and show only the products matching the criteria.

Preview

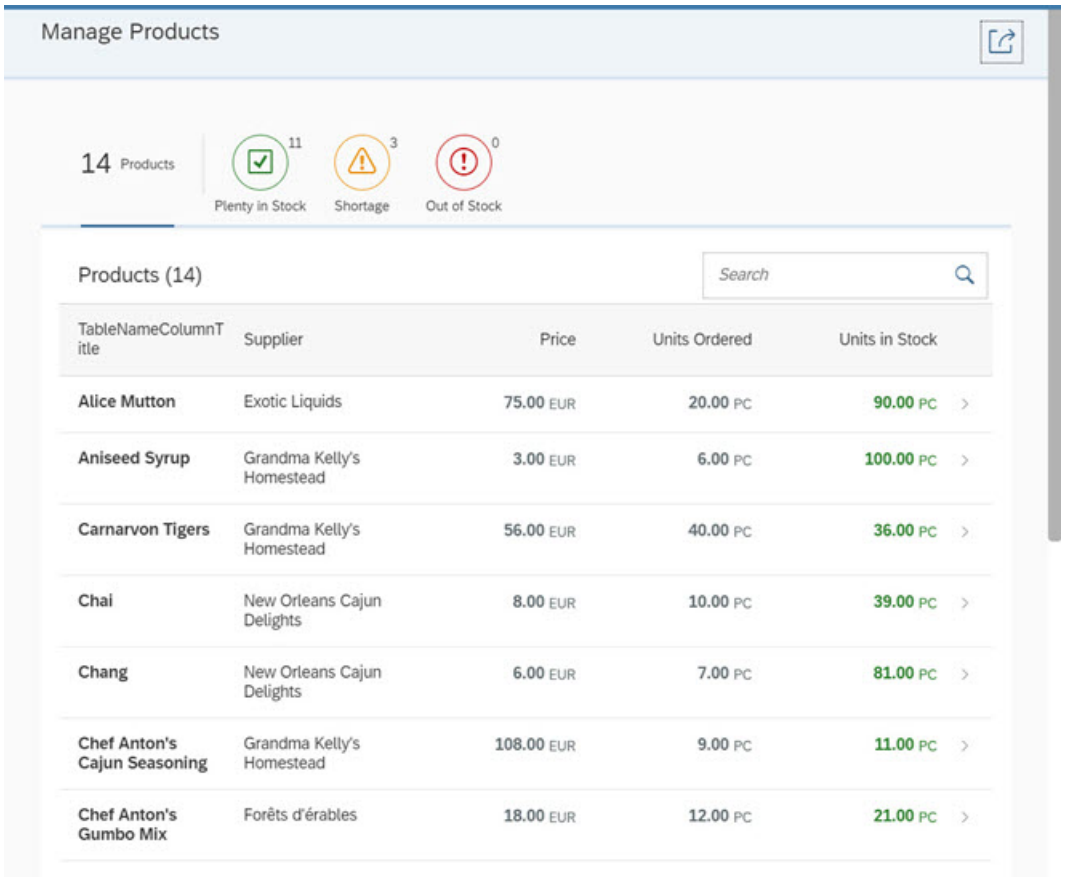

Figure 143: A quick filter allows filtering the product table

Coding

You can view and download all files in the Demo Kit at Worklist App - Step 4.

webapp/view/Worklist.view.xml

```
<mvc:View
    controllerName="myCompany.myApp.controller.Worklist"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:semantic="sap.m.semantic"
    xmlns="sap.m">
    <semantic:FullscreenPage
        id="page"
```

```
        navButtonPress="onNavBack"
        showNavButton="true"
        title="{i18n>worklistViewTitle}">
        <semantic:content>
            <IconTabBar
                id="iconTabBar"
                select=".onQuickFilter"
                expandable="false"
                headerBackgroundDesign="Transparent">
                <items>
                    <IconTabFilter
                        key="all"
                        showAll="true"
                        count="{worklistView>/countAll}"
                        text="{i18n>WorklistFilterProductsAll}"/>
                    <IconTabSeparator/>
                    <IconTabFilter
                        key="inStock"
                        icon="sap-icon://message-success"
                        iconColor="Positive"
                        count="{worklistView>/inStock}"
                        text="{i18n>WorklistFilterInStock}"/>
                    <IconTabFilter
                        key="shortage"
                        icon="sap-icon://message-warning"
                        iconColor="Critical"
                        count="{worklistView>/shortage}"
                        text="{i18n>WorklistFilterShortage}"/>
                    <IconTabFilter
                        key="outOfStock"
                        icon="sap-icon://message-error"
                        iconColor="Negative"
                        count="{worklistView>/outOfStock}"
                        text="{i18n>WorklistFilterOutOfStock}"/>
                </items>
                <content>
                    <Table
...
                    </Table>
                </content>
            </IconTabBar>
        </semantic:content>
        <semantic:sendEmailAction>
            <semantic:SendEmailAction
                id="shareEmail"
                press="onShareEmailPress"/>
        </semantic:sendEmailAction>
    </semantic:FullscreenPage>
</mvc:View>
```

We now update the view and add the new UI for the quick filter to the content aggregation of the `sap.m.SemanticPage` control just before the `table`. It is modeled using a `sap.m.IconTabBar` control and a `sap.m.IconTabFilter` for each of the following filter options:

- *Total Stock*
  This tab will simply show the overall number of products that has been returned by the data service. The `count` property is bound to a local view model and the number will be updated in the controller later in this step. This tab will show a larger number only (optional) and no icon by using the `showAll` property.
- *Out of Stock*
  This tab will show all the products that are out of stock. We choose a matching icon from the icon font and set the icon color to the semantic `Negative` state so that it will appear in red.
- *Shortage*

This tab will show products that have less than 10 pieces remaining with a semantic `Critical` state that will make the icon appear in orange. The count of the number of low stock products will be displayed on the tab and the icon will appear in orange.

- *Plenty in Stock*
  This tab will show products that have more than 10 pieces in stock. The semantic `Positive` state will let the icon appear in green. As usual the UI texts for the tabs are linked to the resource bundle file and will be added later. Do not forget to set the standard CSS class `sapUiNoMarginTop` on the table to remove the spacing between the `IconTabBar` and the `table` and make the UI look nicer.

> **i Note**
>
> Each `IconTabFilter` element has a `key` property that is used to identify the tab that was pressed in the event handler `onQuickFilter` that is registered on the `IconTabBar` control directly. The event handler implementation does the actual filtering on the table and is defined in the controller.

webapp/controller/Worklist.controller.js

```
...
onInit: function() {
    var oViewModel,
        iOriginalBusyDelay,
        oTable = this.byId("table");
    // Put down worklist table's original value for busy indicator delay,
    // so it can be restored later on. Busy handling on the table is
    // taken care of by the table itself.
    iOriginalBusyDelay = oTable.getBusyIndicatorDelay();
    this._oTable = oTable;
    // keeps the search state
    this._oTableSearchState = [];
    // Model used to manipulate control states
    oViewModel = new JSONModel({
        worklistTableTitle:
this.getResourceBundle().getText("worklistTableTitle"),
        shareOnJamTitle: this.getResourceBundle().getText("worklistTitle"),
        shareSendEmailSubject:
this.getResourceBundle().getText("shareSendEmailWorklistSubject"),
        shareSendEmailMessage:
this.getResourceBundle().getText("shareSendEmailWorklistMessage",
[location.href]),
        tableNoDataText: this.getResourceBundle().getText("tableNoDataText"),
        tableBusyDelay: 0,
        inStock: 0,
        shortage: 0,
        outOfStock: 0,
        countAll: 0
    });
    this.setModel(oViewModel, "worklistView");
    // Create an object of filters
    this._mFilters = {
        "inStock": [new Filter("UnitsInStock", "GT", 10)],
        "outOfStock": [new Filter("UnitsInStock", "LE", 0)],
        "shortage": [new Filter("UnitsInStock", "BT", 1, 10)],
        "all": []
    };
    // Make sure, busy indication is showing immediately so there is no
    // break after the busy indication for loading the view's meta data is
    // ended (see promise 'oWhenMetadataIsLoaded' in AppController)
    oTable.attachEventOnce("updateFinished", function() {
        // Restore original busy indicator delay for worklist's table
        oViewModel.setProperty("/tableBusyDelay", iOriginalBusyDelay);
    });
},
```

```
...
```

As a preparation step for the filter tabs we add properties for the counters into the local view model of the worklist controller. We initialize the four values with `0` each. Furthermore, we create an object `_mFilters` that contains a filter for each tab. We will use the filters for filtering the table below the tabs. The properties in `_mFilters` correlate to the keys of the `IconTabFilter` controls we defined above in the `Worklist.view.xml` file. This way we can easily access a filter for a given tab based on the key of the corresponding tab.

Creating a simple filter requires a binding path as first parameter of the filter constructor (e.g. `"UnitsInStock"`), a filter operator (e.g. `"GT"`) as second argument, and a value to compare (e.g. `10`) as the third argument. We create such filters for all three tabs with different filter operators as described in the view part above. Additionally, we create an `all` filter, which is an empty array for clearing the binding again (when the user chooses the *All* tab).

webapp/controller/Worklist.controller.js

```
...
onUpdateFinished: function(oEvent) {
    // update the worklist's object counter after the table update
    var sTitle,
        oTable = oEvent.getSource(),
        oViewModel = this.getModel("worklistView"),
        iTotalItems = oEvent.getParameter("total");
    // only update the counter if the length is final and
    // the table is not empty
    if (iTotalItems && oTable.getBinding("items").isLengthFinal()) {
        sTitle = this.getResourceBundle().getText("worklistTableTitleCount",
[iTotalItems]);
        // Get the count for all the products and set the value to 'countAll'
property
        this.getModel().read("/Products/$count", {
            success: function (oData) {
                oViewModel.setProperty("/countAll", oData);
            }
        });
        // read the count for the unitsInStock filter
        this.getModel().read("/Products/$count", {
            success: function (oData) {
                oViewModel.setProperty("/inStock", oData);
            },
            filters: this._mFilters.inStock
        });
        // read the count for the outOfStock filter
        this.getModel().read("/Products/$count", {
            success: function(oData){
                oViewModel.setProperty("/outOfStock", oData);
            },
            filters: this._mFilters.outOfStock
        });
        // read the count for the shortage filter
        this.getModel().read("/Products/$count", {
            success: function(oData){
                oViewModel.setProperty("/shortage", oData);
            },
            filters: this._mFilters.shortage
        });
    } else {
        sTitle = this.getResourceBundle().getText("worklistTableTitle");
    }
    this.getModel("worklistView").setProperty("/worklistTableTitle", sTitle);
},
...
```

In the `onUpdateFinished` function, we get the count of all products by triggering a read operation on the model with the appropriate filter. The filter is a helper object of SAPUI5 that defines the condition for each tab on the data binding level. We already created the filters in the `onInit` function.

> **i** Note
>
> The `v2.ODataModel` will automatically bundle these `read` requests to one batch request to the server (if batch mode is enabled).

In the `success` handler of each `read` operation we update the corresponding property in the view model with the real count of the matching items that were returned by the service.

webapp/controller/Worklist.controller.js

```
...
_applySearch: function(oTableSearchState) {
    ...
},
/**
 * Event handler when a filter tab gets pressed
 * @param {sap.ui.base.Event} oEvent the filter tab event
 * @public
 */
onQuickFilter: function(oEvent) {
    var oBinding = this._oTable.getBinding("items"),
        sKey = oEvent.getParameter("selectedKey");
    oBinding.filter(this._mFilters[sKey]);
}
...
```

Next, we implement the handler for the `select` event of the `IconTabBar`. In this event handler we get a reference to the binding for the `items` aggregation of our `table` and store it in the variable `oBinding`. Then we read the parameter `selectedKey` from the `event` object to find out which tab has been selected. This `selectedKey` is used to get the correct filter for the selected tab. Next, we simply call the filter method on `oBinding` and pass the correct filter of the selected tab.

The filters are always applied as an array on the binding level, so you don't need to take care of managing the data, the data binding features of SAPUI5 will automatically take care.

webapp/i18n/i18n.properties

```
...

#XTIT: The title of the products quick filter
WorklistFilterProductsAll=Products

#XTIT: The title of the out of stock products filter
WorklistFilterOutOfStock=Out of Stock

#XTIT: The title of the low stock products filter
WorklistFilterShortage=Shortage

#XTIT: The title of the products in stock filter
WorklistFilterInStock=Plenty in Stock
#~~~ Object View ~~~~~~~~~~~~~~~~~~~~~~~~~~
...
```

We finally add the texts for the tab filters to the resource bundle. Copy the text definitions from the code section above to the end of the `Worklistn View` section in the i18n file.

Now run the app again and click the filter icons on top of the table. The products should be filtered according to the selection in the filter bar and the count should match the number of items displayed.

Related Information

API Reference: `sap.ui.model.ListBinding.filter`

Step 5: Adding Actions to the Worklist

Now we can easily spot shortages on our stock, but we would also like to take action and resolve it. Either we can decide to remove the product until the shortage is resolved or order new items of the product. In this step, we will add these actions to the footer of the worklist table.

Preview

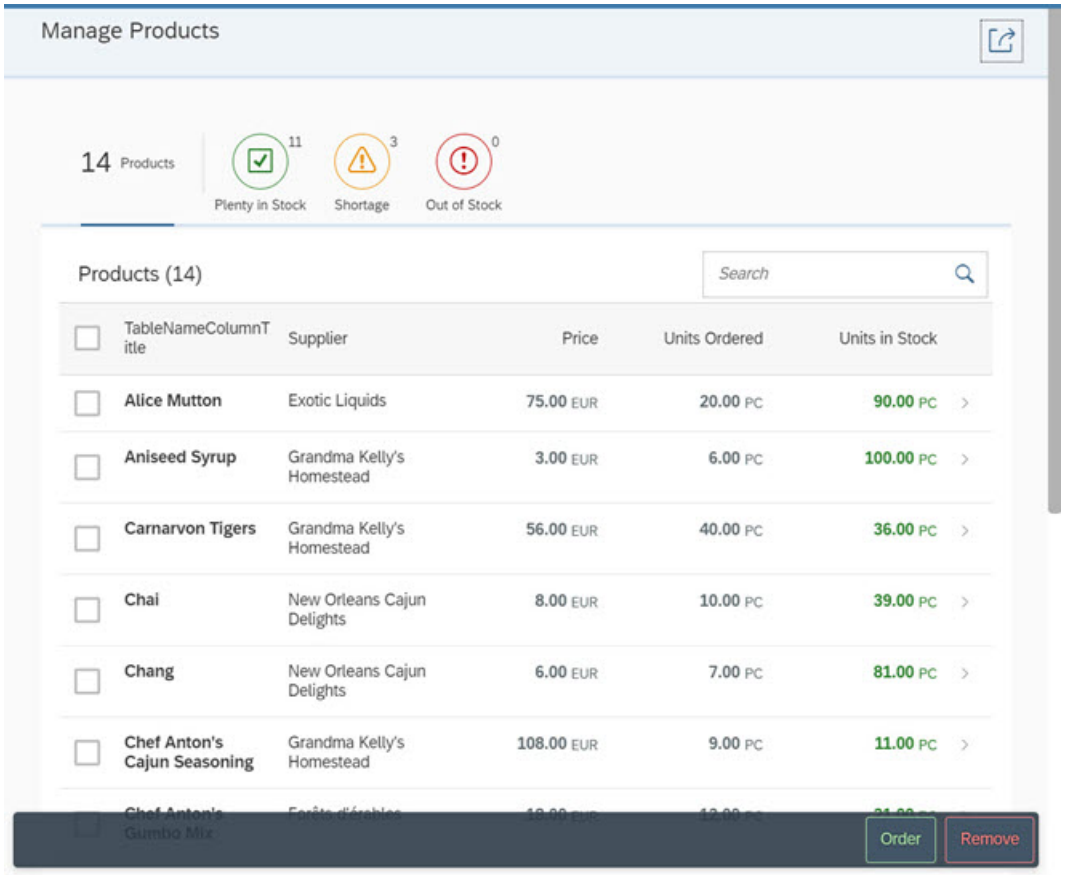

Figure 144: Actions are now available in the footer bar

Coding

You can view and download all files in the *Samples* in the Demo Kit at Worklist App - Step 5.

webapp/view/Worklist.view.xml

```
...
<Table
    id="table"
    busyIndicatorDelay="{worklistView>/tableBusyDelay}"
    growing="true"
    growingScrollToLoad="true"
    noDataText="{worklistView>/tableNoDataText}"
    updateFinished=".onUpdateFinished"
    width="auto"
    mode="MultiSelect"
    items="{
        path: '/Products',
        sorter: {
            path: 'ProductName',
            descending: false
        },
        parameters: {
            'expand': 'Supplier'
        }
    }">
...
```

We change the table `mode` to `MultiSelect`. This allows you to select multiple items in the table. Below, we will add two buttons to the footer bar of the screen. The first button will add to the `UnitsInStock` property, and the second will remove the selected products.

webapp/view/Worklist.view.xml

```
<mvc:View
     controllerName="mycompany.myapp.MyWorklistApp.controller.Worklist"
     xmlns="sap.m"
     xmlns:mvc="sap.ui.core.mvc"
     xmlns:semantic="sap.f.semantic">
     <semantic:SemanticPage
          id="page"
          headerPinnable="false"
          toggleHeaderOnTitleClick="false"
          showFooter="true">
          <semantic:titleHeading>
                <Title text="{i18n>worklistTitle}"/>
          </semantic:titleHeading>
          ...
     </semantic:content>
     <semantic:sendEmailAction>
          <semantic:SendEmailAction id="shareEmail" press=".onShareEmailPress"/>
     </semantic:sendEmailAction>
     <semantic:positiveAction>
          <semantic:PositiveAction text="{i18n>TableProductsReorder}"
press=".onUpdateStockObjects"/>
     </semantic:positiveAction>
     <semantic:negativeAction>
          <semantic:NegativeAction text="{i18n>TablePorductsUnlist}"
press=".onUnlistObjects"/>
     </semantic:negativeAction>
</semantic:SemanticPage>
...
```

Now we add the buttons to the footer bar of the page. The two semantic actions `Negative` and `Positive` will automatically be positioned in the footer bar. The first button will order new items of the selected products and the second one will remove them. The corresponding event handlers will be implemented in the controller.

webapp/controller/Worklist.controller.js

```
sap.ui.define([
    "./BaseController",

            // we could create a counter for successful and one for failed
requests
            // however, we just assume that every single request was successful
and display a success message once
            if (iRequestNumber === iTotalRequests) {

MessageToast.show(this.getModel("i18n").getResourceBundle().getText("StockUpdated
SuccessMsg", [iTotalRequests]));
            }
        },

        /**
         * Event handler for the unlist button. Will delete the
         * product from the (local) model.
         * @public
         */
        onUnlistObjects: function() {
            var aSelectedProducts, i, sPath, oProduct, oProductId;

            aSelectedProducts = this.byId("table").getSelectedItems();
            if (aSelectedProducts.length) {
                for (i = 0; i < aSelectedProducts.length; i++) {
                    oProduct = aSelectedProducts[i];
                    oProductId =
oProduct.getBindingContext().getProperty("ProductID");
                    sPath = oProduct.getBindingContext().getPath();
                    this.getModel().remove(sPath, {
                        success : this._handleUnlistActionResult.bind(this,
oProductId, true, i+1, aSelectedProducts.length),
                        error : this._handleUnlistActionResult.bind(this,
oProductId, false, i+1, aSelectedProducts.length)
                    });
                }
            } else {

this._showErrorMessage(this.getModel("i18n").getResourceBundle().getText("TableSe
lectProduct"));
            }
        },

        /**
         * Event handler for the reorder button. Will reorder the
         * product by updating the (local) model
         * @public
         */
        onUpdateStockObjects: function() {
            var aSelectedProducts, i, sPath, oProductObject;

            aSelectedProducts = this.byId("table").getSelectedItems();
            if (aSelectedProducts.length) {
                for (i = 0; i < aSelectedProducts.length; i++) {
                    sPath = aSelectedProducts[i].getBindingContext().getPath();
                    oProductObject =
aSelectedProducts[i].getBindingContext().getObject();
                    oProductObject.UnitsInStock += 10;
                    this.getModel().update(sPath, oProductObject, {
```

```
                        success : this._handleReorderActionResult.bind(this,
oProductObject.ProductID, true, i+1, aSelectedProducts.length),
                        error : this._handleReorderActionResult.bind(this,
oProductObject.ProductID, false, i+1, aSelectedProducts.length)
                    });
                }
            } else {

this._showErrorMessage(this.getModel("i18n").getResourceBundle().getText("TableSe
lectProduct"));
            }
        }
    });
});
```

Let's have a look at the implementation of the event handlers for the new actions. We first load the `sap.m.MessageToast` control as a new dependency to display a success message for the `unlist` and `reorder` actions.

Both actions are similar from an implementation perspective and the details are described below. They both loop over the selected items in the table and trigger a model update or deletion on the selected path. After that, a success message with the number of products processed is displayed. The table is updated automatically by the model change.

- *Order*
  For each of the selected items the binding path in the model is retrieved by calling the helper method `getBindingContextPath` on the selected item. Additionally, the data object from the model is fetched by calling `getBindingContext().getObject()` on the item. We update the data object and simply add `10` items to the stock to keep things simple in this example. Then we call the update function on the model with the product path and the new object. This will trigger an OData update request to the back end and a refresh of the model afterwards (multiple requests are handled together in batch mode). When the model refreshes, the table will be updated as well because of its binding.
- *Remove*
  For each of the selected items the binding path in the model is retrieved by calling the helper method `getBindingContextPath` on the selected item. Then, we call the `remove` function on the model with the product path. This triggers an OData `delete` request to the back end and a refresh of the OData model afterwards. Again, when the model is refreshed, the table will be updated as well because of its binding. The ODataModel v2 collects all these requests and only sends one batch request (this default behavior can be changed).

For each action we register both a `success` handler and an `error` handler. The `success` handler and `error` handler for each action is the same, but the function is called with different parameters. This allows us to use the same handler function for both the error and success case. Inside the corresponding handlers we simply display a success message once by comparing the current request number with the total number of requests. Furthermore, we assume that all of our requests always succeed.

In a real scenario, you could have a counter for error responses, and one for success responses. Finally, you could implement you own business logic for error and success cases, like displaying the number of failed and succeeded requests together with the corresponding product identified by the product ID parameter of the handlers. We don't do this to keep things simple.

> **i Note**
>
> In our example, the remove or order actions are only applied to items that are visible in the table, even if the *Select All* checkbox of the table is selected. Keep in mind that there may be more data on the back end that is currently not loaded, and therefore it is neither displayed and nor can it be selected by the user.

If you want to change this behavior, you might need to change both back-end and front-end code.

webapp/i18n/i18n.properties

```
...
#text of the button for Products reordering
TableProductsReorder=Order

#text for the button for Products unlisting
TablePorductsUnlist=Remove

#Text for no product selected
TableNoProductsSelected=No product selected

#Product successfully deleted
StockRemovedSuccessMsg=Product removed

#Product successfully updated
StockUpdatedSuccessMsg=Product stock level updated
#~~~ Object View ~~~~~~~~~~~~~~~~~~~~~~~~~~
...
```

Add the missing texts for the buttons and the message toast.

Save the changes and run the application again. Try the *Order* and *Remove* buttons with one or more products selected. The stock value will be increased or the product will be (temporarily) removed from the worklist table. Since all of our changes happen on a local mock server, we can simply reload the app to reset the data again.

Step 6: Extending the Detail Page

In this step, we will extend the detail page of our app to show more information of a given product with various UI controls. We will enrich the header area and display further attributes in an info panel for information about the supplier.

{i18n>ObjectSupplierCity}"/>
                        <Text text="{Supplier/PostalCode} / {Supplier/City}"/>
                        <Label text="{i18n>ObjectSupplierCountry}"/>
                        <Text text="{Supplier/Country}"/>
                    </form:content>
                </form:SimpleForm>
            </content>
        </Panel>
    </semantic:content>
```

```
    <semantic:sendEmailAction>
        <semantic:SendEmailAction id="shareEmail" press="onShareEmailPress"/>
    </semantic:sendEmailAction>
</semantic:SemanticPage>
</mvc:View>
```

We define a new `headerContent` section as well as some additional attributes for the product with two `sap.m.ObjectAttribute` controls, one for the `Price` and one for the `ProductID`. These are important product attributes for us, so we want to include them in our header area.

To get a better visual representation of the current stock of the shown product, we use the `ObjectStatus` and `ProgressIndicator` control statuses. If our product will not be produced anymore, the `ObjectStatus` shows up as *Discontinued*. The `ProgressIndicator` uses the same formatter function as our `UnitsInStock` (in the `state` of the `ObjectNumber`).

Below the object header we can use `sap.m.Panel` to display some additional information in a nice layout on the page. Inside the panel we use `sap.ui.layout.form.SimpleForm` to align the labels and texts we want to display.

webapp/i18n/i18n.properties

```
...
#Price per unit text
ObjectPriceTitle=Price

#Discontinued text
ObjectDiscontinuedStatusText=Discontinued

#Supplier tab title
ObjectSupplierTabTitle=Supplier Info

#Supplier company name
ObjectSupplierName=Name

#Supplier contact person name
ObjectSupplierContact=Contact

#Supplier contact address
ObjectSupplierAddress=Address

#Supplier zip code
ObjectSupplierZipcode=ZIP Code

#Supplier city name
ObjectSupplierCity=City

#Supplier country
ObjectSupplierCountry=Country

#Object Product ID text
ObjectProductIdText=Product ID
#~~~ Footer Options ~~~~~~~~~~~~~~~~~~~~~~
...
```

As before, we add new i18n texts to the resource bundle.

Save all the changes and run the application. Click on any product and see the product details displayed on the detail page.

Step 7: Adding a Comments Section

In this step, we extend the product detail view by adding a feature allowing to add comments to the product.

Preview

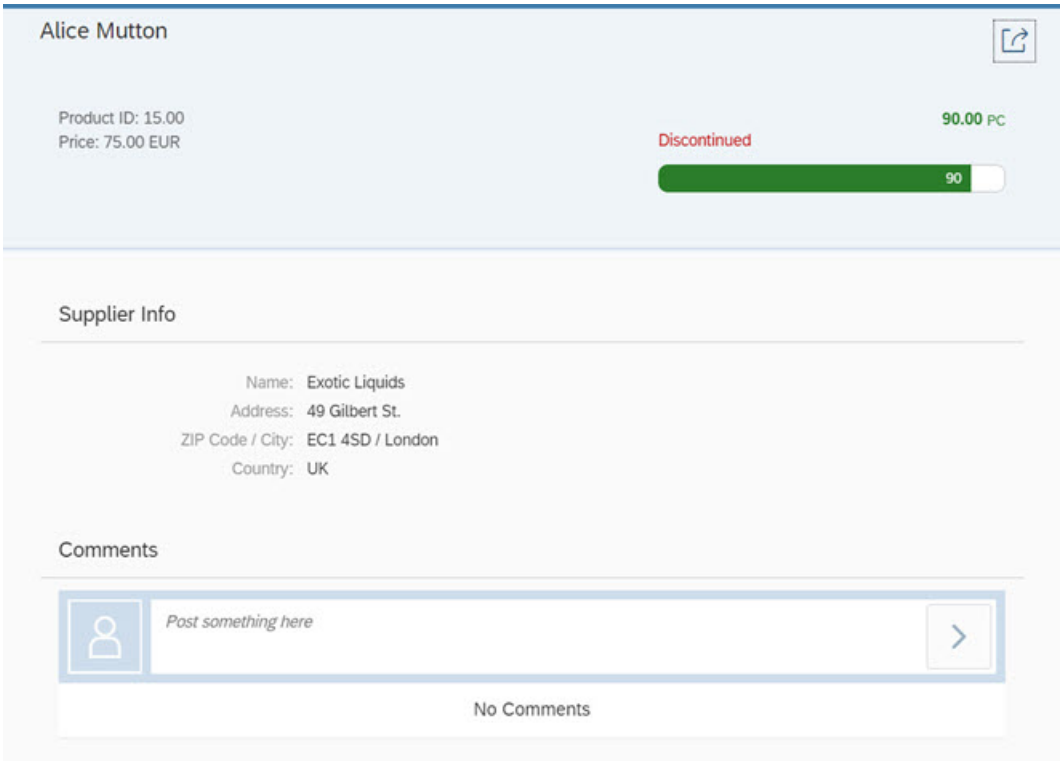

Figure 146: Comments section added to the detail page

Coding

You can view and download all files in the *Samples* in the Demo Kit at Worklist App - Step 7 .

webapp/view/Object.view.xml

```
<mvc:View
    controllerName="mycompany.myapp.MyWorklistApp.controller.Object"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:semantic="sap.f.semantic"
    xmlns:form="sap.ui.layout.form"
    xmlns:l="sap.ui.layout">
...
        <semantic:content>
            <l:VerticalLayout width="100%">
            <Panel
                backgroundDesign="Transparent"
                headerText="{i18n>ObjectSupplierTabTitle}">
...
```

```
            </Panel>
                <Panel
                    backgroundDesign="Transparent"
                    headerText="{i18n>ObjectCommentsTabTitle}">
                    <content>
                        <FeedInput post=".onPost"/>
                        <List
                            id="idCommentsList"
                            noDataText="{i18n>ObjectCommentNoData}"
                            showSeparators="Inner"
                            items="{
                                path: 'productFeedback>/productComments',
                                sorter: {
                                    path: 'date',
                                    descending: true
                                }
                            }">
                            <FeedListItem
                                info="{productFeedback>type}"
                                text="{productFeedback>comment}"
                                timestamp="{productFeedback>date}"/>
                        </List>
                    </content>
                </Panel>
            </l:VerticalLayout>
        </semantic:content>
```

Below the already existing panel, we add another panel that will serve as a container for our comments section. We put both panels inside a vertical layout, because `sap.f.semanticPage` allows only one control for content aggregation. Within the new panel, we add a `sap.m.FeedInput` control and attach an event handler `onPost` for the `post` event. This control will render an input field and a button, which allow users to post comments. The event handler we registered will be implemented below.

Below the `FeedInput` control, we add a list with all existing comments. The `items` aggregation of the list is bound to the `/productComments` property of the named model `productFeedback` that we will create below. All comments shall be displayed in descending order based on their publishing date. Therefore, we also configure a sorter for our items in the list.

The template for each row is a `FeedListItem` control. We configure the `FeedListItem` to simply display the date of the post, the text of the post itself, and the type of the post.

webapp/controller/Object.controller.js

```
...
/*global location*/
sap.ui.define([
   "myCompany/myApp/controller/BaseController",
   "sap/ui/model/json/JSONModel",
   "sap/ui/core/routing/History",
   "myCompany/myApp/model/formatter",
   "sap/ui/core/format/DateFormat",
   "sap/ui/model/Filter",
   "sap/ui/model/FilterOperator"
], function(BaseController, JSONModel, History, formatter, DateFormat, Filter,
FilterOperator) {
   "use strict";
   return BaseController.extend("myCompany.myApp.controller.Object", {
      formatter: formatter,
      ...
      _onBindingChange: function(oEvent) {
         ...
         // Update the comments in the list
         var oList = this.byId("idCommentsList");
         var oBinding = oList.getBinding("items");
```

```
            oBinding.filter(new Filter("productID", FilterOperator.EQ, sObjectId));
        },
        /**
        * Updates the model with the user comments on Products.
        * @function
        * @param {sap.ui.base.Event} oEvent object of the user input
        */
        onPost: function (oEvent) {
            var oFormat = DateFormat.getDateTimeInstance({style: "medium"});
            var sDate = oFormat.format(new Date());
            var oObject = this.getView().getBindingContext().getObject();
            var sValue = oEvent.getParameter("value");
            var oEntry = {
                productID: oObject.ProductID,
                type: "Comment",
                date: sDate,
                comment: sValue
            };
            // update model
            var oFeedbackModel = this.getModel("productFeedback");
            var aEntries = oFeedbackModel.getData().productComments;
            aEntries.push(oEntry);
            oFeedbackModel.setData({
               productComments : aEntries
            });
        }
    });
});
```

First, we add three new dependencies to the controller. We need these dependencies because we want to create a filter for the list and because we format the date and time of each post.

Whenever the binding of the detail view changes, we want to make sure that the comments for the current product are displayed. Therefore, we change the private function `_onBindingChange` and update the filter of the list that displays the comments by getting a reference to the binding of the `items` aggregation of our list and calling the `filter()` API afterwards. The filter is passed on to the `filter()` API. We use the `productID` as filter criterion, because we only want comments for a specific product.

Next, the event handler for the `post` event of the `FeedInput` is implemented. In the `onPost` handler, we create a new `entry` object that contains all data we want to store in our model. This data is the `productId`, the `type` of the post (hard-coded in our example), the current `date` in a medium date format, and the `comment` itself. The comment is retrieved from the event object. The `productId` is determined by calling `getObject()` on the view's binding context.

Finally, the new entry is added to the named model called `productFeedback`. This model does not exist yet, so let's create it next.

webapp/model/models.js

```
sap.ui.define([
    "sap/ui/model/json/JSONModel",
    "sap/ui/Device"
], function(JSONModel, Device) {
    "use strict";
    return {
        createDeviceModel: function() {
            var oModel = new JSONModel(Device);
            oModel.setDefaultBindingMode("OneWay");
            return oModel;
        },
        createCommentsModel: function() {
            return new JSONModel({ productComments : [] });
        }
```

```
    };
});
```

In both the object view (detail page) as well as in the corresponding controller we used a named model called `productFeedback`. In our example this model is a simple `JSONModel`. It is created in the function `createCommentsModel()` in the `model.js` file. As you can see above, the function simply returns a new instance of a `JSONModel` with a simple data object. The property `productComments` is an empty array and it will be updated every time someone posts a new comment.

However, this model is not yet accessible throughout our app. Let's fix this next.

webapp/Component.js

```
sap.ui.define([
   "sap/ui/core/UIComponent",
   "sap/ui/Device",
   "./model/models",
   "./controller/ErrorHandler"
], function(UIComponent, Device, models, ErrorHandler) {
   "use strict";
   return UIComponent.extend("myCompany.myApp.Component", {
      ...
      init: function() {
         // call the base component's init function
         UIComponent.prototype.init.apply(this, arguments);
         // initialize the error handler with the component
         this._oErrorHandler = new ErrorHandler(this);
         // set the device model
         this.setModel(models.createDeviceModel(), "device");

         // set the product feedback model
         this.setModel(models.createCommentsModel(), "productFeedback");
         // create the views based on the url/hash
         this.getRouter().initialize();
      },
      ...
   });
});
```

Now it's time to make the named model `productFeedback` available to our app. Therefore, just change the `init` function of our `Component.js` file by calling our `createCommentsModel()` method and setting the returned model on the component. After this, our model is accessible in our app.

webapp/i18n/i18n.properties

```
...
#Comments tab title
ObjectCommentsTabTitle=Comments

#No comments text
ObjectCommentNoData=No Comments
#~~~ Footer Options ~~~~~~~~~~~~~~~~~~~~~
...
```

Now add the new texts to our `i18n.properties` file and you're done.

You can test the new features by navigating to the details page of any given product. After that, just create a new comment for that product and post it.

Summary

You have learned how to use SAP Web IDE to create a simple worklist app from a template and you know where to find the code in the *Samples*. Based on the initial app you have seen how easy it can be to generate or download initial code and to extend it according to your own requirements. This tutorial also illustrated how to communicate easily with an OData back end using the OData V2 model. Furthermore, it illustrated how to use the mock server with both generated mock data and more realistic data.

SAP Fiori 2.0 App

In this tutorial, we showcase how to structure your SAPUI5 app using the layout patterns that comply with the latest SAP Fiori design guidelines.

The app provides the following features:

- An up-to-three-column layout based on the `sap.f.FlexibleColumnLayout` control. This layout has predefined layout types and defined routing between them that enables smooth navigation between the master-detail and master-detail-detail patterns of the app.
- A master page based on the `sap.f.DynamicPage` control that lists the available products and has filtering and sorting options.
- A detail page based on the `sap.uxap.ObjectPageLayout` control containing detailed information about the selected object from the master page:
  - It implements the dynamic header of the `ObjectPageLayout` control.
  - The `sap.f.Avatar` control is used in the title area to display an image of the selected product.
  - The header title area can be collapsed (snapped to the title) by scrolling down the content of the page or by clicking/tapping the title area. The header area can also be pinned so that it remains visible when the user scrolls down the content of the page.
  - The title area has a set of actions on the right. The title area can display specific content when the header is snapped.
  - The floating footer is positioned at the bottom of the page, on top of the page content. It holds finalizing actions on the right.
- A detail-detail page based on `sap.f.DynamicPage` to display further details of the selected object from the detail page.
- A simple about page based on `sap.f.DynamicPage` to display further details of the selected object from the detail-detail page.

Preview

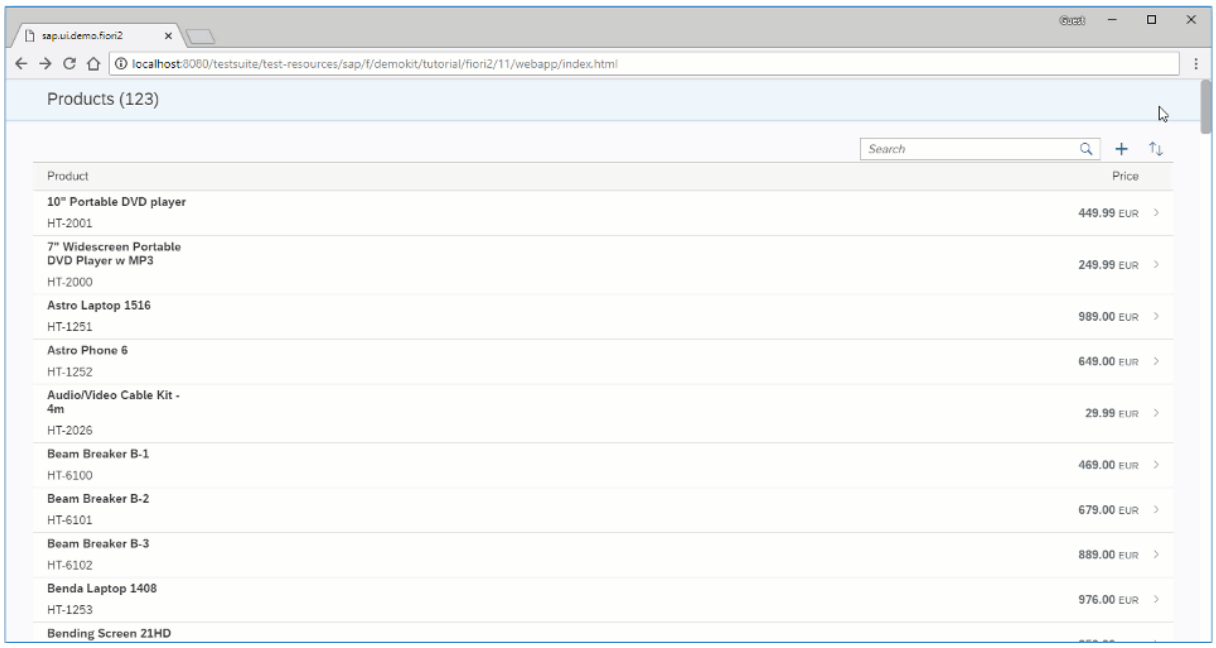

Figure 147: Master-detail-detail pattern with `sap.f.FlexibleColumnLayout`, `sap.f.DynamicPage` and `sap.uxap.ObjectPageLayout`

Choose your development environment

You can do this tutorial either with SAP Web IDE or choose your own development environment:

- If you use SAP Web IDE, you don't need to set up a development environment, a server and so on. All you need is a browser and an account for the SAP Cloud Platform. If you don't have an account yet, you can easily get a trial account. We recommend to continue with the SAP Web IDE as it has out-of-the-box support for SAPUI5 and because there is no setup overhead at all.
  In this case, you start with the template that is available in SAP Web IDE as described in step 1 of this tutorial.
- If you want to use your local development environment and deploy to any Web server of your choice, you can download the code for step 1 from the *Samples* in the Demo Kit at SAP Fiori 2.0 App - Step 1.

> → Tip
>
> You don't have to do all tutorial steps sequentially, you can also jump directly to any step you want. Just download the code from the previous step, copy it to your workspace and make sure that the app runs by calling the `webapp/index.html` file.
>
> For more information check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):
>
> - Downloading Code for a Tutorial Step [page 40]
> - Adapting Code to Your Development Environment [page 40]

Step 1: Setting Up the Initial App

We start by setting up a basic SAPUI5 app for this tutorial.

The structure in this step will be used throughout the rest of this tutorial. The basic SAPUI5 app created in this step will be extended in the subsequent steps to illustrate the main features of an SAP Fiori 2.0 app.

Prerequisites

You have set up your SAP Web IDE as described under App Development Using SAP Web IDE [page 44].

> **i Note**
>
> If your preferred development environment is not SAP Web IDE, you can skip the instructions below and set up your project for this tutorial by directly downloading the files for the initial app from the *Samples* in the Demo Kit at SAP Fiori 2.0 App - Step 1. Copy the code to your workspace and make sure that the app runs by calling the `webapp/index.html` file.

Preview

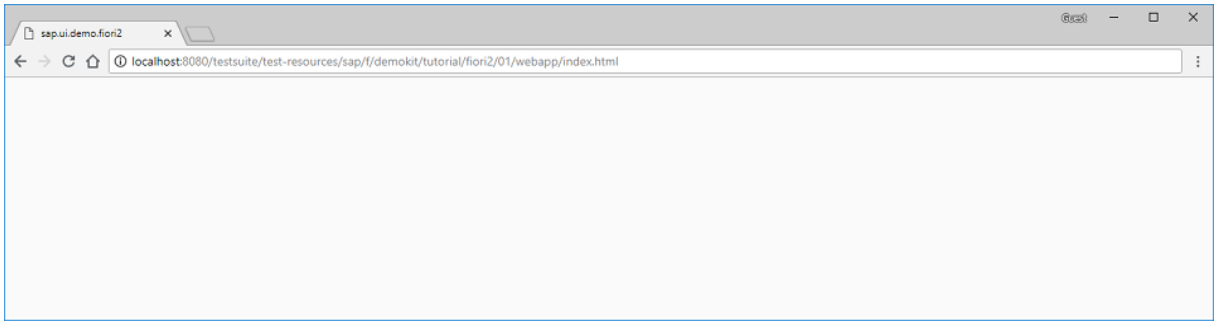

Figure 148: The basic SAPUI5 app

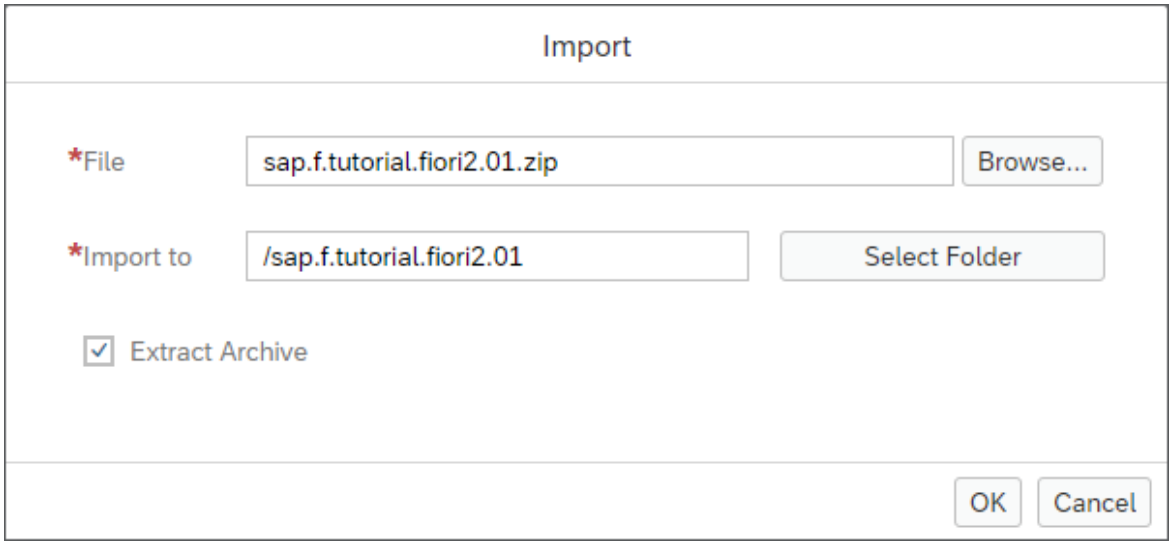
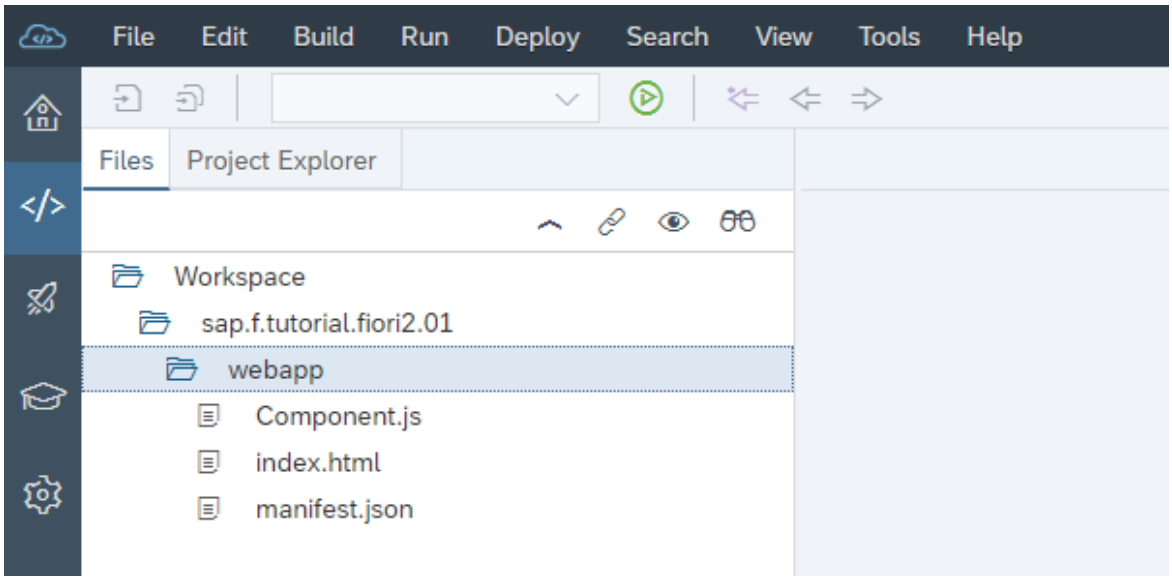
Create the Initial App Using the SAP Web IDE Import Functionality

1. Download the code for the initial app from the *Samples* in the Demo Kit at SAP Fiori 2.0 App - Step 1.
2. Launch SAP Web IDE.
3. Choose *File* > *Import* > *File or Project*
4. Choose *Browse* and select the downloaded `sap.f.tutorial.fiori2.01.zip` file, then choose *Open*.



5. Make sure *Extract Archive* is checked and choose *OK*.
   A new folder `sap.ui.demo.fiori2.01` is now available in your local workspace. It contains the following files and folders of the initial app:



6. Run the app by selecting the *webapp* folder and then *Run* > *Run as* > *Web Application*. Keep in mind that there is no content yet and the app appears as an empty page.

From now on, you can quickly run the app by selecting the root folder `sap.ui.demo.fiori2` of your project in SAP Web IDE and pressing the *Run* button. The system will automatically use the option from the *Run* menu that you chose last (in this case, the *Run index.html* option).

Step 2: Creating an Empty Flexible Column Layout

In this step, we add an instance of the `sap.f.FlexibleColumnLayout` in the main view of the app.

Preview

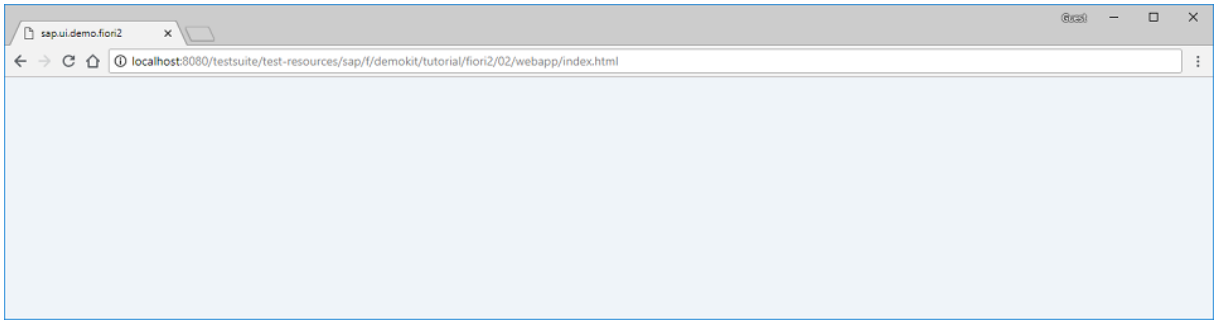


Figure 149: An empty instance of the **`sap.f.FlexibleColumnLayout`** control

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 2.

webapp/manifest.json [MODIFY]

```
{
    "_version": "1.12.0",
    "sap.app": {
        "id": "sap.ui.demo.fiori2",
        "type": "application",
        "applicationVersion": {
            "version": "1.0.0"
        }
    },
    "sap.ui5": {
        "rootView": {
            "viewName": "sap.ui.demo.fiori2.view.App",
            "type": "XML",
            "async": true,
            "id": "fcl"
        },
        "dependencies": {
            "minUI5Version": "1.60.0",
            "libs": {
                "sap.ui.core": {},
                "sap.f": {}
            }
        },
        "config": {
            "fullWidth": true
        }
    }
```

```
}
```

First, we add the `sap.f` library as a dependency in the `manifest.json` file as most of the SAP Fiori 2.0 controls are in this library.

webapp/view/App.view.xml [NEW]

```
<mvc:View
    displayBlock="true"
    height="100%"
    xmlns="sap.f"
    xmlns:mvc="sap.ui.core.mvc">
        <FlexibleColumnLayout id="flexibleColumnLayout"
backgroundDesign="Solid"></FlexibleColumnLayout>
</mvc:View>
```

We create a new `App.view.xml` that contains an instance of the `sap.f.FlexibleColumnLayout` control. Keep in mind that there is no content yet and the app appears as an empty page.

webapp/manifest.json [MODIFY]

```
{
    "_version": "1.12.0",
    "sap.app": {
        "id": "sap.ui.demo.fiori2",
        "type": "application",
        "applicationVersion": {
            "version": "1.0.0"
        }
    },
    "sap.ui5": {
        "rootView": {
            "viewName": "sap.ui.demo.fiori2.view.App",
            "type": "XML",
            "async": false,
            "id": "fcl"
        },
        "dependencies": {
            "minUI5Version": "1.60.0",
            "libs": {
                "sap.ui.core": {},
                "sap.f": {}
            }
        },
        "config": {
            "fullWidth": true
        }
    }
}
```

We set the `rootView` to point to the created `App.view.xml`.

Step 3: Using Dynamic Page for the Master View

In this step, we create the master view of the app using `sap.f.DynamicPage` control.

Preview

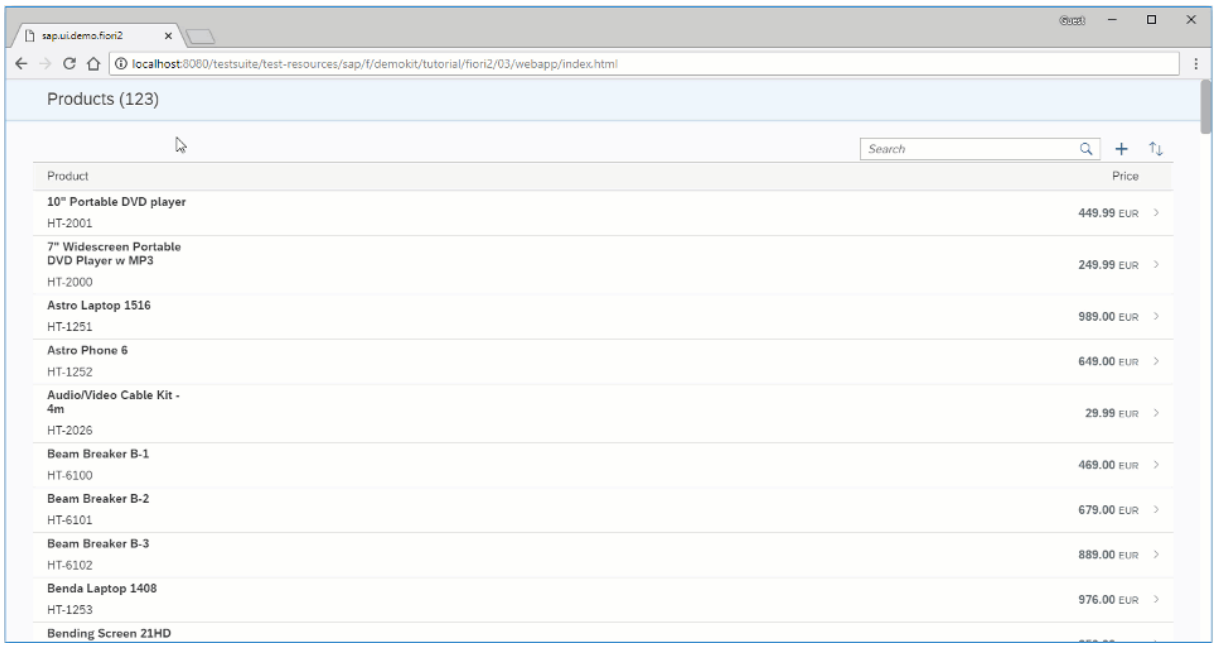

Figure 150: Master page with `sap.f.DynamicPage`

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 3.

webapp/manifest.json [MODIFY]

```
{
    "_version": "1.12.0",
    "sap.app": {
        "id": "sap.ui.demo.fiori2",
        "type": "application",
        "applicationVersion": {
            "version": "1.0.0"
        }
    },
    "sap.ui5": {
        "rootView": {
            "viewName": "sap.ui.demo.fiori2.view.App",
            "type": "XML",
            "async": true,
```

```
            "id": "fcl"
        },
        "dependencies": {
            "minUI5Version": "1.60.0",
            "libs": {
                "sap.ui.core": {},
                "sap.m": {},
                "sap.f": {}
            }
        },
        "config": {
            "fullWidth": true
        }
    }
}
```

First, we add the `sap.m` library as a dependency in the `manifest.json`.

webapp/index.html [MODIFY]

```
    ...
    <script id="sap-ui-bootstrap"
        src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-resourceroots='{
            "sap.ui.demo.fiori2": "./",
            "sap.ui.demo.mock": "https://openui5.hana.ondemand.com/test-
resources/sap/ui/documentation/sdk/"
        }'
        data-sap-ui-oninit="module:sap/ui/core/ComponentSupport"
        data-sap-ui-compatVersion="edge"
        data-sap-ui-async="true"
        data-sap-ui-frameOptions="trusted">
    </script>
    ...
```

We add the link to the mock data that is used in the app.

webapp/Component.js [MODIFY]

```
sap.ui.define([
    'sap/ui/core/UIComponent',
    'sap/ui/model/json/JSONModel'
], function(UIComponent, JSONModel) {
    'use strict';
    return UIComponent.extend('sap.ui.demo.fiori2.Component', {
        metadata: {
            manifest: 'json'
        },

        init: function () {
            var oProductsModel;

            UIComponent.prototype.init.apply(this, arguments);

            // set products demo model on this sample
            oProductsModel = new JSONModel(sap.ui.require.toUrl('sap/ui/demo/
```

```
mock') + '/products.json');
            oProductsModel.setSizeLimit(1000);
            this.setModel(oProductsModel, 'products');
        }
    });
});
```

We create the `init` method in the `Component.js` to set the model.

webapp/view/Master.view.xml [NEW]

```
<mvc:View
    controllerName="sap.ui.demo.fiori2.controller.Master"
    xmlns="sap.m"
    xmlns:f="sap.f"
    xmlns:mvc="sap.ui.core.mvc">
    <f:DynamicPage id="dynamicPageId" toggleHeaderOnTitleClick="false">
        <!-- DynamicPage Title -->
        <f:title>
            <f:DynamicPageTitle>
                <f:heading>
                    <Title text="Products ({products>/ProductCollectionStats/
Counts/Total})"/>
                </f:heading>
            </f:DynamicPageTitle>
        </f:title>

        <!-- DynamicPage Content -->
        <f:content>
            <VBox fitContainer="true">
                <OverflowToolbar class="sapFDynamicPageAlignContent">
                    <ToolbarSpacer/>
                    <SearchField search=".onSearch" width="17.5rem"/>
                    <OverflowToolbarButton icon="sap-icon://add" text="Add"
type="Transparent" press=".onAdd"/>
                    <OverflowToolbarButton icon="sap-icon://sort" text="Sort"
type="Transparent" press=".onSort"/>
                </OverflowToolbar>
                <Table
                    id="productsTable"
                    inset="false"
                    items="{
                        path: 'products>/ProductCollection',
                        sorter: {
                            path: 'Name'
                        }
                    }"
                    class="sapFDynamicPageAlignContent"
                    width="auto">
                    <columns>
                        <Column width="12em">
                            <Text text="Product"/>
                        </Column>
                        <Column    hAlign="End">
                            <Text text="Price"/>
                        </Column>
                    </columns>
                    <items>
                        <ColumnListItem type="Navigation">
                            <cells>
                                <ObjectIdentifier title="{products>Name}"
text="{products>ProductId}"/>
                                <ObjectNumber
```

```
                                    number="{
                                        parts:[
                                            {path:'products>Price'},
                                            {path:'products>CurrencyCode'}
                                        ],
                                        type: 'sap.ui.model.type.Currency',
                                        formatOptions: {showMeasure: false}
                                    }"
                                    unit="{products>CurrencyCode}"/>
                            </cells>
                        </ColumnListItem>
                    </items>
                </Table>
            </VBox>
        </f:content>

        <!-- DynamicPage Footer -->
        <f:footer>
            <OverflowToolbar>
                <ToolbarSpacer/>
                <Button type="Accept" text="Accept"/>
                <Button type="Reject" text="Reject"/>
            </OverflowToolbar>
        </f:footer>
    </f:DynamicPage>
</mvc:View>
```

We create the master view using `sap.f.DynamicPage`. The page consists of a list with all products.

webapp/view/App.view.xml [MODIFY]

```
<mvc:View
    displayBlock="true"
    height="100%"
    xmlns="sap.f"
    xmlns:mvc="sap.ui.core.mvc">
    <FlexibleColumnLayout id="flexibleColumnLayout" backgroundDesign="Solid">
        <beginColumnPages>
            <mvc:XMLView id="beginView"
viewName="sap.ui.demo.fiori2.view.Master"/>
        </beginColumnPages>
    </FlexibleColumnLayout>
</mvc:View>
```

We add the master view in `FlexibleColumnLayout's beginColumnPages` aggregation.

webapp/controller/Master.controller.js [NEW]

```
sap.ui.define([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    'sap/ui/model/Sorter',
    'sap/m/MessageBox'
], function (JSONModel, Controller, Filter, FilterOperator, Sorter, MessageBox) {
    "use strict";
```

```
    return Controller.extend("sap.ui.demo.fiori2.controller.Master", {
        onInit: function () {
            this.oView = this.getView();
            this._bDescendingSort = false;
            this.oProductsTable = this.oView.byId("productsTable");
        },

        onSearch: function (oEvent) {
            var oTableSearchState = [],
                sQuery = oEvent.getParameter("query");

            if (sQuery && sQuery.length > 0) {
                oTableSearchState = [new Filter("Name", FilterOperator.Contains,
sQuery)];
            }

            this.oProductsTable.getBinding("items").filter(oTableSearchState,
"Application");
        },

        onAdd: function () {
            MessageBox.information("This functionality is not ready yet.",
{title: "Aw, Snap!"});
        },

        onSort: function () {
            this._bDescendingSort = !this._bDescendingSort;
            var oBinding = this.oProductsTable.getBinding("items"),
                oSorter = new Sorter("Name", this._bDescendingSort);

            oBinding.sort(oSorter);
        }
    });
});
```

We create the master controller that provides a basic search and sort functionality for the products listed in the master page.

Step 4: Adding a Detail Page

In this step, we add an empty detail page.

Preview

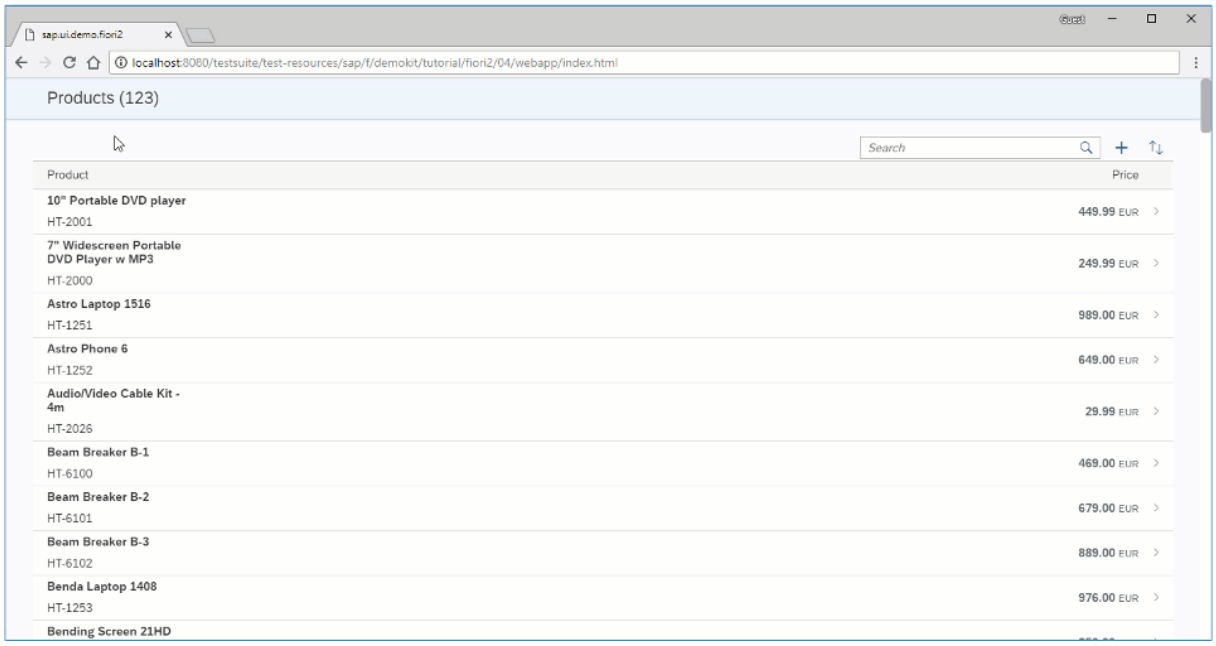

Figure 151: Master Page with Empty Detail Page

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 4.

webapp/view/Detail.view.xml [NEW]

```
<mvc:View
    xmlns:mvc="sap.ui.core.mvc">
</mvc:View>
```

First, we create a blank detail page.

webapp/view/App.view.xml [MODIFY]

```
<mvc:View
```

```
    displayBlock="true"
    height="100%"
    xmlns="sap.f"
    xmlns:mvc="sap.ui.core.mvc">
    <FlexibleColumnLayout id="flexibleColumnLayout" backgroundDesign="Solid">
        <beginColumnPages>
            <mvc:XMLView id="beginView"
viewName="sap.ui.demo.fiori2.view.Master"/>
        </beginColumnPages>
        <midColumnPages>
            <mvc:XMLView id="detailView"
viewName="sap.ui.demo.fiori2.view.Detail"/>
        </midColumnPages>
    </FlexibleColumnLayout>
</mvc:View>
```

We add the detail page in `FlexibleColumnLayout's midColumnPages` aggregation in the `App.view.xml` file. This way the detail page will be displayed in the middle column.

webapp/view/Master.view.xml [MODIFY]

```
        ...
        <!-- DynamicPage Content -->
                    ...
                    ...
                    <items>
                        <ColumnListItem type="Navigation"
press=".onListItemPress">
                            <cells>
                                <ObjectIdentifier title="{products>Name}"
text="{products>ProductId}"/>
                                <ObjectNumber
                                    number="{
                                        parts:[
                                            {path:'products>Price'},
                                            {path:'products>CurrencyCode'}
                                        ],
                                        type: 'sap.ui.model.type.Currency',
                                        formatOptions: {showMeasure: false}
                                    }"
                                    unit="{products>CurrencyCode}"/>
                            </cells>
                        </ColumnListItem>
                    </items>
                    ...
```

We add a `press` handler to each `ColumnListItem` in the `Master.view.xml`.

webapp/controller/Master.controller.js [MODIFY]

```
sap.ui.define([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    'sap/ui/model/Sorter',
```

```
    'sap/m/MessageBox',
    'sap/f/library'
], function (JSONModel, Controller, Filter, FilterOperator, Sorter, MessageBox,
fioriLibrary) {
    "use strict";
        ...
        ...
        onSort: function () {
            this._bDescendingSort = !this._bDescendingSort;
            var oBinding = this.oProductsTable.getBinding("items"),
                oSorter = new Sorter("Name", this._bDescendingSort);
            oBinding.sort(oSorter);
        },

        onListItemPress: function () {
            var oFCL = this.oView.getParent().getParent();

            oFCL.setLayout(fioriLibrary.LayoutType.TwoColumnsMidExpanded);
        }
    });
});
```

In the `Master.controller.js`, we attach a `onListItemPress` function to the `press` handler, which changes the `layout` to `TwoColumnsBeginExpanded`. This means that there are going to be two columns, where the first one is larger than the second. For more information on the available layout types, see Types of Layout [page 2290].

Step 5: Using Object Page Layout as a Detail Page

In this step, we add `sap.uxap.ObjectPageLayout` to the detail page to display more information about each product.

The `ObjectPageLayout` control provides a layout that allows apps to easily display information related to a business object.

As of version 1.52, the control can have the same dynamic header that is used in the `sap.f.DynamicPage`. This ensures the availability of all the latest SAP Fiori 2.0 features, such as, having breadcrumbs navigation, navigation actions, and expanding/collapsing the header by tapping/clicking the title area or by selecting the available arrow buttons. For more information, see Object Page Headers [page 2488].

Compared to `sap.f.DynamicPage`, the `sap.uxap.ObjectPageLayout` can provide a more structured page content using an optional anchor bar and block content wrapped in sections and subsections that structure the information. For more information, see Object Page Layout [page 2482].

Preview

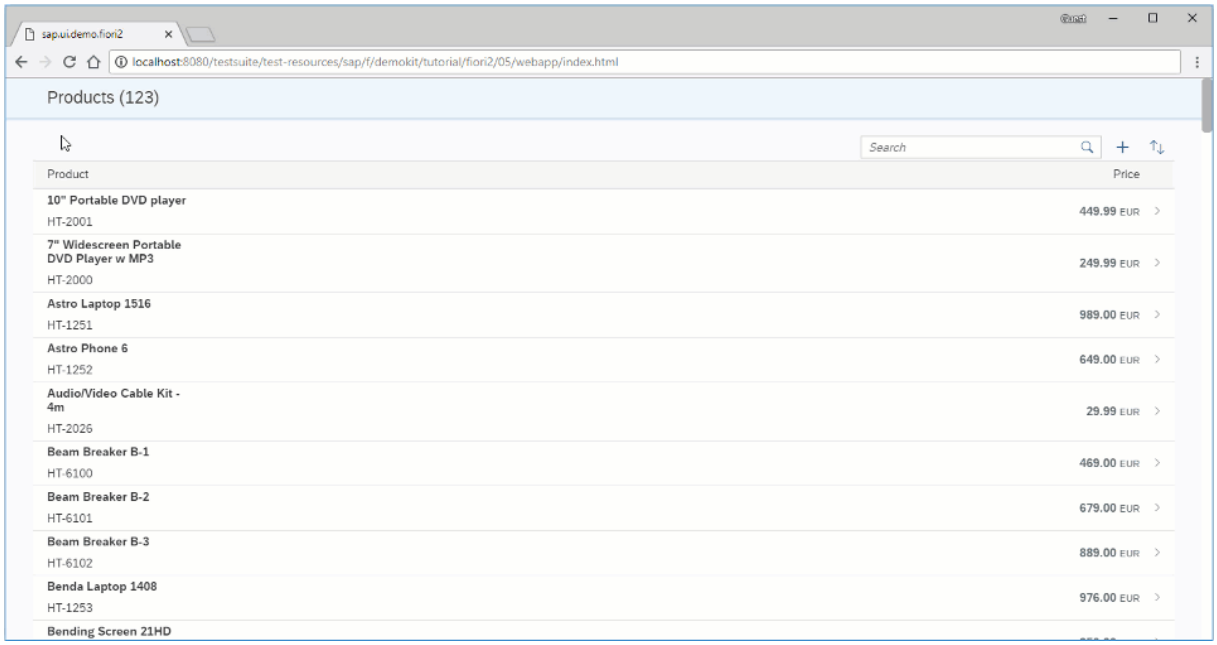

Figure 152: `ObjectPageLayout` with dynamic header for the detail page

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 5.

webapp/manifest.json [MODIFY]

```
{
    "_version": "1.12.0",
    "sap.app": {
        "id": "sap.ui.demo.fiori2",
        "type": "application",
        "applicationVersion": {
            "version": "1.0.0"
        }
    },
    "sap.ui5": {
        "rootView": {
            "viewName": "sap.ui.demo.fiori2.view.App",
            "type": "XML",
            "async": true,
            "id": "fcl"
        },
        "dependencies": {
            "minUI5Version": "1.60.0",
            "libs": {
                "sap.ui.core": {},
                "sap.m": {},
                "sap.f": {},
                "sap.uxap": {}
```

```
            }
        },
        "config": {
            "fullWidth": true
        }
    }
}
```

First, we add the related libraries that we will need to the dependencies in the `manifest.json`.

webapp/view/Detail.view.xml [MODIFY]

```
<mvc:View
    xmlns="sap.uxap"
    xmlns:m="sap.m"
    xmlns:f="sap.f"
    xmlns:form="sap.ui.layout.form"
    xmlns:mvc="sap.ui.core.mvc">
    <ObjectPageLayout
        id="ObjectPageLayout"
        showTitleInHeaderContent="true"
        alwaysShowContentHeader="false"
        preserveHeaderStateOnScroll="false"
        headerContentPinnable="true"
        isChildPage="true"
        upperCaseAnchorBar="false">
    </ObjectPageLayout>
</mvc:View>
```

We add an instance of the `sap.uxap.ObjectPageLayout` control.

webapp/view/Detail.view.xml [MODIFY]

```
<mvc:View
    xmlns="sap.uxap"
    xmlns:m="sap.m"
    xmlns:f="sap.f"
    xmlns:form="sap.ui.layout.form"
    xmlns:mvc="sap.ui.core.mvc">
    <ObjectPageLayout
        id="ObjectPageLayout"
        showTitleInHeaderContent="true"
        alwaysShowContentHeader="false"
        preserveHeaderStateOnScroll="false"
        headerContentPinnable="true"
        isChildPage="true"
        upperCaseAnchorBar="false">
        <headerTitle>
            <ObjectPageDynamicHeaderTitle>
                <actions>
                    <m:ToggleButton
                        text="Edit"
                        type="Emphasized"/>
                    <m:Button
                        text="Delete"
                        type="Transparent"/>
                    <m:Button
```

```
                        text="Copy"
                        type="Transparent"/>
                    <m:Button
                        icon="sap-icon://action"
                        type="Transparent"/>
                </actions>
            </ObjectPageDynamicHeaderTitle>
        </headerTitle>
    </ObjectPageLayout>
</mvc:View>
```

We add the recommended dynamic header with an instance of the `ObjectPageDynamicHeaderTitle` in the `headerTitle` aggregation of the `ObjectPageLayout`. For more information, see Object Page Dynamic Header [page 2494] and Object Page Headers Comparison [page 2497].

webapp/view/Detail.view.xml [MODIFY]

```
        ...
        <headerTitle>
            <ObjectPageDynamicHeaderTitle>
                <actions>
                    <m:ToggleButton
                        text="Edit"
                        type="Emphasized"/>
                    <m:Button
                        text="Delete"
                        type="Transparent"/>
                    <m:Button
                        text="Copy"
                        type="Transparent"/>
                    <m:Button
                        icon="sap-icon://action"
                        type="Transparent"/>
                </actions>
            </ObjectPageDynamicHeaderTitle>
        </headerTitle>
        <headerContent>
            <m:FlexBox wrap="Wrap" fitContainer="true" alignItems="Stretch">
                <f:Avatar
                    displaySize="L"
                    displayShape="Square"
                    class="sapUiTinyMarginEnd">
                </f:Avatar>
                <m:VBox justifyContent="Center" class="sapUiSmallMarginEnd">
                    <m:Label text="Main Category"/>
                </m:VBox>
                <m:VBox justifyContent="Center" class="sapUiSmallMarginEnd">
                    <m:Label text="Subcategory"/>
                </m:VBox>
                <m:VBox justifyContent="Center" class="sapUiSmallMarginEnd">
                    <m:Label text="Price"/>
                </m:VBox>
            </m:FlexBox>
        </headerContent>
    </ObjectPageLayout>
</mvc:View>
```

We add content in the `headerContent` aggregation. We're using `sap.f.Avatar` as the recommended SAP Fiori 2.0 control for displaying images.

webapp/view/Detail.view.xml [MODIFY]

```
        ...
        <headerContent>
            <m:FlexBox wrap="Wrap" fitContainer="true" alignItems="Stretch">
                <f:Avatar
                    displaySize="L"
                    displayShape="Square"
                    class="sapUiTinyMarginEnd">
                </f:Avatar>
                <m:VBox justifyContent="Center" class="sapUiSmallMarginEnd">
                    <m:Label text="Main Category"/>
                </m:VBox>
                <m:VBox justifyContent="Center" class="sapUiSmallMarginEnd">
                    <m:Label text="Subcategory"/>
                </m:VBox>
                <m:VBox justifyContent="Center" class="sapUiSmallMarginEnd">
                    <m:Label text="Price"/>
                </m:VBox>
            </m:FlexBox>
        </headerContent>
        <sections>
            <ObjectPageSection title="General Information">
                <subSections>
                    <ObjectPageSubSection>
                        <blocks>
                            <form:SimpleForm
                                maxContainerCols="2"
                                editable="false"
                                layout="ResponsiveGridLayout"
                                labelSpanL="12"
                                labelSpanM="12"
                                emptySpanL="0"
                                emptySpanM="0"
                                columnsL="1"
                                columnsM="1">
                                <form:content>
                                    <m:Label text="Product ID"/>
                                    <m:Label text="Description"/>
                                    <m:Label text="Supplier"/>
                                </form:content>
                            </form:SimpleForm>
                        </blocks>
                    </ObjectPageSubSection>
                </subSections>
            </ObjectPageSection>

            <ObjectPageSection title="Suppliers">
                <subSections>
                    <ObjectPageSubSection>
                        <blocks>
                            <m:Table
                                id="suppliersTable"
                                items="{path : 'products>/ProductCollectionStats/
Filters/1/values'}">
                                <m:columns>
                                    <m:Column/>
                                </m:columns>
                                <m:items>
                                    <m:ColumnListItem type="Navigation">
                                        <m:cells>
                                            <m:ObjectIdentifier
text="{products>text}"/>
                                        </m:cells>
                                    </m:ColumnListItem>
                                </m:items>
```

```
                            </m:Table>
                        </blocks>
                    </ObjectPageSubSection>
                </subSections>
            </ObjectPageSection>
        </sections>
    </ObjectPageLayout>
</mvc:View>
```

Finally, we add page content in two separate sections with blocks. For more information, see Object Page Blocks [page 2504].

Step 6: Adding a Floating Footer

In this step, we add a floating footer to the detail page.

Preview

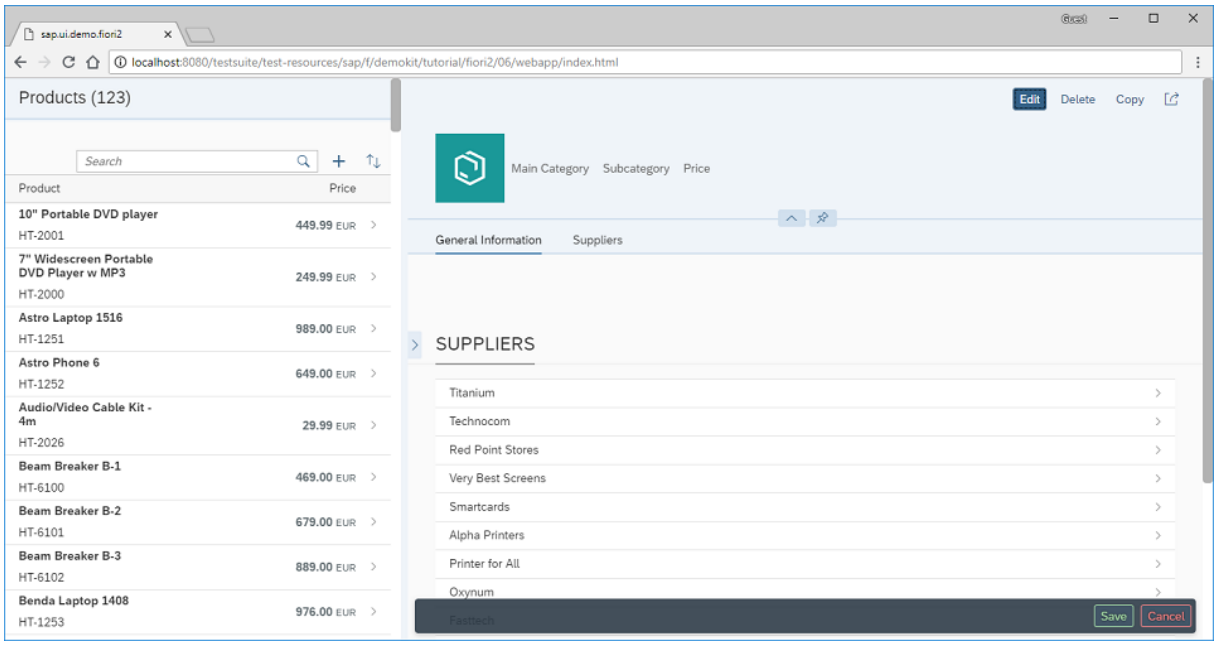

Figure 153: `ObjectPageLayout` with a floating footer

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 6.

webapp/view/App.view.xml [MODIFY]

```
<mvc:View
    displayBlock="true"
    height="100%"
    xmlns="sap.f"
    xmlns:mvc="sap.ui.core.mvc">
    <FlexibleColumnLayout id="flexibleColumnLayout" stateChange="onStateChanged"
backgroundDesign="Solid">
        <beginColumnPages>
            <mvc:XMLView id="beginView"
viewName="sap.ui.demo.fiori2.view.Master"/>
        </beginColumnPages>
        <midColumnPages>
            <mvc:XMLView id="detailView"
viewName="sap.ui.demo.fiori2.view.Detail"/>
        </midColumnPages>
    </FlexibleColumnLayout>
</mvc:View>
```

First, we communicate changes to the layout with the use of the `stateChange` event.

webapp/view/Detail.view.xml [MODIFY]

```
        ...
        </sections>
        <footer>
            <m:OverflowToolbar>
                <m:ToolbarSpacer/>
                <m:Button type="Accept" text="Save"/>
                <m:Button type="Reject" text="Cancel"/>
            </m:OverflowToolbar>
        </footer>
    </ObjectPageLayout>
</mvc:View>
```

We add a footer inside the `sap.uxap.ObjectPageLayout`.

webapp/view/Detail.view.xml [MODIFY]

```
<mvc:View
    controllerName="sap.ui.demo.fiori2.controller.Detail"
    xmlns="sap.uxap"
    xmlns:m="sap.m"
    xmlns:f="sap.f"
    xmlns:form="sap.ui.layout.form"
    xmlns:mvc="sap.ui.core.mvc">
    <ObjectPageLayout
        id="ObjectPageLayout"
        showTitleInHeaderContent="true"
        alwaysShowContentHeader="false"
        preserveHeaderStateOnScroll="false"
        headerContentPinnable="true"
        isChildPage="true"
```

```
        upperCaseAnchorBar="false">
        <headerTitle>
            <ObjectPageDynamicHeaderTitle>
                <actions>
                    <m:ToggleButton
                        text="Edit"
                        type="Emphasized"
                        press=".onEditToggleButtonPress"/>
                    <m:Button
                        text="Delete"
                        type="Transparent"/>
                    <m:Button
                        text="Copy"
                        type="Transparent"/>
                    <m:Button
                        icon="sap-icon://action"
                        type="Transparent"/>
                </actions>
            </ObjectPageDynamicHeaderTitle>
        </headerTitle>
        ...
```

We add a `press` event handler to the *Edit* button.

webapp/controller/Detail.controller.js [NEW]

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function (Controller) {
    "use strict";

    return Controller.extend("sap.ui.demo.fiori2.controller.Detail", {
        onEditToggleButtonPress: function() {
            var oObjectPage = this.getView().byId("ObjectPageLayout"),
                bCurrentShowFooterState = oObjectPage.getShowFooter();

            oObjectPage.setShowFooter(!bCurrentShowFooterState);
        }
    });
});
```

Finally, we create the controller and add a simple function to it to show and hide the footer.

Step 7: Routing

In this step, we utilize the `sap.f.routing.Router`.

Preview

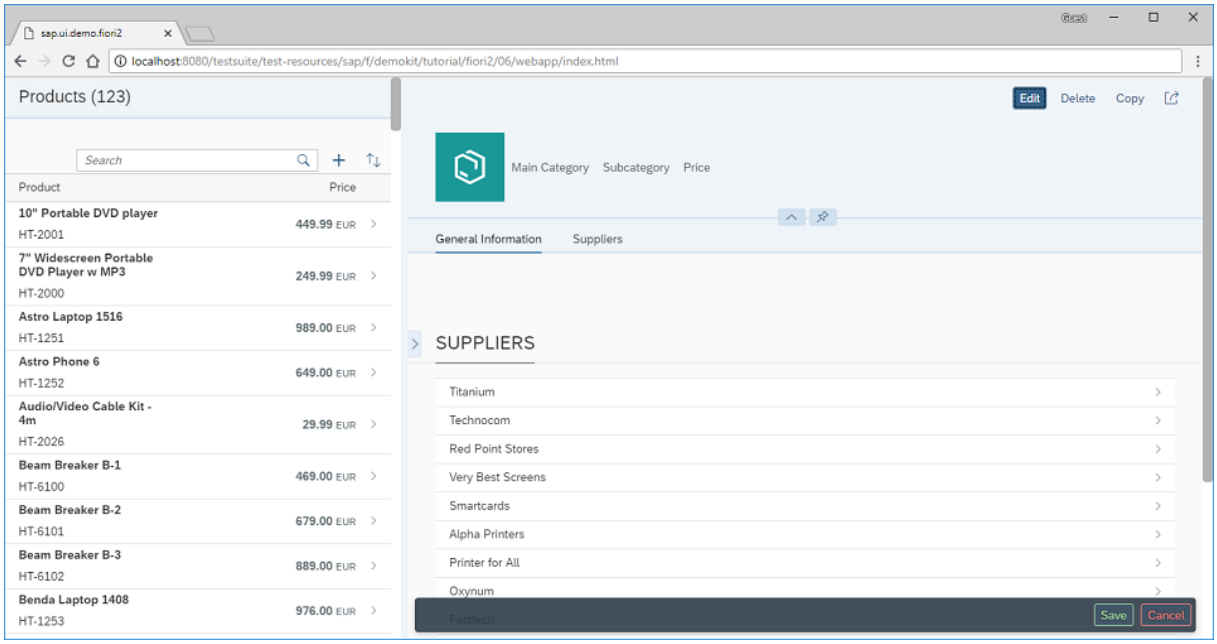

Figure 154: Changing layouts based on the **`sap.f.routing.Router`** (no visual changes to last step)

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 7.

webapp/views/App.view.xml [MODIFY]

```
<mvc:View
    controllerName="sap.ui.demo.fiori2.controller.App"
    displayBlock="true"
    height="100%"
    xmlns="sap.f"
    xmlns:mvc="sap.ui.core.mvc">
    <FlexibleColumnLayout
        id="flexibleColumnLayout"
        stateChange=".onStateChanged"
        backgroundDesign="Solid"
        layout="{/layout}"/>
</mvc:View>
```

We remove the hardcoded `beginColumnPages` and `endColumnPages` aggregations (since the router will add them automatically from now on), and we bind the `layout` property so that it can be changed easily from the controller.

webapp/controller/App.controller.js [NEW]

```
sap.ui.define([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/Controller"
], function (JSONModel, Controller) {
    "use strict";

    return Controller.extend("sap.ui.demo.fiori2.controller.App", {
        onInit: function () {
            this.oOwnerComponent = this.getOwnerComponent();
            this.oRouter = this.oOwnerComponent.getRouter();
            this.oRouter.attachRouteMatched(this.onRouteMatched, this);
        },

        onRouteMatched: function (oEvent) {
            var sRouteName = oEvent.getParameter("name"),
                oArguments = oEvent.getParameter("arguments");

            // Save the current route name
            this.currentRouteName = sRouteName;
            this.currentProduct = oArguments.product;
        },

        onStateChanged: function (oEvent) {
            var bIsNavigationArrow = oEvent.getParameter("isNavigationArrow"),
                sLayout = oEvent.getParameter("layout");

            // Replace the URL with the new layout if a navigation arrow was used
            if (bIsNavigationArrow) {
                this.oRouter.navTo(this.currentRouteName, {layout: sLayout,
product: this.currentProduct}, true);
            }
        },

        onExit: function () {
            this.oRouter.detachRouteMatched(this.onRouteMatched, this);
        }
    });
});
```

We access the router and bind to its `routeMatched` event. For more information, see Router [page 2296].

webapp/controller/Master.controller.js [MODIFY]

```
sap.ui.define([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    'sap/ui/model/Sorter',
    'sap/m/MessageBox',
```

```
    'sap/f/library'
], function (JSONModel, Controller, Filter, FilterOperator, Sorter, MessageBox,
fioriLibrary) {
    "use strict";
    return Controller.extend("sap.ui.demo.fiori2.controller.Master", {
        onInit: function () {
            this.oView = this.getView();
            this._bDescendingSort = false;
            this.oProductsTable = this.oView.byId("productsTable");
            this.oRouter = this.getOwnerComponent().getRouter();
        },
        onSearch: function (oEvent) {
            var oTableSearchState = [],
                sQuery = oEvent.getParameter("query");
            if (sQuery && sQuery.length > 0) {
                oTableSearchState = [new Filter("Name", FilterOperator.Contains,
sQuery)];
            }
            this.oProductsTable.getBinding("items").filter(oTableSearchState,
"Application");
        },
        onAdd: function () {
            MessageBox.show("This functionality is not ready yet.", {
                icon: MessageBox.Icon.INFORMATION,
                title: "Aw, Snap!",
                actions: [MessageBox.Action.OK]
            });
        },
        onSort: function () {
            this._bDescendingSort = !this._bDescendingSort;
            var oBinding = this.oProductsTable.getBinding("items"),
                oSorter = new Sorter("Name", this._bDescendingSort);
            oBinding.sort(oSorter);
        },
        onListItemPress: function (oEvent) {
            var productPath =
oEvent.getSource().getBindingContext("products").getPath(),
                product = productPath.split("/").slice(-1).pop();
            this.oRouter.navTo("detail", {layout:
fioriLibrary.LayoutType.TwoColumnsMidExpanded, product: product});
        }
    });
});
```

We change the event handler for pressing an item from the master view to use the router instead of manually manipulating the `FlexibleColumnLayout` instance. When we call the router's `navTo` method, the router itself will change the `layout` property of the `FlexibleColumnLayout`.

webapp/controller/Detail.controller.js [MODIFY]

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function (Controller) {
    "use strict";
    return Controller.extend("sap.ui.demo.fiori2.controller.Detail", {
        onInit: function () {
            var oOwnerComponent = this.getOwnerComponent();

            this.oRouter = oOwnerComponent.getRouter();
            this.oModel = oOwnerComponent.getModel();
```

```
this.oRouter.getRoute("master").attachPatternMatched(this._onProductMatched,
this);

this.oRouter.getRoute("detail").attachPatternMatched(this._onProductMatched,
this);
        },

        _onProductMatched: function (oEvent) {
            this._product = oEvent.getParameter("arguments").product ||
this._product || "0";
            this.getView().bindElement({
                path: "/ProductCollection/" + this._product,
                model: "products"
            });
        },
        onEditToggleButtonPress: function() {
            var oObjectPage = this.getView().byId("ObjectPageLayout"),
                bCurrentShowFooterState = oObjectPage.getShowFooter();
            oObjectPage.setShowFooter(!bCurrentShowFooterState);
        },

        onExit: function () {

this.oRouter.getRoute("master").detachPatternMatched(this._onProductMatched,
this);

this.oRouter.getRoute("detail").detachPatternMatched(this._onProductMatched,
this);
        }
    });
});
```

We bind the table in the detail view to reflect the currently selected product from the master view.

webapp/Component.js [MODIFY]

```
sap.ui.define([
    'sap/ui/core/UIComponent',
    'sap/ui/model/json/JSONModel',
    'sap/f/library'
], function(UIComponent, JSONModel, fioriLibrary) {
    'use strict';
    return UIComponent.extend('sap.ui.demo.fiori2.Component', {
        metadata: {
            manifest: 'json'
        },
        init: function () {
            var oModel,
                oProductsModel,
                oRouter;
            UIComponent.prototype.init.apply(this, arguments);
            oModel = new JSONModel();
            this.setModel(oModel);
            // set products demo model on this sample
            oProductsModel = new JSONModel(sap.ui.require.toUrl('sap/ui/demo/
mock') + '/products.json');
            oProductsModel.setSizeLimit(1000);
            this.setModel(oProductsModel, 'products');
            oRouter = this.getRouter();
            oRouter.attachBeforeRouteMatched(this._onBeforeRouteMatched, this);
            oRouter.initialize();
        },
```

```
        _onBeforeRouteMatched: function(oEvent) {
            var oModel = this.getModel(),
                sLayout = oEvent.getParameters().arguments.layout;

            // If there is no layout parameter, set a default layout (normally
OneColumn)
            if (!sLayout) {
                sLayout = fioriLibrary.LayoutType.OneColumn;
            }

            oModel.setProperty("/layout", sLayout);
        }
    });
});
```

We initialize the router and bind to its `onBeforeRouteMatched` event, and we introduce a model, which will be used for the layout.

webapp/manifest.json [MODIFY]

```
{
    "_version": "1.12.0",
    "sap.app": {
        "id": "sap.ui.demo.fiori2",
        "type": "application",
        "applicationVersion": {
            "version": "1.0.0"
        }
    },
    "sap.ui5": {
        "rootView": {
            "viewName": "sap.ui.demo.fiori2.view.App",
            "type": "XML",
            "async": true,
            "id": "fcl"
        },
        "dependencies": {
            "minUI5Version": "1.60.0",
            "libs": {

                "sap.m": {},
                "sap.f": {},
                "sap.uxap": {}
            }
        },
        "config": {
            "fullWidth": true
        },
        "routing": {
            "config": {
                "routerClass": "sap.f.routing.Router",
                "viewType": "XML",
                "viewPath": "sap.ui.demo.fiori2.view",
                "controlId": "flexibleColumnLayout",
                "transition": "slide",
                "bypassed": {
                },
                "async": true
            },
            "routes": [
                {
                    "pattern": ":layout:",
```

```
                    "name": "master",
                    "target": [
                        "master",
                        "detail"
                    ]
                },
                {
                    "pattern": "detail/{product}/{layout}",
                    "name": "detail",
                    "target": [
                        "master",
                        "detail"
                    ]
                }
            ],
            "targets": {
                "master": {
                    "viewName": "Master",
                    "controlAggregation": "beginColumnPages"
                },
                "detail": {
                    "viewName": "Detail",
                    "controlAggregation": "midColumnPages"
                }
            }
        }
    }
}
```

Finally, we add the routing configuration in the `manifest.json`.

Step 8: Enhancing the Detail Page

With routing implemented, the model of the detail page is updated for each product. In this step, we enhance the detail page to show information specific for the selected product.

Preview

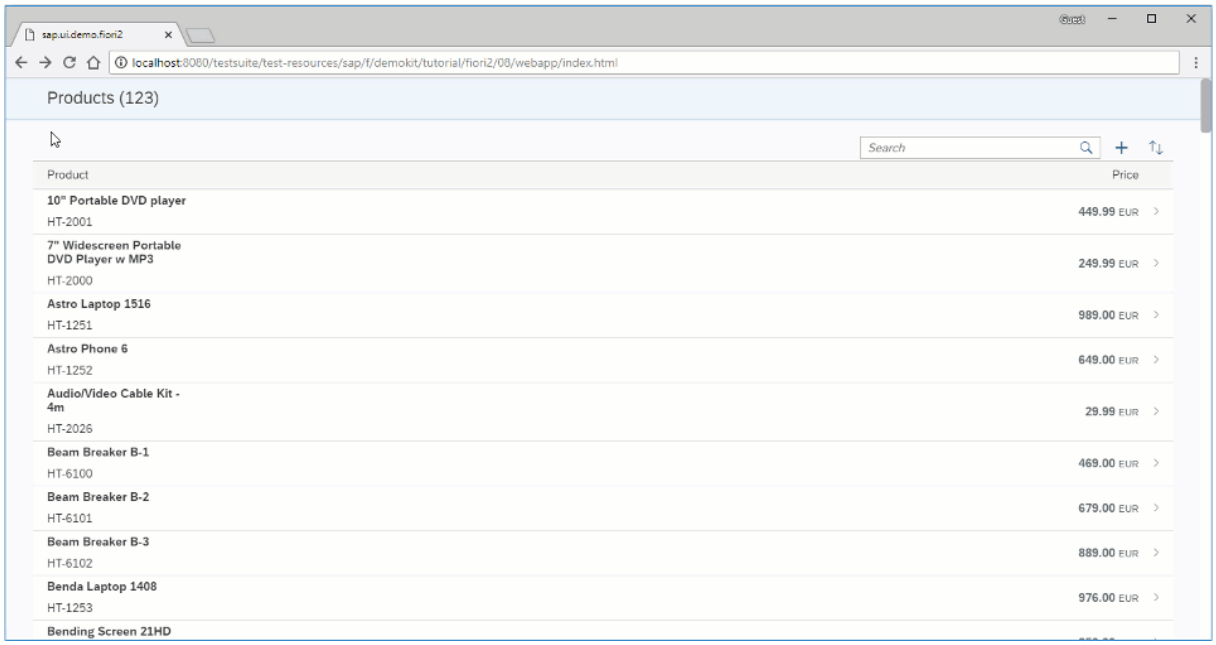

Figure 155: Enhanced detail page displaying information specific to the selected product

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 8.

webapp/view/Detail.view.xml [MODIFY]

```
<mvc:View
    controllerName="sap.ui.demo.fiori2.controller.Detail"
    xmlns="sap.uxap"
    xmlns:m="sap.m"
    xmlns:f="sap.f"
    xmlns:form="sap.ui.layout.form"
    xmlns:mvc="sap.ui.core.mvc">
    <ObjectPageLayout
        id="ObjectPageLayout"
        showTitleInHeaderContent="true"
        alwaysShowContentHeader="false"
        preserveHeaderStateOnScroll="false"
        headerContentPinnable="true"
```

```
        isChildPage="true"
        upperCaseAnchorBar="false">
        <headerTitle>
            <ObjectPageDynamicHeaderTitle>
                <expandedHeading>
                    <m:Title text="{products>Name}" wrapping="true"
class="sapUiSmallMarginEnd"/>
                </expandedHeading>

                <snappedHeading>
                    <m:FlexBox wrap="Wrap" fitContainer="true"
alignItems="Center">
                        <m:FlexBox wrap="NoWrap" fitContainer="true"
alignItems="Center" class="sapUiTinyMarginEnd">
                            <f:Avatar
                                src="https://sapui5.hana.ondemand.com/
{products>ProductPicUrl}"
                                displaySize="S"
                                displayShape="Square"
                                class="sapUiTinyMarginEnd"/>
                            <m:Title text="{products>Name}" wrapping="true"/>
                        </m:FlexBox>
                    </m:FlexBox>
                </snappedHeading>
                <actions>
                ...
```

Using the `expandedHeading` and `snappedHeading` aggregations, we specify different content to be displayed in the title area depending on whether the header is expanded or collapsed.

webapp/view/Detail.view.xml [MODIFY]

```
        ...
        <headerContent>
            <m:FlexBox wrap="Wrap" fitContainer="true" alignItems="Stretch">
                <f:Avatar
                    src="https://sapui5.hana.ondemand.com/
{products>ProductPicUrl}"
                    displaySize="L"
                    displayShape="Square"
                    class="sapUiTinyMarginEnd">
                </f:Avatar>
                <m:VBox justifyContent="Center" class="sapUiSmallMarginEnd">
                    <m:Label text="Main Category"/>
                    <m:Text text="{products>MainCategory}"/>
                </m:VBox>
                <m:VBox justifyContent="Center" class="sapUiSmallMarginEnd">
                    <m:Label text="Subcategory"/>
                    <m:Text text="{products>Category}"/>
                </m:VBox>
                <m:VBox justifyContent="Center" class="sapUiSmallMarginEnd">
                    <m:Label text="Price"/>
                    <m:ObjectNumber number="{products>CurrencyCode}
{products>Price}" emphasized="false"/>
                </m:VBox>
            </m:FlexBox>
        </headerContent>
        ...
```

We adjust the `headerContent` so that the `sap.f.Avatar` displays the specific image of the selected product and the header displays the product's Main Category, Category and Price information, which is provided in the `products.json` we're using.

webapp/view/Detail.view.xml [MODIFY]

```
...
<sections>
    <ObjectPageSection title="General Information">
        <subSections>
            <ObjectPageSubSection>
                <blocks>
                    <form:SimpleForm
                        maxContainerCols="2"
                        editable="false"
                        layout="ResponsiveGridLayout"
                        labelSpanL="12"
                        labelSpanM="12"
                        emptySpanL="0"
                        emptySpanM="0"
                        columnsL="1"
                        columnsM="1">
                        <form:content>
                            <m:Label text="Product ID"/>
                            <m:Text text="{products>ProductId}"/>
                            <m:Label text="Description"/>
                            <m:Text text="{products>Description}"/>
                            <m:Label text="Supplier"/>
                            <m:Text text="{products>SupplierName}"/>
                        </form:content>
                    </form:SimpleForm>
                </blocks>
            </ObjectPageSubSection>
        </subSections>
    </ObjectPageSection>
    ...
```

We adjust the *General Information* section to display Product ID, Description and Supplier of the selected product.

Step 9: Adding a Detail-Detail Page

In this step, we create a detail-detail page using `sap.f.DynamicPage`, which is opened by choosing a supplier from the detail page.

Preview

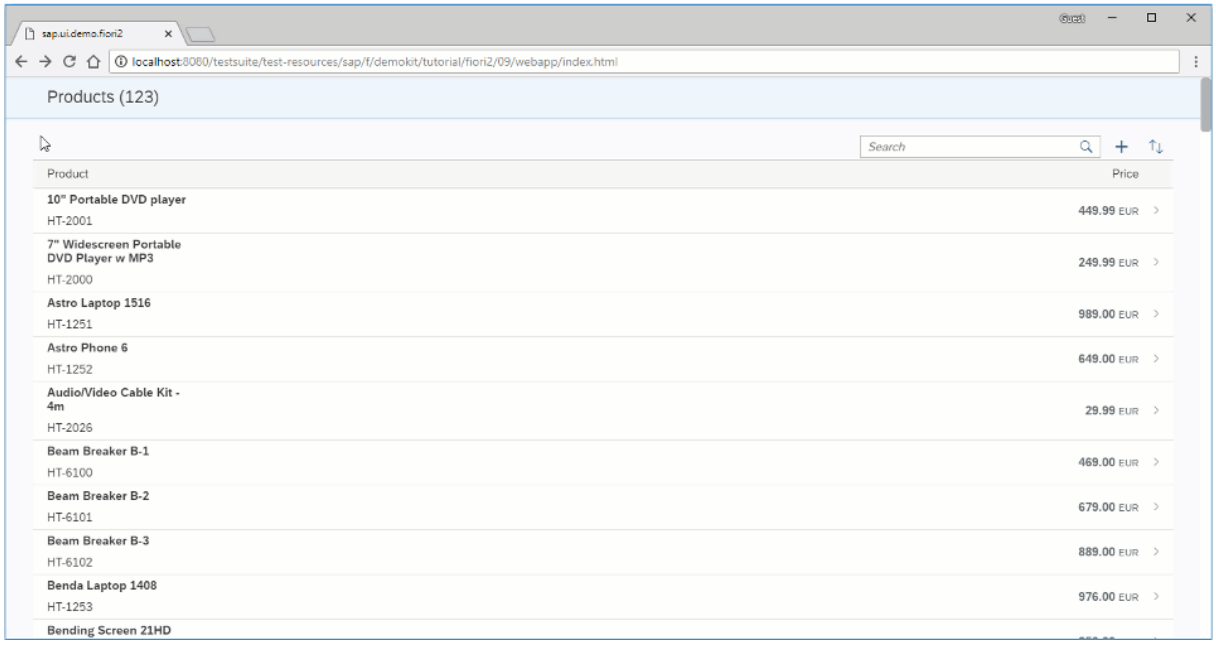

Figure 156: Detail-detail page displaying the name of the selected supplier

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 9.

webapp/view/DetailDetail.view.xml [NEW]

```
<mvc:View
    controllerName="sap.ui.demo.fiori2.controller.DetailDetail"
    xmlns="sap.f"
    xmlns:m="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <DynamicPage toggleHeaderOnTitleClick="false">
        <title>
            <DynamicPageTitle>
                <heading>
                    <m:FlexBox wrap="Wrap" fitContainer="true"
alignItems="Center">
                        <m:Title text="{products>text}" wrapping="true"
class="sapUiTinyMarginEnd"/>
```

```
                    </m:FlexBox>
                </heading>
            </DynamicPageTitle>
        </title>
    </DynamicPage>
</mvc:View>
```

We create a detail-detail page view using `sap.f.DynamicPage` with only a title.

webapp/controller/DetailDetail.controller.js [NEW]

```
sap.ui.define([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/Controller"
], function (JSONModel, Controller) {
    "use strict";

    return Controller.extend("sap.ui.demo.fiori2.controller.DetailDetail", {
        onInit: function () {
            var oOwnerComponent = this.getOwnerComponent();

            this.oRouter = oOwnerComponent.getRouter();
            this.oModel = oOwnerComponent.getModel();

this.oRouter.getRoute("detailDetail").attachPatternMatched(this._onPatternMatch,
this);
        },

        _onPatternMatch: function (oEvent) {
            this._supplier = oEvent.getParameter("arguments").supplier ||
this._supplier || "0";
            this._product = oEvent.getParameter("arguments").product ||
this._product || "0";

            this.getView().bindElement({
                path: "/ProductCollectionStats/Filters/1/values/" +
this._supplier,
                model: "products"
            });
        },

        onExit: function () {

this.oRouter.getRoute("detailDetail").detachPatternMatched(this._onPatternMatch,
this);
        }
    });
});
```

We create the detail-detail page controller.

webapp/manifest.json [MODIFY]

```
            ...
            "routes": [
                {
```

```
                    "pattern": ":layout:",
                    "name": "master",
                    "target": [
                        "master",
                        "detail"
                    ]
                },
                {
                    "pattern": "detail/{product}/{layout}",
                    "name": "detail",
                    "target": [
                        "master",
                        "detail"
                    ]
                },
                {
                    "pattern": "detail/{product}/detailDetail/{supplier}/
{layout}",
                    "name": "detailDetail",
                    "target": [
                        "master",
                        "detail",
                        "detailDetail"
                    ]
                }
            ],
            "targets": {
                "master": {
                    "viewName": "Master",
                    "controlAggregation": "beginColumnPages"
                },
                "detail": {
                    "viewName": "Detail",
                    "controlAggregation": "midColumnPages"
                },
                "detailDetail": {
                    "viewName": "DetailDetail",
                    "controlAggregation": "endColumnPages"
                }
            }
        }
    }
}
```

We add the detail-detail page to our existing routes in the `manifest.json`.

webapp/view/Detail.view.xml [MODIFY]

```
            ...
            <ObjectPageSection title="Suppliers">
                <subSections>
                    <ObjectPageSubSection>
                        <blocks>
                            <m:Table
                                id="suppliersTable"
                                items="{path : 'products>/ProductCollectionStats/
Filters/1/values'}">
                                <m:columns>
                                    <m:Column/>
                                </m:columns>
                                <m:items>
                                    <m:ColumnListItem type="Navigation"
press=".onSupplierPress">
```

```
                                        <m:cells>
                                            <m:ObjectIdentifier
text="{products>text}"/>
                                        </m:cells>
                                    </m:ColumnListItem>
                                </m:items>
                            </m:Table>
                        </blocks>
                    </ObjectPageSubSection>
                </subSections>
            </ObjectPageSection>
        </sections>
        ...
```

We add a `press` event handler for each item in the *SUPPLIERS* table in the detail page.

webapp/controller/Detail.controller.js [MODIFY]

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    'sap/f/library'
], function (Controller, fioriLibrary) {
    "use strict";
    return Controller.extend("sap.ui.demo.fiori2.controller.Detail", {
        onInit: function () {
            var oOwnerComponent = this.getOwnerComponent();
            this.oRouter = oOwnerComponent.getRouter();
            this.oModel = oOwnerComponent.getModel();

this.oRouter.getRoute("master").attachPatternMatched(this._onProductMatched,
this);

this.oRouter.getRoute("detail").attachPatternMatched(this._onProductMatched,
this);

this.oRouter.getRoute("detailDetail").attachPatternMatched(this._onProductMatched
, this);
        },
        onSupplierPress: function (oEvent) {
            var supplierPath =
oEvent.getSource().getBindingContext("products").getPath(),
                supplier = supplierPath.split("/").slice(-1).pop();

            this.oRouter.navTo("detailDetail", {layout:
fioriLibrary.LayoutType.ThreeColumnsMidExpanded, supplier: supplier, product:
this._product});
        },
        _onProductMatched: function (oEvent) {
        ...
```

We add an `onSupplierPress` function in the detail page controller in order to pass the data for the selected supplier and navigate to the detail-detail page.

webapp/controller/App.controller.js [MODIFY]

```
        ...
```

```
        onRouteMatched: function (oEvent) {
            var sRouteName = oEvent.getParameter("name"),
                oArguments = oEvent.getParameter("arguments");
            // Save the current route name
            this.currentRouteName = sRouteName;
            this.currentProduct = oArguments.product;
            this.currentSupplier = oArguments.supplier;
        },
        onStateChanged: function (oEvent) {
            var bIsNavigationArrow = oEvent.getParameter("isNavigationArrow"),
                sLayout = oEvent.getParameter("layout");
            // Replace the URL with the new layout if a navigation arrow was used
            if (bIsNavigationArrow) {
                this.oRouter.navTo(this.currentRouteName, {layout: sLayout,
product: this.currentProduct, supplier: this.currentSupplier}, true);
            }
        },
        onExit: function () {
            this.oRouter.detachRouteMatched(this.onRouteMatched, this);
        }
    });
});
```

Finally, we pass data for the supplier in the detail-detail page.

Step 10: Adding More Pages

In this step, we create an additional page that is displayed in a separate fullscreen column.

Preview

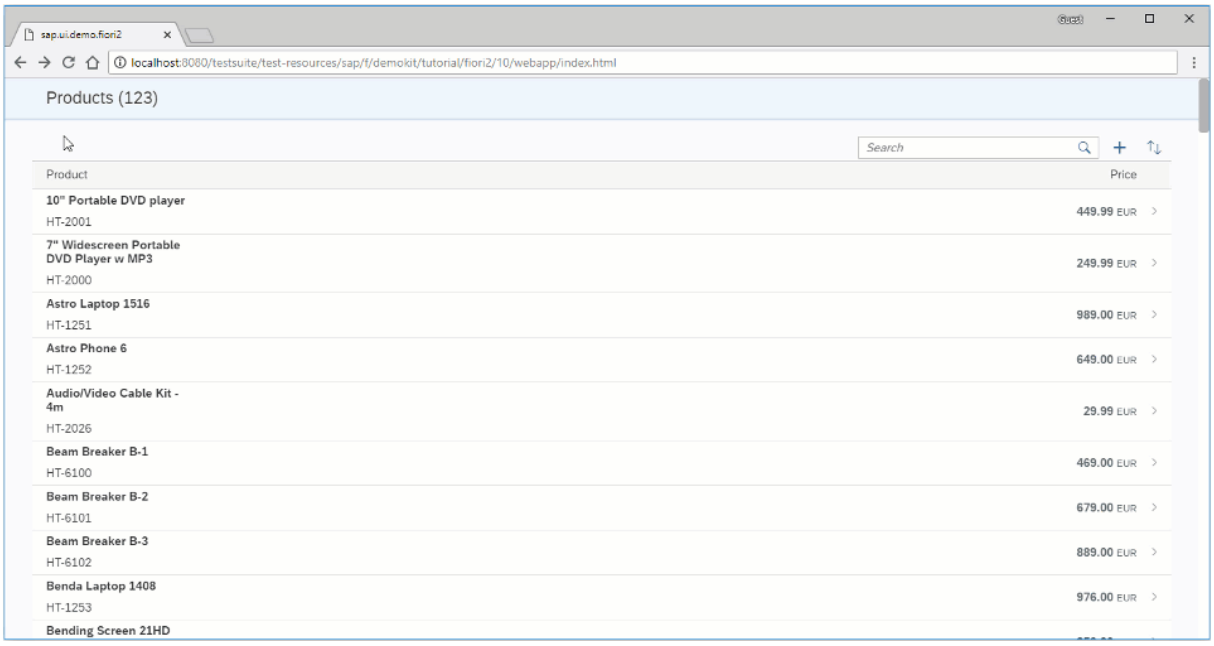

Figure 157: Additional page displayed in a separate fullscreen column

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 10.

webapp/view/AboutPage.view.xml [NEW]

```
<mvc:View
    xmlns="sap.m"
    xmlns:f="sap.f"
    xmlns:mvc="sap.ui.core.mvc">
    <f:DynamicPage toggleHeaderOnTitleClick="false">
        <!-- DynamicPage Title -->
        <f:title>
            <f:DynamicPageTitle>
                <f:heading>
                    <Title text="About supplier"/>
                </f:heading>
            </f:DynamicPageTitle>
        </f:title>
    </f:DynamicPage>
</mvc:View>
```

We create a simple additional page view.

webapp/manifest.json [MODIFY]

```
            ...
            "routes": [
                {
                    "pattern": "page2",
                    "name": "page2",
                    "target": "page2",
                    "layout": "EndColumnFullScreen"
                },
                {
                    "pattern": ":layout:",
                    "name": "master",
                    "target": [
                        "master",
                        "detail"
                    ]
                },
                {
                    "pattern": "detail/{product}/{layout}",
                    "name": "detail",
                    "target": [
                        "master",
                        "detail"
                    ]
                },
                {
                    "pattern": "detail/{product}/detailDetail/{supplier}/
{layout}",
                    "name": "detailDetail",
                    "target": [
                        "master",
```

```
                        "detail",
                        "detailDetail"
                    ]
                }
            ],
            "targets": {
                "master": {
                    "viewName": "Master",
                    "controlAggregation": "beginColumnPages"
                },
                "detail": {
                    "viewName": "Detail",
                    "controlAggregation": "midColumnPages"
                },
                "detailDetail": {
                    "viewName": "DetailDetail",
                    "controlAggregation": "endColumnPages"
                },
                "page2": {
                    "viewName": "AboutPage",
                    "controlAggregation": "endColumnPages"
                }
            }
        }
    }
}
```

Similar to the previous step, we add the additional page view to our existing routes in the `manifest.json`.

webapp/view/DetailDetail.view.xml [MODIFY]

```
<mvc:View
    controllerName="sap.ui.demo.fiori2.controller.DetailDetail"
    xmlns="sap.f"
    xmlns:m="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <DynamicPage toggleHeaderOnTitleClick="false">
        <title>
            <DynamicPageTitle>
                <heading>
                    <m:FlexBox wrap="Wrap" fitContainer="true"
alignItems="Center">
                        <m:Title text="{products>text}" wrapping="true"
class="sapUiTinyMarginEnd"/>
                    </m:FlexBox>
                </heading>
            </DynamicPageTitle>
        </title>
        <content>
            <m:Link text="Navigate to next page…" press=".handleAboutPress"/>
        </content>
    </DynamicPage>
</mvc:View>
```

We add a link in the detail-detail page with a `press` event handler.

webapp/controller/DetailDetail.controller.js [MODIFY]

```
sap.ui.define([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/Controller",
    'sap/f/library'
], function (JSONModel, Controller, fioriLibrary) {
    "use strict";
    return Controller.extend("sap.ui.demo.fiori2.controller.DetailDetail", {
        onInit: function () {
            var oOwnerComponent = this.getOwnerComponent();
            this.oRouter = oOwnerComponent.getRouter();
            this.oModel = oOwnerComponent.getModel();

this.oRouter.getRoute("detailDetail").attachPatternMatched(this._onPatternMatch,
this);
        },
        handleAboutPress: function () {
            this.oRouter.navTo("page2", {layout:
fioriLibrary.LayoutType.EndColumnFullScreen});
        },
        _onPatternMatch: function (oEvent) {
        ...
```

Finally, we add a `handleAboutPress` function in the detail-detail page controller to navigate to the additional page without passing any data this time.

Step 11: Using the Flexible Column Layout Semantic Helper

In this step, we use the `sap.f.FlexibleColumnLayoutSemanticHelper` class to implement the recommended UX patterns for layout changes in the app.

`FlexibleColumnLayout` gives you the freedom to implement any app logic that involves changing the layout (showing/hiding columns) as a result of the user's actions. However, there are certain UX patterns that are considered as optimal and are recommended for SAP Fiori 2.0 apps. The `FlexibleColumnLayoutSemanticHelper` class helps you implement them by giving you tips about what layout to display when.

> **i** Note
>
> Using this class is NOT mandatory in order to build an app with the `FlexibleColumnLayout`, but makes it easier to achieve the optimal UX recommended in the SAP Fiori 2.0 design guidelines.

For more information, see Flexible Column Layout Semantic Helper [page 2294].

Preview

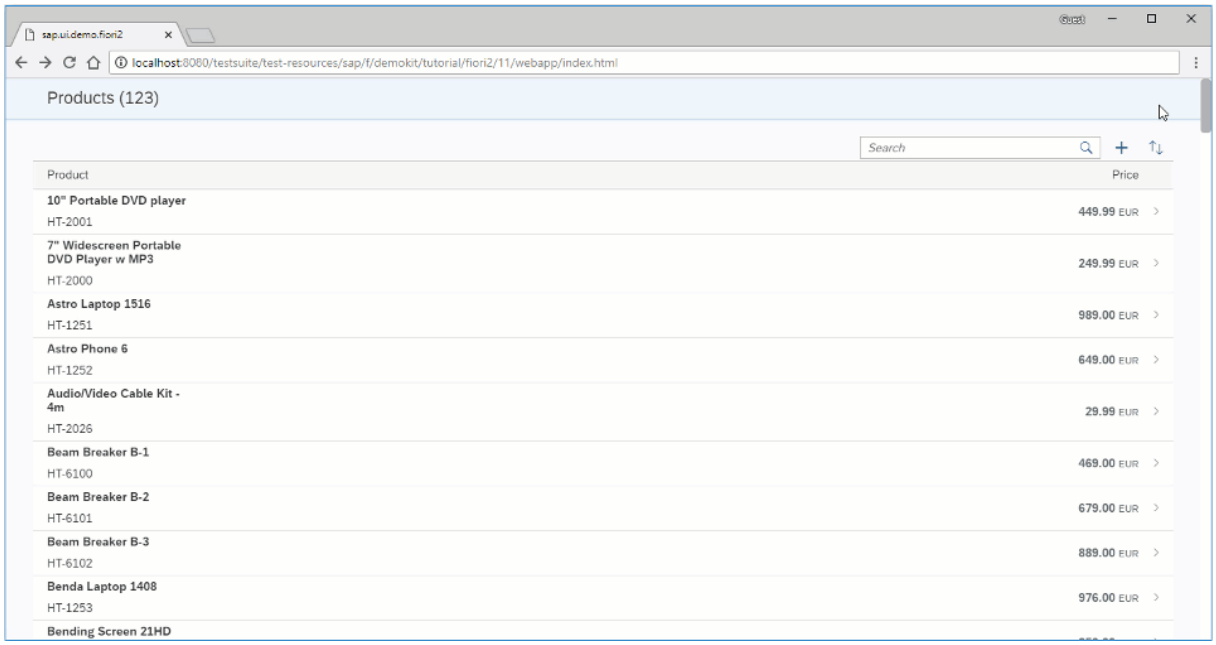

Figure 158: Master-detail-detail pattern using `sap.f.FlexibleColumnLayoutSemanticHelper`

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 11.

webapp/Component.js [MODIFY]

```
sap.ui.define([
    'sap/ui/core/UIComponent',
    'sap/ui/model/json/JSONModel',
    'sap/f/FlexibleColumnLayoutSemanticHelper',
    'sap/f/library'
], function(UIComponent, JSONModel, FlexibleColumnLayoutSemanticHelper,
fioriLibrary) {
    'use strict';
    return UIComponent.extend('sap.ui.demo.fiori2.Component', {
        metadata: {
            manifest: 'json'
        },
        init: function () {
            var oModel,
                oProductsModel,
                oRouter;
            UIComponent.prototype.init.apply(this, arguments);
            oModel = new JSONModel();
            this.setModel(oModel);
            // set products demo model on this sample
            oProductsModel = new JSONModel(sap.ui.require.toUrl('sap/ui/demo/
mock') + '/products.json');
            oProductsModel.setSizeLimit(1000);
```

```
            this.setModel(oProductsModel, 'products');
            oRouter = this.getRouter();
            oRouter.attachBeforeRouteMatched(this._onBeforeRouteMatched, this);
            oRouter.initialize();
        },
        getHelper: function () {
            return this._getFcl().then(function(oFCL) {
                var oSettings = {
                    defaultTwoColumnLayoutType:
fioriLibrary.LayoutType.TwoColumnsMidExpanded,
                    defaultThreeColumnLayoutType:
fioriLibrary.LayoutType.ThreeColumnsMidExpanded
                };
                return (FlexibleColumnLayoutSemanticHelper.getInstanceFor(oFCL,
oSettings));
            });
        },
        _onBeforeRouteMatched: function(oEvent) {
            var oModel = this.getModel(),
                sLayout = oEvent.getParameters().arguments.layout,
                oNextUIState;
            // If there is no layout parameter, query for the default level 0
layout (normally OneColumn)
            if (!sLayout) {
                this.getHelper().then(function(oHelper) {
                    oNextUIState = oHelper.getNextUIState(0);
                    oModel.setProperty("/layout", oNextUIState.layout);
                });
                return;
            }
            oModel.setProperty("/layout", sLayout);
        },

        _getFcl: function () {
            return new Promise(function(resolve, reject) {
                var oFCL = this.getRootControl().byId('flexibleColumnLayout');
                if (!oFCL) {
                    this.getRootControl().attachAfterInit(function(oEvent) {
                        resolve(oEvent.getSource().byId('flexibleColumnLayout'));
                    }, this);
                    return;
                }
                resolve(oFCL);

            }.bind(this));
        }
    });
});
```

First, we add a `getHelper` function in the `Component.js` file in order to pass the default `sap.f.FlexibleColumnLayout` parameters.

webapp/view/Detail.view.xml [MODIFY]

```
                ...
                <snappedHeading>
                    <m:FlexBox wrap="Wrap" fitContainer="true"
alignItems="Center">
                        <m:FlexBox wrap="NoWrap" fitContainer="true"
alignItems="Center" class="sapUiTinyMarginEnd">
                            <f:Avatar
                                src="https://sapui5.hana.ondemand.com/
{products>ProductPicUrl}"
```

```
                                displaySize="S"
                                displayShape="Square"
                                class="sapUiTinyMarginEnd"/>
                            <m:Title text="{products>Name}" wrapping="true"/>
                        </m:FlexBox>
                    </m:FlexBox>
                </snappedHeading>
                <navigationActions>
                    <m:OverflowToolbarButton
                        type="Transparent"
                        icon="sap-icon://full-screen"
                        press=".handleFullScreen"
                        tooltip="Enter Full Screen Mode"
                        visible="{= ${/actionButtonsInfo/midColumn/fullScreen} !
== null }"/>
                    <m:OverflowToolbarButton
                        type="Transparent"
                        icon="sap-icon://exit-full-screen"
                        press=".handleExitFullScreen"
                        tooltip="Exit Full Screen Mode"
                        visible="{= ${/actionButtonsInfo/midColumn/
exitFullScreen} !== null }"/>
                    <m:OverflowToolbarButton
                        type="Transparent"
                        icon="sap-icon://decline"
                        press=".handleClose"
                        tooltip="Close column"
                        visible="{= ${/actionButtonsInfo/midColumn/closeColumn} !
== null }"/>
                </navigationActions>
                <actions>
                    <m:ToggleButton
                        text="Edit"
                        type="Emphasized"
                        press=".onEditToggleButtonPress"/>
                    <m:Button
                        text="Delete"
                        type="Transparent"/>
                    <m:Button
                        text="Copy"
                        type="Transparent"/>
                    <m:Button
                        icon="sap-icon://action"
                        type="Transparent"/>
                </actions>
            </ObjectPageDynamicHeaderTitle>
        </headerTitle>
        ...
```

We add navigation actions for entering and exiting fullscreen and closing the column for the detail page.

webapp/controller/Detail.controller.js [MODIFY]

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function (Controller) {
    "use strict";
    return Controller.extend("sap.ui.demo.fiori2.controller.Detail", {
        onInit: function () {
            this.oOwnerComponent = this.getOwnerComponent();
            this.oRouter = this.oOwnerComponent.getRouter();
            this.oModel = this.oOwnerComponent.getModel();
```

```
this.oRouter.getRoute("master").attachPatternMatched(this._onProductMatched,
this);

this.oRouter.getRoute("detail").attachPatternMatched(this._onProductMatched,
this);

this.oRouter.getRoute("detailDetail").attachPatternMatched(this._onProductMatched
, this);
        },
        onSupplierPress: function (oEvent) {
            var supplierPath =
oEvent.getSource().getBindingContext("products").getPath(),
                supplier = supplierPath.split("/").slice(-1).pop(),
                oNextUIState;

            this.oOwnerComponent.getHelper().then(function (oHelper) {
                oNextUIState = oHelper.getNextUIState(2);
                this.oRouter.navTo("detailDetail", {
                    layout: oNextUIState.layout,
                    supplier: supplier,
                    product: this._product
                });
            }.bind(this));
        },
        _onProductMatched: function (oEvent) {
            this._product = oEvent.getParameter("arguments").product ||
this._product || "0";
            this.getView().bindElement({
                path: "/ProductCollection/" + this._product,
                model: "products"
            });
        },
        onEditToggleButtonPress: function() {
            var oObjectPage = this.getView().byId("ObjectPageLayout"),
                bCurrentShowFooterState = oObjectPage.getShowFooter();
            oObjectPage.setShowFooter(!bCurrentShowFooterState);
        },
        handleFullScreen: function () {
            var sNextLayout = this.oModel.getProperty("/actionButtonsInfo/
midColumn/fullScreen");
            this.oRouter.navTo("detail", {layout: sNextLayout, product:
this._product});
        },

        handleExitFullScreen: function () {
            var sNextLayout = this.oModel.getProperty("/actionButtonsInfo/
midColumn/exitFullScreen");
            this.oRouter.navTo("detail", {layout: sNextLayout, product:
this._product});
        },

        handleClose: function () {
            var sNextLayout = this.oModel.getProperty("/actionButtonsInfo/
midColumn/closeColumn");
            this.oRouter.navTo("master", {layout: sNextLayout});
        },
        onExit: function () {

this.oRouter.getRoute("master").detachPatternMatched(this._onProductMatched,
this);

this.oRouter.getRoute("detail").detachPatternMatched(this._onProductMatched,
this);
        }
    });
});
```

We create the handlers needed for the navigation actions.

webapp/view/DetailDetail.view.xml [MODIFY]

```
<mvc:View
    controllerName="sap.ui.demo.fiori2.controller.DetailDetail"
    xmlns="sap.f"
    xmlns:m="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <DynamicPage toggleHeaderOnTitleClick="false">
        <title>
            <DynamicPageTitle>
                <heading>
                    <m:FlexBox wrap="Wrap" fitContainer="true"
alignItems="Center">
                        <m:Title text="{products>text}" wrapping="true"
class="sapUiTinyMarginEnd"/>
                    </m:FlexBox>
                </heading>
                <navigationActions>
                    <m:OverflowToolbarButton
                        type="Transparent"
                        icon="sap-icon://full-screen"
                        press=".handleFullScreen"
                        tooltip="Enter Full Screen Mode"
                        visible="{= ${/actionButtonsInfo/endColumn/fullScreen} !
== null }"/>
                    <m:OverflowToolbarButton
                        type="Transparent"
                        icon="sap-icon://exit-full-screen"
                        press=".handleExitFullScreen"
                        tooltip="Exit Full Screen Mode"
                        visible="{= ${/actionButtonsInfo/endColumn/
exitFullScreen} !== null }"/>
                    <m:OverflowToolbarButton
                        type="Transparent"
                        icon="sap-icon://decline"
                        press=".handleClose"
                        tooltip="Close column"
                        visible="{= ${/actionButtonsInfo/endColumn/closeColumn} !
== null }"/>
                </navigationActions>
            </DynamicPageTitle>
        </title>
        <content>
            <m:Link text="Navigate to next page…" press=".handleAboutPress"/>
        </content>
    </DynamicPage>
</mvc:View>
```

Again, we add navigation actions for entering and exiting fullscreen and closing the column for the detail-detail page.

webapp/controller/DetailDetail.controller.js [MODIFY]

```
sap.ui.define([
    "sap/ui/model/json/JSONModel",
```

```
    "sap/ui/core/mvc/Controller"
], function (JSONModel, Controller) {
    "use strict";
    return Controller.extend("sap.ui.demo.fiori2.controller.DetailDetail", {
        onInit: function () {
            this.oOwnerComponent = this.getOwnerComponent();
            this.oRouter = this.oOwnerComponent.getRouter();
            this.oModel = this.oOwnerComponent.getModel();

this.oRouter.getRoute("detailDetail").attachPatternMatched(this._onPatternMatch,
this);
        },
        handleAboutPress: function () {
            var oNextUIState;
            this.oOwnerComponent.getHelper().then(function (oHelper) {
                oNextUIState = oHelper.getNextUIState(3);
                this.oRouter.navTo("page2", {layout: oNextUIState.layout});
            }.bind(this));
        },
        _onPatternMatch: function (oEvent) {
            this._supplier = oEvent.getParameter("arguments").supplier ||
this._supplier || "0";
            this._product = oEvent.getParameter("arguments").product ||
this._product || "0";
            this.getView().bindElement({
                path: "/ProductCollectionStats/Filters/1/values/" +
this._supplier,
                model: "products"
            });
        },
        handleFullScreen: function () {
            var sNextLayout = this.oModel.getProperty("/actionButtonsInfo/
endColumn/fullScreen");
            this.oRouter.navTo("detailDetail", {layout: sNextLayout, product:
this._product, supplier: this._supplier});
        },

        handleExitFullScreen: function () {
            var sNextLayout = this.oModel.getProperty("/actionButtonsInfo/
endColumn/exitFullScreen");
            this.oRouter.navTo("detailDetail", {layout: sNextLayout, product:
this._product, supplier: this._supplier});
        },

        handleClose: function () {
            var sNextLayout = this.oModel.getProperty("/actionButtonsInfo/
endColumn/closeColumn");
            this.oRouter.navTo("detail", {layout: sNextLayout, product:
this._product});
        },
        onExit: function () {

this.oRouter.getRoute("detailDetail").detachPatternMatched(this._onPatternMatch,
this);
        }
    });
});
```

And respectively, we create the handlers needed for the navigation actions in the detail-detail controller.

webapp/controller/Master.controller.js [MODIFY]

```
sap.ui.define([
```

```
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/Filter",
    "sap/ui/model/FilterOperator",
    'sap/ui/model/Sorter',
    'sap/m/MessageBox'
], function (JSONModel, Controller, Filter, FilterOperator, Sorter, MessageBox) {
    "use strict";
    return Controller.extend("sap.ui.demo.fiori2.controller.Master", {
        onInit: function () {
            this.oView = this.getView();
            this._bDescendingSort = false;
            this.oProductsTable = this.oView.byId("productsTable");
            this.oRouter = this.getOwnerComponent().getRouter();
        },
        onSearch: function (oEvent) {
            var oTableSearchState = [],
                sQuery = oEvent.getParameter("query");
            if (sQuery && sQuery.length > 0) {
                oTableSearchState = [new Filter("Name", FilterOperator.Contains,
sQuery)];
            }
            this.oProductsTable.getBinding("items").filter(oTableSearchState,
"Application");
        },
        onAdd: function () {
            MessageBox.information("This functionality is not ready yet.",
{title: "Aw, Snap!"});
        },
        onSort: function () {
            this._bDescendingSort = !this._bDescendingSort;
            var oBinding = this.oProductsTable.getBinding("items"),
                oSorter = new Sorter("Name", this._bDescendingSort);
            oBinding.sort(oSorter);
        },
        onListItemPress: function (oEvent) {
            var productPath =
oEvent.getSource().getBindingContext("products").getPath(),
                product = productPath.split("/").slice(-1).pop(),
                oNextUIState;
            this.getOwnerComponent().getHelper().then(function (oHelper) {
                oNextUIState = oHelper.getNextUIState(1);
                this.oRouter.navTo("detail", {
                    layout: oNextUIState.layout,
                    product: product
                });
            }.bind(this));
        }
    });
});
```

We get the next layout from the semantic helper rather than hard coding them ourselves.

webapp/controller/App.controller.js [MODIFY]

```
sap.ui.define([
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/mvc/Controller"
], function (JSONModel, Controller) {
    "use strict";
    return Controller.extend("sap.ui.demo.fiori2.controller.App", {
        onInit: function () {
            this.oOwnerComponent = this.getOwnerComponent();
```

```
            this.oRouter = this.oOwnerComponent.getRouter();
            this.oRouter.attachRouteMatched(this.onRouteMatched, this);
        },
        onRouteMatched: function (oEvent) {
            var sRouteName = oEvent.getParameter("name"),
                oArguments = oEvent.getParameter("arguments");
            this._updateUIElements();
            // Save the current route name
            this.currentRouteName = sRouteName;
            this.currentProduct = oArguments.product;
            this.currentSupplier = oArguments.supplier;
        },
        onStateChanged: function (oEvent) {
            var bIsNavigationArrow = oEvent.getParameter("isNavigationArrow"),
                sLayout = oEvent.getParameter("layout");
            this._updateUIElements();
            // Replace the URL with the new layout if a navigation arrow was used
            if (bIsNavigationArrow) {
                this.oRouter.navTo(this.currentRouteName, {layout: sLayout,
product: this.currentProduct, supplier: this.currentSupplier}, true);
            }
        },
        // Update the close/fullscreen buttons visibility
        _updateUIElements: function () {
            var oModel = this.oOwnerComponent.getModel(),
                oUIState;
            this.oOwnerComponent.getHelper().then(function(oHelper) {
                oUIState = oHelper.getCurrentUIState();
                oModel.setData(oUIState);
            });
        },
        onExit: function () {
            this.oRouter.detachRouteMatched(this.onRouteMatched, this);
            this.oRouter.detachBeforeRouteMatched(this.onBeforeRouteMatched,
this);
        }
    });
});
```

Finally, we create a function in the `App.controller.js` to update the visibility of the master, detail, and detail-detail pages.

Step 12: Starting with Two Columns

In this step, we set up the app to start with an initial layout of two columns.

By default, the `FlexibleColumnLayout` starts off with one column. If your use case requires it, you can set the initial layout to start with two columns. The user can still navigate to a single-column layout by closing the detail page from the navigation actions or a three-column layout by selecting an item from the detail page.

Preview

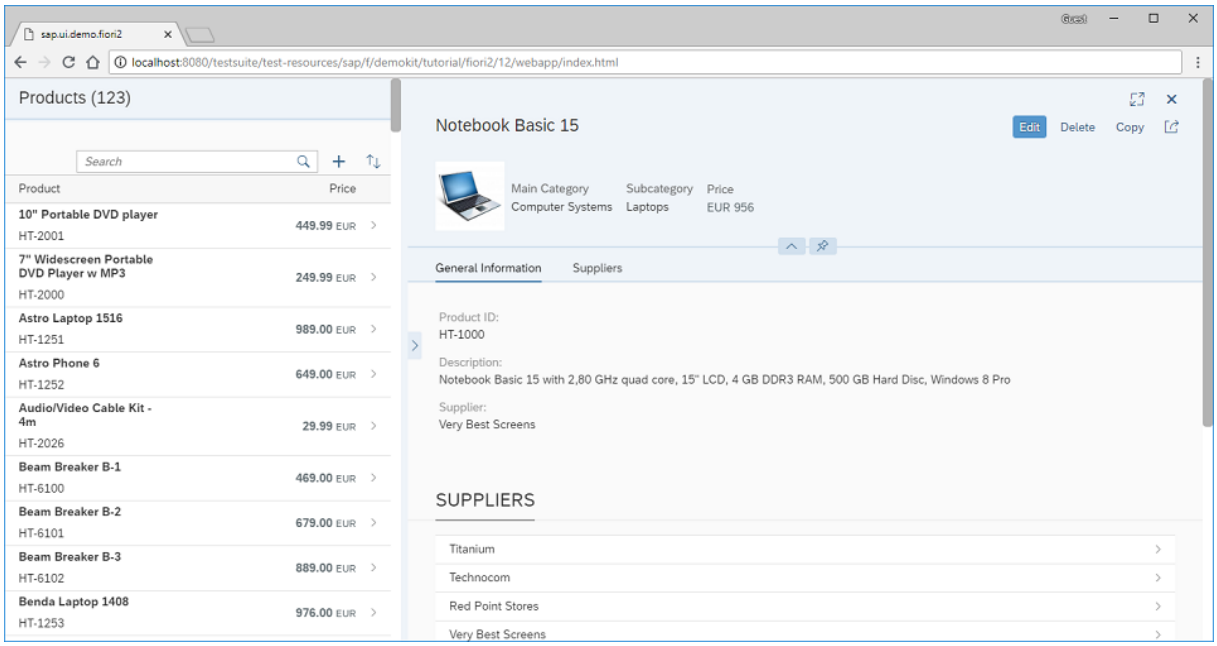

Figure 159: Initial layout with two columns

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 12.

webapp/Component.js [MODIFY]

```
        ...
        getHelper: function () {
            return this._getFcl().then(function(oFCL) {
                var oSettings = {
                    defaultTwoColumnLayoutType:
fioriLibrary.LayoutType.TwoColumnsMidExpanded,
                    defaultThreeColumnLayoutType:
fioriLibrary.LayoutType.ThreeColumnsMidExpanded,
                    initialColumnsCount: 2
                };
                return (FlexibleColumnLayoutSemanticHelper.getInstanceFor(oFCL,
oSettings));
            });
        },
        ...
```

We set the `initialColumnsCount` parameter of the `getHelper` method to `2`.

Step 13: Setting the Master-Detail Pattern

In this step, we set up the app to follow the master-detail pattern.

Apps using the master-detail pattern operate with a layout divided into two separate areas - a master list area and a details area. The master list area displays the items available to the user and the details area displays the details for an item that is selected in the master list. If your use case requires it, you can set the `FlexibleColumnLayout` to use a maximum of two columns. For more information, see the SAP Fiori Design Guidelines.

Preview

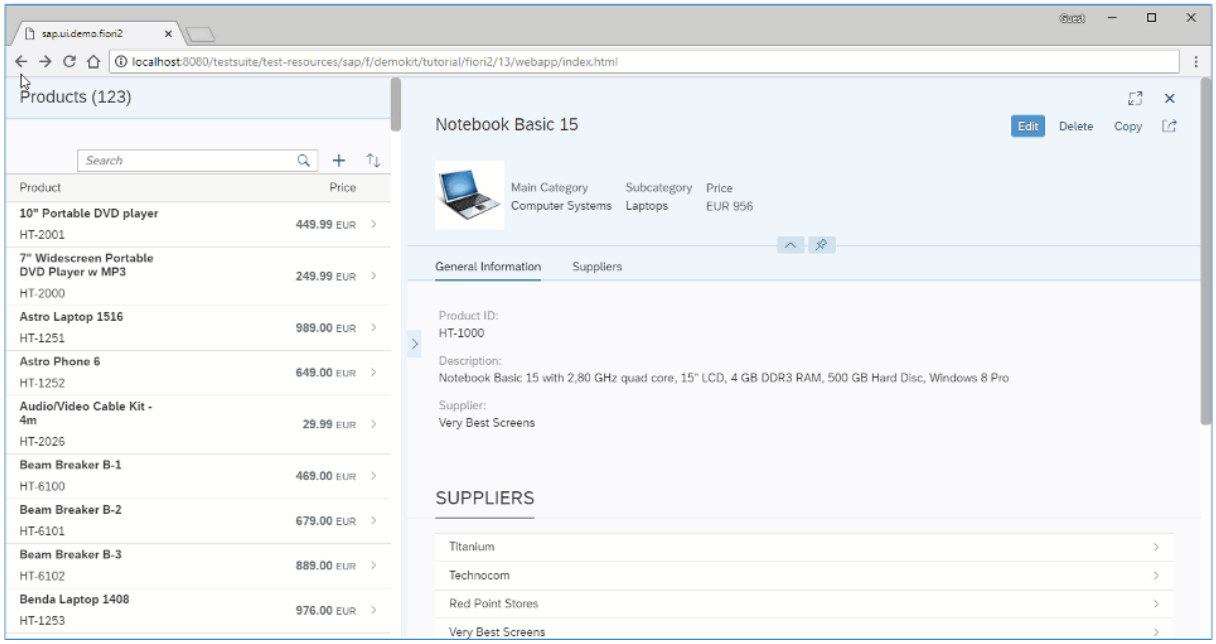

Figure 160: Master-detail pattern with `FlexibleColumnLayout`

Coding

You can view and download all files at SAP Fiori 2.0 App - Step 13.

webapp/Component.js [MODIFY]

```
        ...
        getHelper: function () {
            return this._getFcl().then(function(oFCL) {
                var oSettings = {
                    defaultTwoColumnLayoutType:
fioriLibrary.LayoutType.TwoColumnsMidExpanded,
```

```
                    defaultThreeColumnLayoutType:
fioriLibrary.LayoutType.ThreeColumnsMidExpanded,
                    initialColumnsCount: 2,
                    maxColumnsCount: 2
                };
                return (FlexibleColumnLayoutSemanticHelper.getInstanceFor(oFCL,
oSettings));
            });
        },
        ...
```

We set `maxColumnsCount` parameter of the `getHelper` method to `2`.

Rule Builder Control

In this tutorial you will learn how to embed a rule builder control to manage business rules in your application.

A business rule is a logic that defines some aspect of business and always resolves to either true or false. This logic can be maintained by non-technical users via a simplified rule language and user interface. Thus, business rules allow your application's customers to add their own logic without needing technical customization or coding.

The rule builder control enables business users to create and edit business rules in applications based on SAPUI5. The control defines SAP standard UX for creating business rules in an SAP Fiori application and should be the default UI component for SAP Fiori UI developers to add business rule capabilities.

The `sap.rules.ui` library provides controls to manage business rules. The two main components are:

- `RuleBuilder` – Provides visualization of the rule in the form of a decision table and text rule to simplify the creation and editing of the rule's business logic.
- Expression Language Services – Provides expression language services to support the readability and correctness of business rules.

The visualization provided by the `RuleBuilder` component contains text parts and the expression language services support the end user in creating and editing those text parts.

→ Tip

You do not have to do the tutorial steps sequentially; you can start the tutorial at any step you want. Just download the code, copy it to your workspace and make sure that the application runs by calling the `index.html` file.

You can view and download all the files required for steps 1 and 2 in decision table section at Rule Builder - Guided Decision Table. This is applicable only for decision table rules modeled using rule expression language.

You can view and download all the files required for steps 1 and 2 in text rule section at Rule Builder - Text Rule.

For more information, check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]

Expression Languages

You can model rules using an expression language. There are two expression languages supported by the rule builder:

- **Expression Language 1.0 (Rule Expression Language)**: Expression language 1.0 enable users to define business decision logic in simple readable syntax. This is the default language supported by the rule builder. A typical rule condition in expression language 1.0 is as shown below:
  `customer_name of the customer is equal to 'John`
- **Expression Language 2.0 (DMN SFEEL)**: Expression language 2.0 or DMN SFEEL is a subset of the Friendly Enough Expression Language (FEEL), provides a standard syntax for rule conditions, and reduces ambiguities while modeling a rule. A typical rule condition in expression language 2.0 is as shown below:
  `customer.customer name MATCHES 'John'`
  Key features of expression language 2.0 include:
  - **Autosuggest list** is a suggestion dropdown menu that lets you select the required element of the rule expression. You do not have to type the rule expression in the corresponding fields.
  - You can also type the rule expression in the field and select the corresponding vocabulary elements from the autosuggest list. Using free flow typing, you can also edit and delete the tokens in a rule expressions.

    > **Example**
    >
    > In the following rule expression:
    >
    > DO1.Equipment = 'Laptop' *AND* DO2.Date = 'Dec 3, 2020'
    >
    > - If the cursor is placed between *DO* and *1*, then all the data objects starting with DO are listed in the autosuggest list. Similarly, according to the cursor position, the corresponding data object or attribute name is listed.
    > - To change a date or timestamp value, edit the value in the *Fixed Value* field of the autosuggest list.
    > - If the cursor is placed before the attribute name *Equipment*, then the attribute name is deleted.
    > - If the cursor is placed in between or before the data object name, *DO1*, then both the data object and attribute name, *DO1.Equipment*, is deleted.
  - Expression language 2.0 supports the use of **vocabulary rules**. The rules which can be used in a rule expression are called vocabulary rules. The result returned by the vocabulary rule can be consumed in a rule expression.

The following are the objects for each expression language:

Expression Language	Expression Language Object
Expression language 1.0	ExpressionLanguage
Expression language 2.0	AstExpressionLanguage

> **Note**
>
> You can migrate your projects from expression language 1.0 to expression language 2.0 using the business rules API. For more information, see SAP Cloud Platform Business Rules. You should manually change

the expression language object to `AstExpressionLanguage` to load the migrated content in expression language 2.0.

Prerequisites

You should already have some general knowledge about SAPUI5 application development and the SAP rules framework.

For more information, see the documentation for the SAP HANA Rules Framework on the SAP Help Portal at https://help.sap.com/viewer/p/SAP_HANA_RULES_FRAMEWORK.

This tutorial uses a mock server to provide the required data. Before proceeding with this tutorial, ensure that you are familiar with the concepts introduced in the following tutorials:

- Walkthrough [page 69], specifically Step 27: Mock Server Configuration [page 139]
- Mock Server [page 432]

> **i Note**
>
> Alternatively, you can use a properly configured backend system with the following implemented OData services:
>
> - Rules OData service – provides rule resources to create and edit all the elements required for rules.
> - Vocabulary OData service – provides vocabulary data resources.
>
> For more information, see the OData API reference on the SAP Help Portal at https://help.sap.com/doc/12167f8dbcc54650b47644c140fa0d0b/DEV/en-US/Rules_odata_api_index.html.

We will use a simple HTML page that will serve as a single-page application. There we will define the content of this page, which will include the meta tags, a script tag to load the SAPUI5 `sap.rules.ui` libraries, and the `RuleBuilder` control with data from the mock server.

File Structure

For this tutorial, you will be creating a folder with the following files:

- **<FolderName>** (folder)
  - `Component.js`
  - `index.html`
  - `Page.controller.js`
  - `Page.view.xml`
  - localService (folder)
    - rule (folder)
      - mockdata (folder)
      - `metadata.xml`
      - `responses.json`

- vocabulary (folder)
  - mockdata (folder)
  - `metadata.xml`

Decision Table

Create a business logic by defining the conditions in decision table, which is associated with the expression language.

Features

Refresh Data Object

The refresh data object feature reads the attributes of the data object and automatically fetches the predefined result attributes.

Cut/Copy/Paste

- The *Copy* option is used to duplicate the specific row and it can be inserted in any other row of the decision table using *Paste* option.
- The *Cut* option is used to remove the specific row and that can also be inserted in any other row of the decision table using paste option.

Hit Policy

For a decision table rule, you can specify how the rule engine should fetch the result. The two types of hit policies are first match and all match:

- *First Match*: The rule engine fetches the first occurrence that matches the condition and the corresponding result is returned.
- *All Match*: The rule engine fetches all the occurrences that matches the condition and returns them as result.

Access Modes

The access modes provided to the value in the decision table settings should be either `Editable` or `Hidden`.

- The hidden access sets that default value to all the rows corresponding to the attribute in decision table, where the result column gets hidden. The default value is `mandatory`.
- The editable access sets that default value to the new row, which is created after the settings are applied. The default value is `optional`.

Basic and Advanced Mode

- The *Basic* mode is explained as follows
  - It provides the easy way of creating a rule in decision table, which is applicable only for conditions column.

- If the operator is not set in the settings of the decision table, then the operator list will be provided as a dropdown in the popover of the decision table row. Once the operator is selected, you will get the input field option to set the value for the column.
- Different options are provided to set the values based on the selected data type such as, input field for **string** and **number**, date picker for **date**, dropdown for **boolean**, time picker for **time**.
- If the expression is given in the input field for the data type string and number, then the expression can be validated by clicking on the popover itself. If the data is wrong, then the expression will not be taken and the popover gets closed.
- If the data type is string, the value can be entered without quotes.
- **Exist in** operator is not supported.
- Auto suggestion is limited to advance mode which is not available in the basic mode.

- The *Advanced* mode enables you to create a rule with the auto suggestion and value help feature, which is applicable only for result column.

> **i** Note
>
> Basic and advanced modes are applicable only for decision table rules that are modeled using rule expression language.

Step 1: Creating an Initial Rule Control

In this step, we embed a rule control into an application view.

The `RuleBuilder` component is a container of rules controls, which can bundle different visualization means. Currently the only visualization available is the decision table. The `RuleBuilder` defines common rules UI consumption patterns and APIs to be followed by UI developers.

In this example, we create a decision table, which will use the guided input mode.

> **i** Note
>
> Guided input mode is predefined in the settings for each condition column in the data for this tutorial.

Coding

You can view and download all files at Rule Builder - Guided Decision Table.

Page.view.xml

```
<mvc:View
        xmlns:mvc="sap.ui.core.mvc"
        displayBlock="true"
        xmlns="sap.m"
```

```
        controllerName="sap.rules.ui.sample.GuidedDecisionTable.Page"
        viewName="sap.rules.ui.sample.GuidedDecisionTable.Page.view"
        xmlns:rules="sap.rules.ui">
    <Button id="editButton" press="handleEditButton" text="Edit"/>
    <rules:RuleBuilder id="ruleBuilder" types="DecisionTable" editable="false"/>
</mvc:View>
```

We add to the view a `RuleBuilder` control of type `DecisionTable`.

The above code will place and render the `RuleBuilder` control in the view without data. Initially, the control is set to Display mode, which means that the decision table cannot be edited. The *Edit* button allows users to change the mode for editing.

Now we need to connect the `ExpressionLanguage` object association to the `RuleBuilder`, which we do in the next step, and then the control loads its data via the OData model.

Step 2: Associating the Expression Language

Expression languages provide the required services for rule authoring, rule visualization, and rule content validation. The services provided by the expression language object include expression validations, expression parsing, auto-complete suggestions, retrieval of expression metadata and tokens, and performing runtime services such as fetching data objects, outputs, and so on.

The vocabulary OData model and the binding context path for the specific vocabulary are mandatory input for the expression language.

The expression language objects are an association of the `RuleBuilder` object, and it can be associated with multiple `RuleBuilder` objects.

Preview

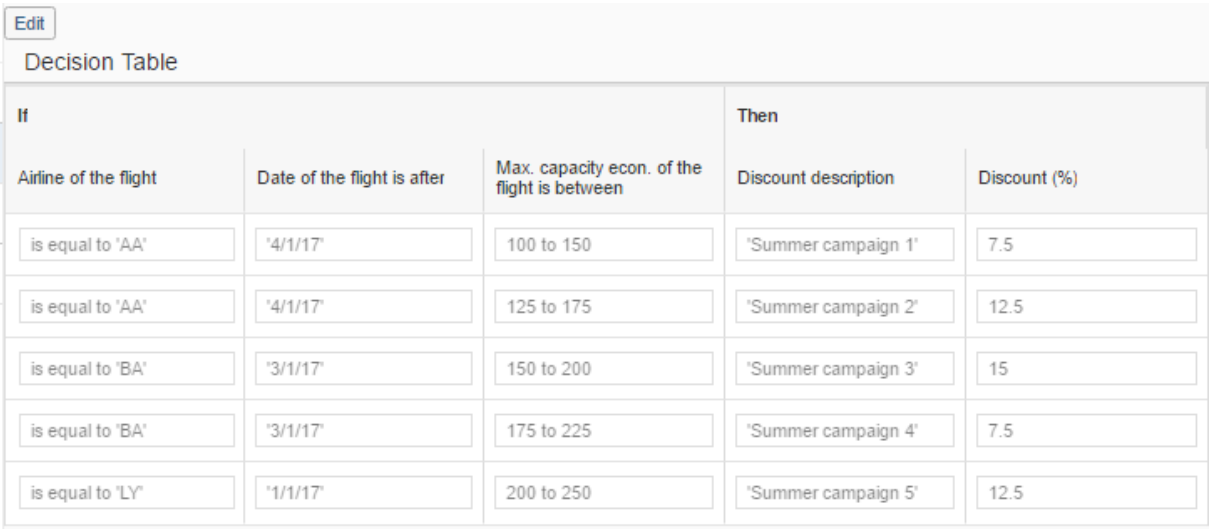

Figure 161: Decision Table with Guided Input

Coding

You can view and download all files at Rule Builder - Guided Decision Table. This is applicable only for rule expression language.

Before you begin, customize the `Page.controller.js` as per your requirements.

- Set the expression language object:
  For rule expression language:

  ```
  oExpressionLanguage = new sap.rules.ui.services.ExpressionLanguage();
  oRuleBuilder.setExpressionLanguage(oExpressionLanguage);
  ```

  For DMN SFEEL:

  ```
  oAstExpressionLanguage = new sap.rules.ui.services.AstExpressionLanguage();
  oRuleBuilder.setAstExpressionLanguage(oAstExpressionLanguage);
  ```

- Ensure that you have set the data before setting the vocabulary model for the expression language as shown:

  ```
  oExpressionLanguage.setData(data);
  oExpressionLanguage.setModel(that.oVocabularyModel);
  ```

Page.controller.js

```
sap.ui.define([
    'jquery.sap.global',
    'sap/ui/core/mvc/Controller',
    'sap/ui/model/odata/v2/ODataModel',
    'sap/rules/ui/services/ExpressionLanguage',   //For DMN SFEEL language, use
'AstExpressionLanguage'.
    'sap/ui/core/util/MockServer',
    'sap/m/MessageToast'
], function (jQuery, Controller, ODataModel, ExpressionLanguage, MockServer,
MessageToast) {    //For DMN SFEEL language, use 'AstExpressionLanguage' instead
of 'ExpressionLanguage'.
    "use strict";
    return Controller.extend("sap.rules.ui.sample.GuidedDecisionTable.Page", {
        onInit: function () {
            sap.ui.getCore().applyTheme("sap_belize");
            // apply compact density for desktop, the cozy design otherwise
            this.getView().addStyleClass(sap.ui.Device.system.desktop ?
"sapUiSizeCompact" : "sapUiSizeCozy");
            var mPath =
jQuery.sap.getModulePath("sap.rules.ui.sample.GuidedDecisionTable", "/");

            // Initialize Expression Language services
            this.oVocabularyMockServer = new MockServer({rootUri: "/sap/opu/
odata/SAP/vocabulary_srv/"});
            this.oVocabularyMockServer.simulate(
                mPath + "localService/vocabulary/metadata.xml",
                {'sMockdataBaseUrl': mPath + "localService/vocabulary/mockdata/"}
            );
            this.oVocabularyMockServer.start();
            this.oVocabularyModel = new ODataModel("/sap/opu/odata/SAP/
vocabulary_srv/");
            this.oExpressionLanguage = new ExpressionLanguage();                //
For DMN SFEEL, use 'new AstExpressionLanguage();'.
            this.oExpressionLanguage.setModel(this.oVocabularyModel);
            this.oExpressionLanguage.setBindingContextPath("/
Vocabularies('FA163E38C6481EE785F409DCAD583D43')");
```

```

RULE_SRV/"});
            this.oRuleMockServer.simulate(
                mPath + "localService/rule/metadata.xml",
                {'sMockdataBaseUrl': mPath + "localService/rule/mockdata/"}
            );
            var aRequests = this.loadRequests(mPath);
            this.oRuleMockServer.setRequests(aRequests);
            this.oRuleMockServer.start();
            this.oRuleModel = new ODataModel({
                serviceUrl: "/sap/opu/odata/SAP/RULE_SRV/",
                defaultBindingMode: sap.ui.model.BindingMode.TwoWay
            });
            var oRuleBuilder = this.byId("ruleBuilder");
            oRuleBuilder.setModel(this.oRuleModel);
            oRuleBuilder.setExpressionLanguage(this.oExpressionLanguage);
            oRuleBuilder.setBindingContextPath("/
Rules(Id='FA163E38C6481EE785F409DCAD583D43',Version='000001')");
        },
        handleEditButton: function () {
            var oEditButton = this.byId("editButton");
            var oRuleBuilder = this.byId("ruleBuilder");
            var bEdit = (oEditButton.getText() === "Edit");
            oRuleBuilder.setEditable(bEdit);
            oEditButton.setText(bEdit ? "Display" : "Edit");
        },
        onAfterRendering: function () {
            // Line actions are not supported in this demo
            var oRuleBuilder = this.byId("ruleBuilder");
            var oDecisionTable = oRuleBuilder.getAggregation("_rule");
            var oToolbar = oDecisionTable.getAggregation("_toolbar");
            var arrContent = oToolbar.getContent();
            for (var i = 0; i < arrContent.length; i++) {
                if (arrContent[i].getMetadata().getName() === "sap.m.Button") {

arrContent[i].detachPress(arrContent[i].mEventRegistry.press[0].fFunction,
arrContent[i].mEventRegistry.press[0].oListner);
                    arrContent[i].attachPress(function (oEvent) {
                            var msg = 'Line action pressed';
                            MessageToast.show(msg);
                        }
                    );
                } else if (arrContent[i].getMetadata().getName() ===
"sap.m.MenuButton") {
                    var oMenu = arrContent[i].getMenu();

oMenu.detachItemSelected(oMenu.mEventRegistry.itemSelected[1].fFunction,
oMenu.mEventRegistry.itemSelected[1].oListner);
                    oMenu.attachItemSelected(function (oEvent) {
                            var msg = 'Line action pressed';
                            MessageToast.show(msg);
                        }
                    );
                }
            }
        },
        loadRequests: function (mPath) {
            // The mock server does not support 1 to 1 navigation.
            // Hence we provide the responses directly by adding custom requests
to the MockServer
            var oRresponses = jQuery.sap.sjax({
                type: "GET",
                url: mPath + "localService/rule/responses.json",
                dataType: "json"
                }
            ).data;
```

```
            var aRequests = this.oRuleMockServer.getRequests();

DecisionTableColumns\?\$skip=0&\$top=\d+&\$expand=Condition%2cResult/;
            var response_2 = this.response_2;
            var fnResponse4 = function (xhr) {
                xhr.respondJSON(200, {
                    "Content-Type": "application/json;charset=utf-8"
                }, oRresponses.response_2);
            }
            aRequests.push({method: sMethod, path: sPath, response:
fnResponse4});
            return aRequests;
        }
    });
});
```

This code adds an expression language object to the view controller, and connects it to the `RuleBuilder` as an association. For the expression language service, this code sets the model and then does all the necessary data binding internally (unlike other SAPUI5 controls where the developer defines the data binding). The data for the expression language is loaded via the vocabulary OData service.

The following are the code modifications that you can make to include additional functionalities:

- For reading specific vocabulary content like data objects, attributes, value help, rules or vocabulary rules, use the following code:

```
this.oVocabularyModel.read(sVocabularyPath, {
                urlParameters: {
                    "$expand": "DataObjects/Associations,DataObjects/
Attributes,ValueSources,Rules"
                },
```

- To set the vocabulary context shown in autosuggestion, use the following code:

```
oExpressionLanguage.setBindingContextPath("/Vocabularies(\'" + <vocabulary
context> + "\')");
```

> **i Note**
>
> Vocabulary context is `ProjectId` by default and all the data objects of the given project are listed in autosuggestion. The possible contexts include `RuleserviceId`, `RuleId` and `ProjectId`.

The code also sets a binding context path on `RuleBuilder` to the specific rule you are currently working on.

Now, when running the application, the decision table will be rendered filled with rule data from the mock server.

> **i Note**
>
> If you are using a back-end system with the relevant implemented OData services, use the following code:

```
sap.ui.define([
    'sap/ui/core/mvc/Controller',
    'sap/ui/model/odata/v2/ODataModel',
    'sap/rules/ui/services/ExpressionLanguage'         //For DMN SFEEL
language, use 'sap/rules/ui/services/AstExpressionLanguage'.
], function ( Controller, ODataModel, ExpressionLanguage) {   //For DMN SFEEL
language, use 'AstExpressionLanguage' instead of 'ExpressionLanguage'.
    "use strict";
    return Controller.extend("mySample.RuleBuilder.Page", {
        onInit: function () {
            // apply compact density for desktop, the cozy design otherwise
            this.getView().addStyleClass(sap.ui.Device.system.desktop ?
"sapUiSizeCompact" : "sapUiSizeCozy");

            // Initialize Expression Language services
            this.oVocabularyModel = new ODataModel("/vocabulary_srv/");
            this.oExpressionLanguage = new ExpressionLanguage();       //For
DMN SFEEL, use 'new AstExpressionLanguage()'.
            this.oExpressionLanguage.setModel(this.oVocabularyModel);
            this.oExpressionLanguage.setBindingContextPath("/
Vocabularies('<your rule ID>')");
            // Initialize the Rule Builder
            this.oRuleModel = new ODataModel({
                serviceUrl: "/sap/opu/odata/SAP/RULE_SRV/",
                defaultBindingMode: sap.ui.model.BindingMode.TwoWay
            });
            var oRuleBuilder = this.byId("ruleBuilder");
            oRuleBuilder.setModel(this.oRuleModel);
            oRuleBuilder.setExpressionLanguage(this.oExpressionLanguage);
            oRuleBuilder.setBindingContextPath("/Rules(Id='<your rule
ID>',Version='000001')");
        },
        handleEditButton: function () {
            var oEditButton = this.byId("editButton");
            var oRuleBuilder = this.byId("ruleBuilder");
            var bEdit = (oEditButton.getText() === "Edit");
            oRuleBuilder.setEditable(bEdit);
            oEditButton.setText(bEdit ? "Display" : "Edit");
        }
    });
});
```

Step 3: Changing the Decision Table Configuration

Decision table has a set of configurations that influence different aspects of the its functionality and the actions that business users can perform. The decision table configuration object has default values, which you can change. Part of the configuration of the decision table can be exposed to the end user via the decision table *Settings* dialog box.

Preview

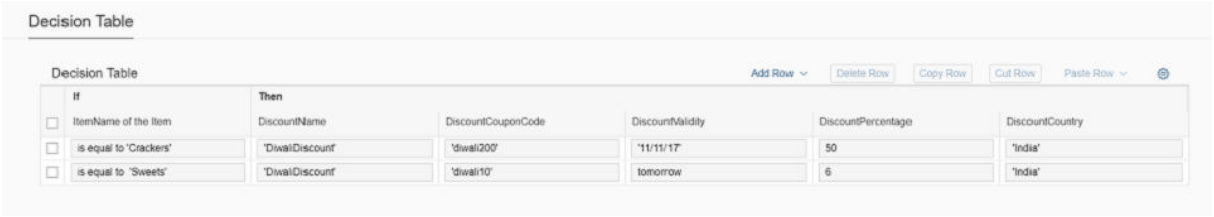

Figure 162: Decision Table with Settings Button

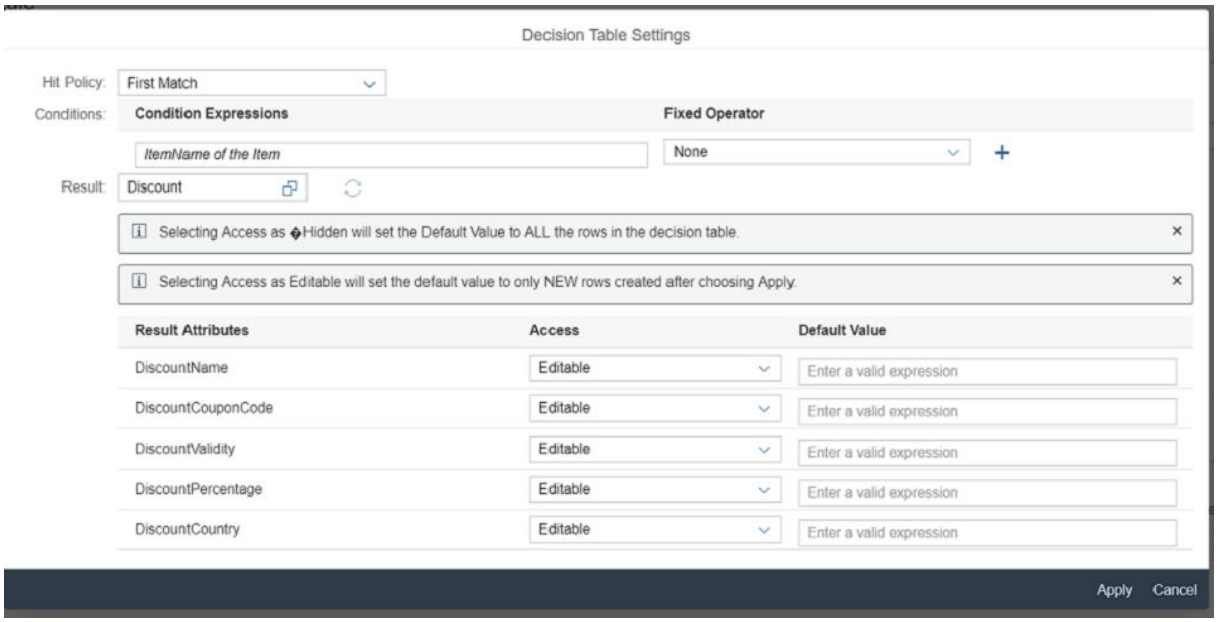

Figure 163: Decision Table Settings Dialog Box

Coding

You can view and download all files at Rule Builder - Guided Decision Table.

> **i Note**
>
> The new code described in this step is not included in the download sample files.

Page.view.xml

```
<mvc:View
        xmlns:mvc="sap.ui.core.mvc"
        displayBlock="true"
        xmlns="sap.m"
        controllerName="sap.rules.ui.sample.GuidedDecisionTable.Page"
        viewName="sap.rules.ui.sample.GuidedDecisionTable.Page.view"
        xmlns:rules="sap.rules.ui">
    <Button id="editButton" press="handleEditButton" text="Edit"/>
    <rules:RuleBuilder id="ruleBuilder" types="DecisionTable" editable="true">
        <rules:decisionTableConfiguration>
        <rules:DecisionTableConfiguration enableSettings="true"/>
        </rules:decisionTableConfiguration>
    </rules:RuleBuilder>
</mvc:View>
```

This code changes the decision table to display and enable the *Settings* icon ( ), which opens the *Settings* dialog box.

> **i** Note
>
> The Cell Format property of the decision table is deprecated from SAPUI5 version 1.52.8. The following is the new property is introduced.
>
> ```
> decisionTableFormat: {
>                     type: "sap.rules.ui.DecisionTableFormat",
>                     defaultValue: sap.rules.ui.DecisionTableFormat.CellFormat
>                 }
> ```
>
> The `enum` for type `sap.rules.ui.DecisionTableFormat` is
>
> ```
> sap.rules.ui.DecisionTableFormat = {
>         CellFormat: "CELLFORMAT",
>         RuleFormat: "RULEFORMAT"
>             };
> ```

The user has to set the the `enum` type to `RuleFormat` for the DecisionTable to be rendered based on rule format.

The value for the rule format is set at the time of rule creation to either basic or advanced mode depending on which the entire rule will be rendered based on basic mode or advanced mode.

Text Rule

Create a business logic by defining conditions (`if`, `else if`) in the form of text that has the result parts (`then`, `else`), which is associated with the rule expression language.

Features

Refresh Data Object

The refresh data object feature reads the attributes of the data object and automatically fetches the predefined result attributes.

Access Modes

The access modes provided to the value in the text rule settings should be either `Editable` or `Hidden`.

- The hidden access sets that default value to the attribute of data object in text rule, where it gets hidden from the text rule. The default value is `mandatory`.
- The editable access sets that default value to the new entries of data object which is created after the settings are applied and new `else` block is created. The default value is `optional`. When the result data object changes, by default all the attributes will have the access mode as `Editable` with no default value.

Operations

You can model a text rule without a result data object too. This type of text rule lets you perform operations on existing data objects or its attributes and is supported only in expression language 2.0. You can also add multiple result operations in a text rule.

> **i** Note
>
> Select *No Default Result* as the text rule result to perform the operations.

To view the list of operations that can be performed on any data object or attribute of your project, press `CTRL` + `SPACE` in the *Then* field of your text rule.

List of Operations:

Operation	Syntax	Input	Description	Example
Update	*UPDATE*(<Target>, <Source>)	`Target Entity`	The target data object or attribute that should be updated as per the value of the `Source Entity` or `Expression`.	*UPDATE*(`Employee_Table.Employee Name`, `Employee.Employee Name`)

Operation	Syntax	Input	Description	Example
		`Source Entity` or `Source Expression`.	The value of the `Target Entity` is updated to the value of the `Source Entity` or the value returned by the `Source Expression`. **i Note** You can also use vocabulary rules as the source expression by selecting it from the autosuggest list.	The data object, `Employee_Table.Employee Name` is updated as per the value of `Employee.Employee Name`.
Append	*APPEND*(<Target>, <Source>)	`Target Entity`	The target data object of type *Table* to which the `Source` has to be appended.	*APPEND*(`FlightTable, Flight`) The data object `Flight` is appended to the data object `FlightTable`.
		`Source Entity` or `Source Expression`	A data object that should be appended to the `Target` data object. Source data object should be of type *Structure* or *Table* or a rule that returns a data object of type *Structure* or *Table*.	

Value Help

While authoring a rule in advanced mode, the auto-complete suggestion list provides the corresponding list of values as value help items along with other auto-complete suggestions.

There are two types of value help:

- Value List : The values are created and maintained in the business rules by adding code and description.
- Service URL Mapping : The values are maintained outside the business rules and you have to configure the managed system to consume the values from external system. For more information on configuring managed system, see Configuring Managed System in SAP Cloud Platform Business Rules.

i Note

- The value list link is provided with the suggestions, only if the attribute is of type value help.
- The value help dialog can also be consumed by pressing **f4** while authoring a rule.
- To change the value help while authoring the rule, you can also click the value help attribute which opens the value help dialog.

- In the following example, the ID of an equipment is an attribute of type value help. While authoring the rule, the value help is provided in the suggestion which has the value list with descriptions as shown in the table. The value can be selected from the list and consumed in the rule.

```
If
        ID of an Equipment is equal to 'E001'
        Then
        Order
```

Table 10: Value List

Code	Description
E001	Smartphone
E002	Laptop
E003	Tablet
E004	Smartphone

- You can search for the value and description in the search bar.
- The advanced filter option is used to filter a value and description based on conditions which can be included or excluded. It can be applied in both value and description field.
  For Example:
  If you want to filter the description `Smartphone` from the list which has `Smartphone`, `Laptop`, and `Tablet`, then the condition can be applied in both the value and description field as the following.
  Include: Description is equal to `Smartphone`.
  Exclude: Value is equal to `E004`.
  So that the filtered result is `E001`, `Smartphone`.
- The value column can be sorted in both ascending and descending order.

> **i** Note
>
> The search and filter options are case sensitive.

Date Control

While authoring a rule in advanced mode, the auto-complete suggestion list of the Rule Builder UI control provides the date link where the value can be picked from the calendar. This date link is provided in the suggestion list, only if the attribute is of type date.

In the following example, the DOB of an employee is an attribute of type date. While authoring the rule, the date link is provided in the suggestion which opens a calendar from where the value can be selected and consumed in the rule.

```
    If
    DOB of an Employee is equal to '01/01/18'
    Then
    Discount
```

Step 1: Creating a Rule Control

In this step, we embed rule builder of type `TextRule` into an application view.

Coding

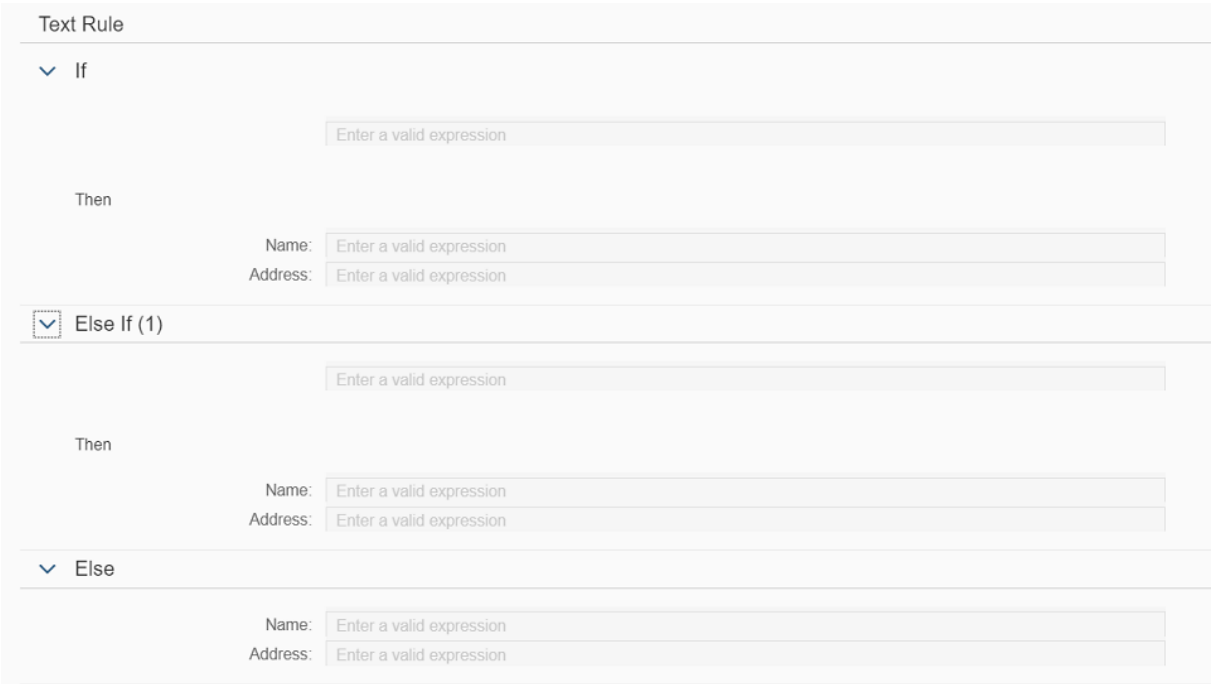
You can view and download all files at Rule Builder - Text Rule.

Page.view.xml

```
<mvc:View
        xmlns:mvc="sap.ui.core.mvc"
        displayBlock="true"
        xmlns="sap.m"
        controllerName="sap.rules.ui.sample.TextRule.Page"
        viewName="sap.rules.ui.sample.TextRule.Page.view"
        xmlns:rules="sap.rules.ui">
    <Button id="editButton" press="handleEditButton" text="Edit"/>
    <rules:RuleBuilder id="ruleBuilder" types="TextRule" editable="false"/>
</mvc:View>
```

Step 2: Associating the Expression Language

Preview



Coding

You can view and download all files at Rule Builder - Text Rule.

Page.controller.js

This code adds an expression language object to the view controller, and connects it to the `RuleBuilder`. For the expression language object, this code sets the model and then does all the necessary data binding internally (unlike other SAPUI5 controls where the developer defines the data binding). The data for expression language object is loaded via the vocabulary OData service.

Before you begin, customize the `Page.controller.js` as per your requirements.

- Set the expression language object:
  For rule expression language:

  ```
  oExpressionLanguage = new sap.rules.ui.services.ExpressionLanguage();
  oRuleBuilder.setExpressionLanguage(oExpressionLanguage);
  ```

  For DMN SFEEL:

  ```
  oAstExpressionLanguage = new sap.rules.ui.services.AstExpressionLanguage();
  oRuleBuilder.setAstExpressionLanguage(oAstExpressionLanguage);
  ```

- Ensure that you have set the data before setting the vocabulary model for the expression language as shown:

  ```
  oExpressionLanguage.setData(data);
  oExpressionLanguage.setModel(that.oVocabularyModel);
  ```

> **i Note**
>
> Text rule will not load if the batch mode is disabled. Set `setUseBatch` to `true` in the OData model used to enable batch mode.

The code also sets a binding context path on `RuleBuilder` to the specific rule you are currently working on.

```
 sap.ui.define([
    'jquery.sap.global',
    'sap/ui/core/mvc/Controller',
    'sap/ui/model/odata/v2/ODataModel',
    'sap/rules/ui/services/ExpressionLanguage',     //For DMN SFEEL, use 'sap/
rules/ui/services/AstExpressionLanguage'.
    'sap/ui/core/util/MockServer',
    'sap/m/MessageToast'
], function (jQuery, Controller, ODataModel, ExpressionLanguage, MockServer,
MessageToast) {   //For DMN SFEEL, use 'AstExpressionLanguage' instead of
'ExpressionLanguage'.

                }, "2");
            };
```

```
            aRequests.push({method: sMethod, path: sPath, response:
fnResponse6});

            sPath = /Projects\(Id='<project-id>',Version='<project-version>'\)\/
Rules\(Id='<rule-id>',Version='<rule-version>'\)\/TextRule\/TextRuleConditions\
(RuleId='<rule-id>',RuleVersion='<rule-version>',Id='1'\)\/
TextRuleResultExpressions\?\$skip=0&\$top=100/;
            var fnResponse7 = function (xhr) {
                 xhr.respondJSON(200, {
                    "Content-Type": "application/json;charset=utf-8"
                }, oRresponses.response_8);
            };
            aRequests.push({method: sMethod, path: sPath, response:
fnResponse7});

            sPath = /Projects\(Id='<project-id>',Version='<project-version>'\)\/
Rules\(Id='<rule-id>',Version='<rule-version>'\)\/TextRule\/TextRuleConditions\
(RuleId='<rule-id>',RuleVersion='<rule-version>',Id='2'\)\/
TextRuleResultExpressions\$count/;
            var fnResponse8 = function (xhr) {
                xhr.respond(200, {
                    "Content-Type": "text/plain;charset=utf-8"
                }, "2");
            };
            aRequests.push({method: sMethod, path: sPath, response:
fnResponse8});

            sPath = /Projects\(Id='<project-id>',Version='<project-version>'\)\/
Rules\(Id='<rule-id>',Version='<rule-version>'\)\/TextRule\/TextRuleConditions\
(RuleId='<rule-id>',RuleVersion='<rule-version>',Id='2'\)\/
TextRuleResultExpressions\?\$skip=0&\$top=100/;
            var fnResponse9 = function (xhr) {
                 xhr.respondJSON(200, {
                    "Content-Type": "application/json;charset=utf-8"
                }, oRresponses.response_9);
            };
            aRequests.push({method: sMethod, path: sPath, response:
fnResponse9});

            return aRequests;
        }
    });
});
```

The following are the code modifications that you can make to include additional functionalities:

- For reading specific vocabulary content like data objects, attributes, value help, rules or vocabulary rules, use the following code:

```
this.oVocabularyModel.read(sVocabularyPath, {
                urlParameters: {
                    "$expand": "DataObjects/Associations,DataObjects/
Attributes,ValueSources,Rules"
                },
```

- To set the vocabulary context shown in autosuggestion, use the following code:

```
oExpressionLanguage.setBindingContextPath("/Vocabularies(\'" + <vocabulary
context> + "\')");
```

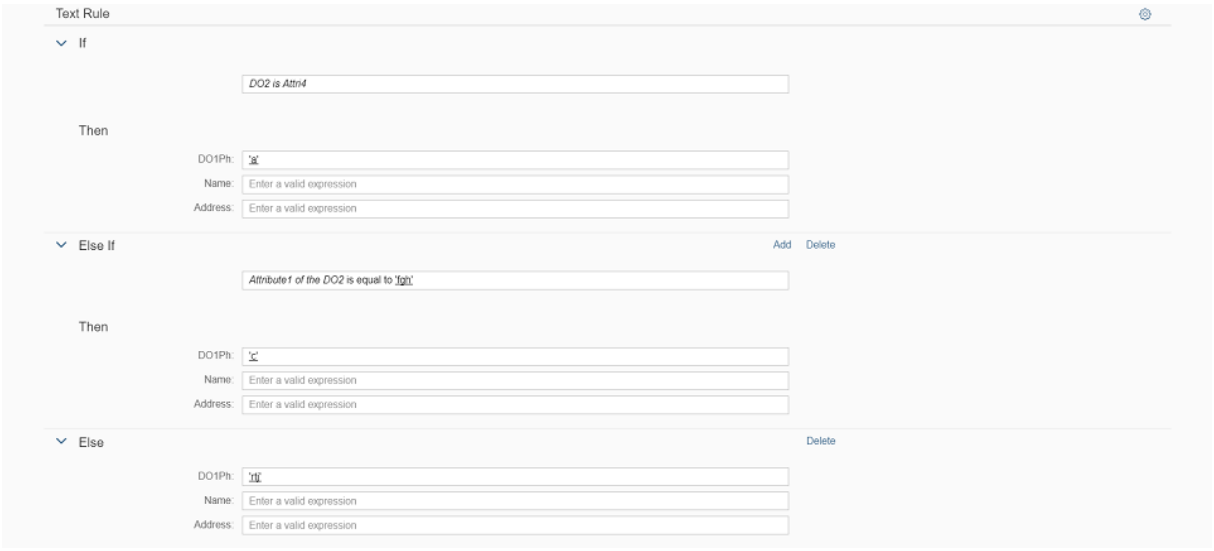
> **i Note**
>
> Vocabulary context is `ProjectId` by default and all the data objects of the given project are listed in autosuggestion. The possible contexts include `RuleserviceId`, `RuleId` and `ProjectId`.

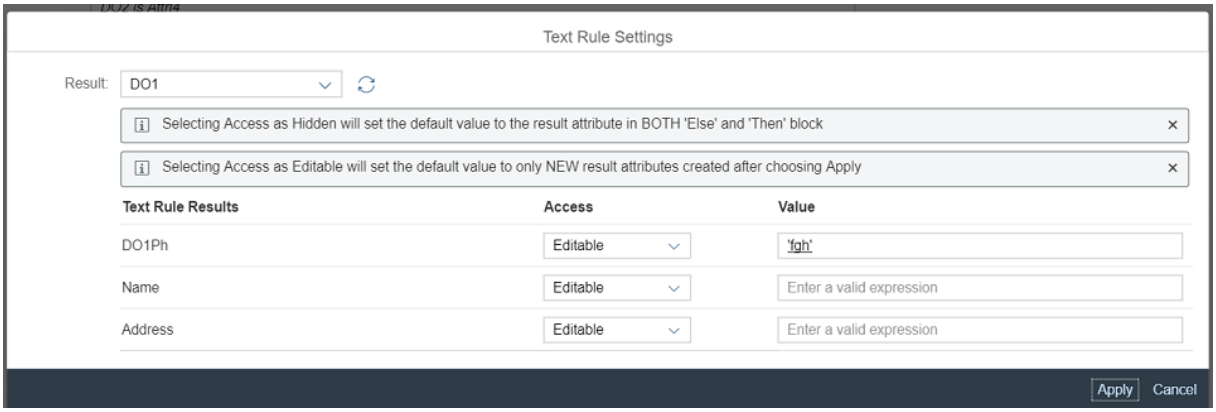
Step 3: Changing the Text Rule Configuration

Text rule has a set of configurations that influence different aspects of the its functionality and the actions that business users can perform. Part of the configuration of the text rule can be exposed to the end user via the text rule *Settings* dialog box.

Text rule has a condition part (`if, elseif`) and the result parts (`then, else`). In this type of rule authoring, the user can create a text rule which has different semantic fonts, colors for vocabulary (data), grammar (reserved words), inline error highlighting and provides the autocomplete feature to support user input for the rules (condition & results).

Preview





Coding

You can view and download all files at Rule Builder - Text Rule.

Page.view.xml

```
<mvc:View
        xmlns:mvc="sap.ui.core.mvc"
        displayBlock="true"
        xmlns="sap.m"
        controllerName="sap.rules.ui.sample.TextRule.Page"
        viewName="sap.rules.ui.sample.TextRule.Page.view"
        xmlns:rules="sap.rules.ui">
    <Button id="editButton" press="handleEditButton" text="Edit"/>
    <rules:RuleBuilder id="ruleBuilder" types="TextRule" editable="true">
        <rules:textRuleConfiguration>
        <rules:textRuleConfiguration enableSettings="true" enableElseIf=
"false"/>
        </rules:textRuleConfiguration>
    </rules:RuleBuilder>
</mvc:View>
```

The `enableSettings` option is `false` by default and can be set to `true` which enables the *Settings* icon, and opens the *Settings* dialog box. The `enableElse` and `enableElseIf` options are `true` by default and can be set to `false` which disables the `Else` and `ElseIf` parts in the condition.

Multiple `ElseIf` statements can also be configured in the condition.

Summary

We have now embedded a `TextRule` control in our application. We created a control that uses text input and bound it to data.

We also added a *Settings* button. You can click the *Settings* button to change settings for the text rule.

Smart Controls

In this tutorial you learn how to work with smart controls.

Smart controls are a specific category of SAPUI5 controls that have some special features in addition to the standard SAPUI5 features and thus make it easier to use the control in certain scenarios.

A primary example of such a feature is OData support: Typically, a smart control interprets OData metadata. In some cases, a smart control even persists an adapted version of the user interface that the user has defined for later usage.

In this tutorial, you see examples that should make the term “smart” even more tangible.

> → Tip
>
> You don't have to do all tutorial steps sequentially, you can also jump directly to any step you want. Just download the code from the previous step, copy it to your workspace and make sure that the application runs by calling the `webapp/index.html` file.

You can view and download the files for all steps in the *Samples* in the Demo Kit at Smart Controls. Depending on your development environment you might have to adjust resource paths and configuration entries.

For more information check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]

Prerequisites

Preparation steps for the *Smart Controls* tutorial

You have already gone through the following tutorials:

- Walkthrough [page 69]
- Data Binding [page 219]

In addition, you need some background knowledge about OData and annotations that you can find here: http://www.sap.com/protocols/SAPData.

> **i Note**
>
> The smart controls require a default OData model, and named models are not supported.

You need a web server to host the files that are created in the tutorial steps, and you need the relevant SAPUI5 libraries, of course.

Please note that for each step there is a separate folder with its own copy of the files used.

File Structure

For each step we will create the following files:

- webapp (folder)
  - test (folder)
    - service (folder)
      - `metadata.xml`
      - `<Entity>.json` (could be more than one file)
      - server.js
  - `Component.js`
  - `index.html`
  - `manifest.json`
  - `<ControlName>.controller.js`
  - `<ControlName>.view.xml`
- `Component.js`

In some steps, additional files are needed. They will be explained in those steps. Since many of these files are almost identical from step to step, we show their content here but only briefly point to interesting points in these files if necessary. Please refer to the *Walkthrough* tutorial for further details on the general setup and the content of the outer `Component.js` file (the top-level file on the same level as the webapp folder) in which we define that the `index.html` will be shown in an iFrame.

index.html

```
<!DOCTYPE html>
<html>
<head>
<meta http-equiv="X-UA-Compatible" content="IE=edge">
<meta charset="utf-8">
<title>SmartControls</title>
<script id="sap-ui-bootstrap"
    src="../../../../../../../../../resources/sap-ui-core.js"
    data-sap-ui-theme="sap_belize"
    data-sap-ui-libs="sap.m, sap.ui.comp"
    data-sap-ui-bindingSyntax="complex"
    data-sap-ui-compatVersion="edge"
    data-sap-ui-preload="async"
    data-sap-ui-resourceroots='{
        "sap.ui.demo.smartControls": "./"
    }'>
</script>
<script>
    sap.ui.getCore().attachInit(function() {
        sap.ui.require([
            "sap/ui/demo/smartControls/test/service/server"
        ], function(server) {
            server.init();
            new sap.ui.core.ComponentContainer({
                name: "sap.ui.demo.smartControls",
                height: "100%"
            }).placeAt("content");
        });
    });
</script>
</head>
<body class="sapUiBody" id="content">
</body>
</html>
```

In this index file, you will recognize that we reference the library `sap.ui.comp` since this is the **main library** for the smart controls. This `index.html` file references the `Component.js` (through the name: "sap.ui.demo.smartControls") which always looks like this:

Component.js

```
sap.ui.define([
    "sap/ui/core/UIComponent"
], function(UIComponent) {
    "use strict";
    return UIComponent.extend("sap.ui.demo.smartControls.Component", {
        metadata: {
```

```
            manifest: "json"
        }
    });
});
```

In the `Component.js` file we use the `manifest.json` file.

manifest.json

```
{
  "_version": "1.8.0",
  "sap.app": {
    "id": "sap.ui.demo.smartControls",
    "type": "application",
    "title": "SAPUI5 Smart Controls",
    "description": "A simple app that explains the most important concepts of
smart controls in SAPUI5",
    "applicationVersion": {
        "version": "1.0.0"
    },
    "dataSources": {
      "mainService": {
        "uri": "/here/goes/your/serviceUrl/",
        "type": "OData",
        "settings": {
          "odataVersion": "2.0"
          "localUri": "localService/metadata.xml"
        }
      }
    }
  },
  "sap.ui": {
    "technology": "UI5"
  },
  "sap.ui5": {
    "rootView": {
        "viewName": "sap.ui.demo.smartControls.SmartField",
        "type": "XML"
        "async": true
    },
    "dependencies": {
      "minUI5Version": "1.30",
      "libs": {
        "sap.m": {},
        "sap.ui.comp": {}
      }
    },
    "models": {
       "": {
        "dataSource": "mainService",
        "settings": {
            "defaultBindingMode": "TwoWay"
        }
      }
    }
  }
}
```

In the `manifest.json` file we define the `rootView` and also the model of the application. Please note that the `TwoWay` binding mode ensures that an input validation is done automatically based on the metadata.

The last file that we wish to list here is the `server.js`:

server.js

```
sap.ui.define([
    "sap/ui/core/util/MockServer"
], function (MockServer) {
    "use strict";
    return {
        init: function () {
            // create
            var oMockServer = new MockServer({
                rootUri: "/here/goes/your/serviceUrl/"
            });
            // configure
            MockServer.config({
                autoRespond: true,
                autoRespondAfter: 1000
            });
            // simulate
            var sPath =
jQuery.sap.getModulePath("sap.ui.demo.smartControls.test.service");
            oMockServer.simulate(sPath + "/metadata.xml", sPath);
            // start
            oMockServer.start();
        }
    };
});
```

In this file we define the `MockServer` handling the server requests.

> **i** Note
>
> You might notice the rather flat setup of the files that is different from the setup propagated in the *Walkthrough* tutorial where the `Model-View-Controller` paradigm is reflected in the folder structure. We have chosen the flat setup for this tutorial since our examples all have exactly **one** single file for the view and **one** single file for the controller. Additional folders would add a complexity that we would like to avoid.

Step 1: Smart Field

One important building block of smart controls is the `SmartField` control that, depending on the OData metadata defined, allows you to render other controls and, for example, define fields with certain attributes based on the metadata.

So we start our journey into the world of smart controls by looking at the `SmartField` control and, in particular, an example in which a price together with its currency is displayed. Later we will see more complex examples.

Preview

Figure 164: Smart Field

Coding

You can view and download all files in the *Samples* in the Demo Kit at Smart Controls - Step 1 - Smart Field.

SmartField.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.smartControls.SmartField"
    xmlns="sap.m"
    xmlns:smartForm="sap.ui.comp.smartform"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:sap.ui.layout="sap.ui.layout"
    xmlns:smartField="sap.ui.comp.smartfield">
    <smartForm:SmartForm editable="true">
        <smartForm:layout>
            <smartForm:ColumnLayout
                emptyCellsLarge="4"
                labelCellsLarge="4"
                columnsM="1"
                columnsL="1"
                columnsXL="1"/>
        </smartForm:layout>
        <smartForm:Group>
            <smartForm:GroupElement>
                <smartField:SmartField value="{Price}" id="idPrice"/>
            </smartForm:GroupElement>
        </smartForm:Group>
    </smartForm:SmartForm>
</mvc:View>
```

This view basically specifies a form with an appropriate layout, the content of which consists of a `SmartLabel` control along with a `SmartField` control . The connection between `SmartLabel` and `SmartField` is essential since metadata for `SmartLabel` is controlled via the binding of `SmartField`. `SmartField` and `SmartLabel` are connected by `id` and `labelFor`, respectively, in this case `idPrice`.

SmartField.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function(Controller) {
    "use strict";
    return Controller.extend("sap.ui.demo.smartControls.SmartField", {
        onInit: function() {
            this.getView().bindElement("/Products('4711')");
```

```
        }
    });
});
```

In the `SmartField.controller.js` file you will see that we bind the view to `"/Products('4711')"`.

metadata.xml

```
<?xml version="1.0" encoding="utf-8"?>
<edmx:Edmx Version="1.0"
           xmlns:edmx="http://schemas.microsoft.com/ado/2007/06/edmx"
           xmlns:m="http://schemas.microsoft.com/ado/2007/08/dataservices/
metadata"
           xmlns:sap="http://www.sap.com/Protocols/SAPData">
    <edmx:DataServices m:DataServiceVersion="2.0">
        <Schema Namespace="com.sap.wt01"
                sap:schema-version="1" xmlns="http://schemas.microsoft.com/ado/
2008/09/edm">
            <EntityType Name="Product">
                <Key>
                    <PropertyRef Name="ProductId"/>
                </Key>
                <Property Name="ProductId" Type="Edm.String"/>
                <Property Name="Price" Type="Edm.String"
                          sap:unit="CurrencyCode" MaxLength="3" sap:label="Price"
                          sap:updatable="true"/>
                <Property Name="CurrencyCode" Type="Edm.String"
                          MaxLength="3" sap:label="Currency"
sap:semantics="currency-code"
                          sap:updatable="true"/>
            </EntityType>
            <EntityContainer m:IsDefaultEntityContainer="true"
                             sap:supported-formats="atom json">
                <EntitySet Name="Products" EntityType="com.sap.wt01.Product"
                           sap:updatable="true"/>
            </EntityContainer>
        </Schema>
    </edmx:DataServices>
</edmx:Edmx>
```

The metadata document corresponds to the `$metadata` document of your OData service. You will find the `Price` and the `CurrencyCode` metadata here, and, in particular, you will see that the `Price` property defines `CurrencyCode` as its unit. The relationship is automatically picked up by `SmartField`, and it decides on the particular rendering of the price along with with its currency based on additional metadata, such as `Type` and `MaxLength`. With `sap:updatable="true"` we define that the field is editable; `sap:updatable="false"` would indicate that the field is read-only. All Boolean-like properties default to true if not specified otherwise. To make this clearer, however, we sometimes still include them in the `metadata.xml` document, like `sap:updatable="true"` in this case. Later, we will see other examples of how the `SmartField` control shows a "smart" behavior as to which controls are rendered on the UI.

Products.json

```
[{
```

```
    "ProductId": "4711",
    "Price": 856.49,
    "CurrencyCode": "EUR"
}]
```

Finally, we include the `Products.json` file (as referred to in the `metadata.xml` as `EntitySet`) in our example, which contains the data shown on the UI.

Smart Field [page 2410]

Step 2: Smart Field with Value Help

You can use the `SmartField` control in combination with the `ValueHelpDialog` control that allow you to carry out a complex search in order to identify the value you are looking for.

We would like to stress the importance of this feature with a dedicated example, even though you might argue that this is just another feature of the `SmartField` control. In the following example, we see a value help for a currency code. By providing a value help, the user can find the correct currency by firing a query with complex input parameters. Surely, you can imagine that there are more complex examples in which specifying the correct value is almost impossible without performing a query. For example, when providing a customer ID, you would want to find this based on the last name of the customer.

We would like to emphasize here that the response to the query input (whether it is the response to the query input for the main table, as we will see later, or whether it is related to the value help, as we will see here) heavily depends on the server handling the request. In our case, the `MockServer` is not a full-fledged implementation that handles all OData requests as the user might expect. Therefore, please bear in mind that the examples are intended for a tutorial and not a real application.

Preview

Figure 165: Smart Field with Value Help

There is a small icon right next to the currency code. After pressing this icon you see a dialog (the `ValueHelpDialog` control) on which a query can be executed.

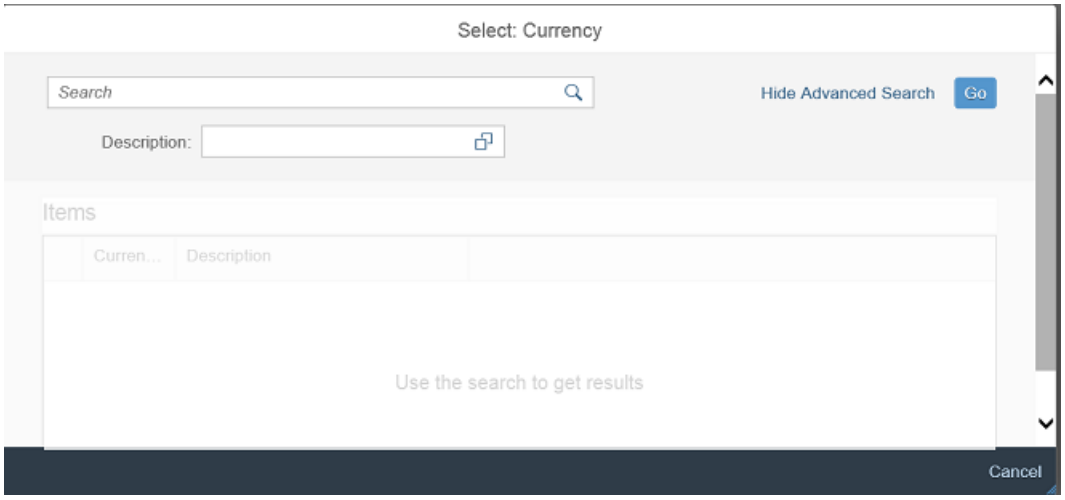

Figure 166: Value Help

Coding

You can view and download all files in the *Samples* in the Demo Kit at Smart Controls - Step 2 - Smart Field with Value Help.

SmartFieldWithValueHelp.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.smartControls.SmartFieldWithValueHelp"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:smartForm="sap.ui.comp.smartform"
    xmlns:sap.ui.layout="sap.ui.layout"
    xmlns:smartField="sap.ui.comp.smartfield">
    <smartForm:SmartForm editable="true">
        <smartForm:layout>
            <smartForm:ColumnLayout
                emptyCellsLarge="4"
                labelCellsLarge="4"
                columnsM="1"
                columnsL="1"
                columnsXL="1"/>
        </smartForm:layout>
        <smartForm:Group>
            <smartForm:GroupElement>
                <smartField:SmartField value="{Price}" id="idPrice"/>
            </smartForm:GroupElement>
        </smartForm:Group>
    </smartForm:SmartForm>
</mvc:View>
```

For the view definition, we see that there is no difference to the previous example. This is an important fact since this exemplifies the underlying idea of what we mean by “smart”: Depending on the metadata, the control automatically adjusts its behavior.

SmartField.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function(Controller) {
    "use strict";
    return
Controller.extend("sap.ui.demo.smartControls.SmartFieldWithValueHelp", {
        onInit: function() {
            this.getView().bindElement("/Products('4711')");
        }
    });
});
```

Again, this file is in essence identical with the controller in step 1.

metadata.xml

```
<?xml version="1.0" encoding="utf-8"?>
<edmx:Edmx Version="1.0"
    xmlns:edmx="http://schemas.microsoft.com/ado/2007/06/edmx"
    xmlns:m="http://schemas.microsoft.com/ado/2007/08/dataservices/metadata"
    xmlns:sap="http://www.sap.com/Protocols/SAPData">
    <edmx:DataServices m:DataServiceVersion="2.0">
        <Schema Namespace="com.sap.wt02"
            sap:schema-version="1" xmlns="http://schemas.microsoft.com/ado/
2008/09/edm">
            <EntityType Name="Product">
                <Key>
                    <PropertyRef Name="ProductId" />
                </Key>
                <Property Name="ProductId" Type="Edm.String" />
                <Property Name="Price" Type="Edm.String"
                    sap:unit="CurrencyCode" MaxLength="3" sap:label="Price"
                    sap:updatable="true" />
                <Property Name="CurrencyCode" Type="Edm.String"
                    MaxLength="3" sap:label="Currency" sap:semantics="currency-
code"
                    sap:updatable="true" />
            </EntityType>
            <EntityType Name="Currency">
                <Key>
                    <PropertyRef Name="CURR" />
                </Key>
                <Property Name="CURR" Type="Edm.String" MaxLength="4"
                    sap:display-format="UpperCase" sap:text="DESCR"
sap:label="Currency Code"
                    sap:filterable="false" />
                <Property Name="DESCR" Type="Edm.String" MaxLength="25"
                    sap:label="Description" />
            </EntityType>
            <EntityContainer m:IsDefaultEntityContainer="true"
                sap:supported-formats="atom json">
                <EntitySet Name="Products" EntityType="com.sap.wt02.Product" />
                <EntitySet Name="Currency" EntityType="com.sap.wt02.Currency" />
            </EntityContainer>
            <Annotations Target="com.sap.wt02.Product/CurrencyCode"
                xmlns="http://docs.oasis-open.org/odata/ns/edm">
                <Annotation Term="com.sap.vocabularies.Common.v1.ValueList">
                    <Record>
```

```
                        <PropertyValue Property="Label" String="Currency" />
                        <PropertyValue Property="CollectionPath"
String="Currency" />
                        <PropertyValue Property="SearchSupported" Bool="true" />
                        <PropertyValue Property="Parameters">
                            <Collection>
                                <Record
Type="com.sap.vocabularies.Common.v1.ValueListParameterOut">
                                    <PropertyValue Property="LocalDataProperty"
                                        PropertyPath="CurrencyCode" />
                                    <PropertyValue Property="ValueListProperty"
                                        String="CURR" />
                                </Record>
                                <Record

Type="com.sap.vocabularies.Common.v1.ValueListParameterDisplayOnly">
                                    <PropertyValue Property="ValueListProperty"
                                        String="DESCR" />
                                </Record>
                            </Collection>
                        </PropertyValue>
                    </Record>
                </Annotation>
            </Annotations>
        </Schema>
    </edmx:DataServices>
</edmx:Edmx>
```

As stated above, the metadata file is the place in which the difference to step 1 can be found - we have highlighted the changes. We will dig deeper into this file now.

First we inspect the added entity type:

```
<EntityType Name="Currency" sap:content-version="1">
<Key>
        <PropertyRef Name="CURR" />
    </Key>
    <Property Name="CURR" Type="Edm.String" MaxLength="4"
sap:display-format="UpperCase" sap:text="DESCR"
sap:label="Currency Code" sap:filterable="false"/>
    <Property Name="DESCR" Type="Edm.String" MaxLength="25"
sap:label="Description"/>
</EntityType>
```

We notice that we have set `sap:filterable="false"` for the `CURR` property. We do this, since we would otherwise also have a currency code search field in the dialog that we wish to avoid (default of `sap:filterable` is true).

Now let us look at the `ValueList` annotation:

```
<Annotations Target="com.sap.wt02.Product/CurrencyCode"
                xmlns="http://docs.oasis-open.org/odata/ns/edm">
<Annotation Term="com.sap.vocabularies.Common.v1.ValueList">
    <Record>
        <PropertyValue Property="Label" String="Currency"/>
        <PropertyValue Property="CollectionPath" String="Currency"/>
        <PropertyValue Property="SearchSupported" Bool="true"/>
        <PropertyValue Property="Parameters">
            <Collection>
<Record Type="com.sap.vocabularies.Common.v1.ValueListParameterOut">
                    <PropertyValue Property="LocalDataProperty"
PropertyPath="CurrencyCode" />
                    <PropertyValue Property="ValueListProperty" String="CURR" />
                </Record>
                <Record
```

```
Type="com.sap.vocabularies.Common.v1.ValueListParameterDisplayOnly">
                    <PropertyValue Property="ValueListProperty" String="DESCR" />
                </Record>
            </Collection>
        </PropertyValue>
    </Record>
</Annotation>
</Annotations>
```

With the metadata `Target="com.sap.wt02.Product/CurrencyCode"`, we define that the `CurrencyCode` of the `EntityType Product` will have a `ValueList` (or `ValueHelp`) associated to it. We set the property `SearchSupported` to true in order to get a general search field. This is the field in the dialog that has the *Search* shadow text.

```
<Record Type="com.sap.vocabularies.Common.v1.ValueListParameterOut">
                    <PropertyValue Property="LocalDataProperty"
PropertyPath="CurrencyCode" />
                    <PropertyValue Property="ValueListProperty" String="CURR" />
                </Record>
```

This specification defines that the value help will export the value of the `CURR` field to the `CurrencyCode` field using `ValueListParameterOut`. This export happens, for example, by selecting an entry in the list of currency values.

Lastly, as for the `ValueList` annotation, we specify with the following specification that the `DESCR` field is shown in the table (but only for display purposes in the sense that no interaction with the content of this field is possible):

```
<Record Type="com.sap.vocabularies.Common.v1.ValueListParameterDisplayOnly">
                    <PropertyValue Property="ValueListProperty" String="DESCR" />
</Record>
```

Products.json

```
[{
    "ProductId": "4711",
    "Price": 856.49,
    "CurrencyCode": "EUR"
}]
```

Since the product we show initially is the same as in step 1, there is no change to the `Products.json` file.

Currency.json

```
[{
    "CURR": "EUR",
    "DESCR": "European Euro"
},
{
    "CURR": "USD",
    "DESCR": "United States Dollar"
},
```

```
{
    "CURR": "GBP",
    "DESCR": "British Pound"
},
{
    "CURR": "DKK",
    "DESCR": "Danish Krone"
},
{
    "CURR": "INR",
    "DESCR": "Indian Rupee"
},
{
    "CURR": "NOK",
    "DESCR": "Norwegian Krone"
},
{
    "CURR": "SEK",
    "DESCR": "Swedish Krona"
},
{
    "CURR": "CHF",
    "DESCR": "Swiss Franc"
}]
```

In the newly added `Currency.json` file, we include the values needed for the currency entities.

Related Information

Smart Field [page 2410]

Step 3: Smart Field with Smart Link

We now show yet another but quite different feature of the `SmartField` control, `SmartField` used in combination with `SmartLink`, which allow you to embed a dialog with related cross-application links.

We will learn that a `SmartField` control in an XML view bound to an OData model with a `SemanticObject` annotation renders a special link that shows a dialog containing different cross-application links. These cross-application links are neither configured within the XML view nor directly specified in the OData metadata. The information about these links is extracted automatically when the view is running in the SAP Fiori launchpad or, more generally, the unified shell.

Preview

Figure 167: Smart Field with Smart Link

When you choose the link, a dialog opens:

Figure 168: Dialog with Navigation Targets

When you choose *Define Links*, a dialog opens where you can select the cross-application links you want to see.

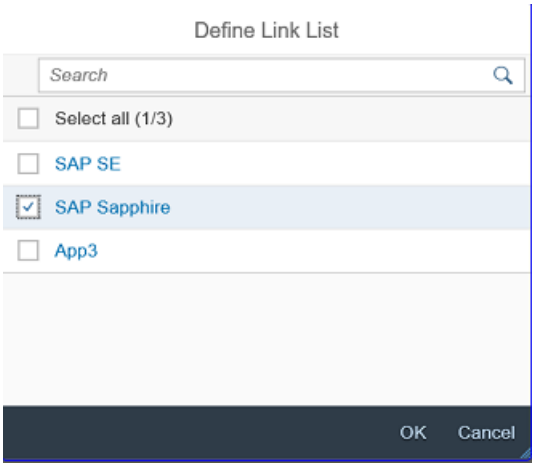

Figure 169: Link List

After your selection, the dialog looks like this:

Figure 170: Changed Links

You can choose *More* to go back to the link list.

Coding

You can view and download all files in the *Samples* in the Demo Kit at Smart Controls - Step 3 - Smart Field with Smart Link.

To have a working example, we include the `UShellCrossApplicationNavigationMock.js` class. This class basically mocks the required services, which would normally be available in the SAP Fiori launchpad. These services provide the cross-application navigation targets along with the URL parsing, thus making it possible to determine which link qualifies as a “fact sheet” target. As these services will be provided for in a real-world

scenario, we will not analyze the mock class in more detail and also not provide a code listing of the class. The class file can be found in the *Samples*.

SmartLink.view.xml

```
<mvc:View
    controllerName="sap.ui.demo.smartControls.SmartLink"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:smartForm="sap.ui.comp.smartform"
    xmlns:sap.ui.layout="sap.ui.layout"
    xmlns:smartField="sap.ui.comp.smartfield">
    <smartForm:SmartForm editable="true">
        <smartForm:layout>
            <smartForm:ColumnLayout
                emptyCellsLarge="4"
                labelCellsLarge="4"
                columnsM="1"
                columnsL="1"
                columnsXL="1"/>
        </smartForm:layout>
        <smartForm:Group>
            <smartForm:GroupElement>
                <smartField:SmartField value="{Name}" id="idName"
editable="false"/>
            </smartForm:GroupElement>
        </smartForm:Group>
    </smartForm:SmartForm>
</mvc:View>
```

We recognize our setup of the previous two examples in the `view.xml`. We are referring to a different field, but apart from this, there is no substantial change. The `SmartField` control is rendered as a link in the display mode. We set `editable` to `false` to achieve the same effect in this example.

SmartLink.controller.js

```
sap.ui.define([
    'sap/ui/core/mvc/Controller', 'sap/ui/demo/smartControls/test/service/
UShellCrossApplicationNavigationMock'
], function(Controller, UShellCrossApplicationNavigationMock) {
    "use strict";
    return Controller.extend("sap.ui.demo.smartControls.SmartLink", {
        onInit: function() {
            this.getView().bindElement("/Products('4711')");
            UShellCrossApplicationNavigationMock.mockUShellServices({
                tutorial_03_Name: {
                    links: [
                        {
                            action: "sap_se",
                            intent: "http://www.sap.com",
                            text: "SAP SE"
                        }, {
                            action: "sap_sapphire",
                            intent: "http://www.sap.com/sapphire",
                            text: "SAP Sapphire"
                        }, {
```

```
                            action: "app3",
                            intent: "http://www.sap.com/hana",
                            text: "App3"
                        }
                    ]
                }
            });
        },
        onExit: function() {
            UShellCrossApplicationNavigationMock.unMockUShellServices();
        }
    });
});
```

We notice the instantiation of the mock class `UShellCrossApplicationNavigationMock` mentioned above and also the subsequent destroy.

metadata.xml

```
<?xml version="1.0" encoding="utf-8"?>
<edmx:Edmx Version="1.0"
    xmlns:edmx="http://schemas.microsoft.com/ado/2007/06/edmx"
    xmlns:m="http://schemas.microsoft.com/ado/2007/08/dataservices/metadata"
    xmlns:sap="http://www.sap.com/Protocols/SAPData">
    <edmx:DataServices m:DataServiceVersion="2.0">
        <Schema Namespace="com.sap.wt03"
            sap:schema-version="1" xmlns="http://schemas.microsoft.com/ado/
2008/09/edm">
            <EntityType Name="Product">
                <Key>
                    <PropertyRef Name="ProductId" />
                </Key>
                <Property Name="ProductId" Type="Edm.String" />
                <Property Name="Name" Type="Edm.String" sap:label="My Favorite
Product" />
            </EntityType>
            <EntityContainer m:IsDefaultEntityContainer="true"
                sap:supported-formats="json">
                <EntitySet Name="Products" EntityType="com.sap.wt03.Product" />
            </EntityContainer>
            <Annotations Target="com.sap.wt03.Product/Name"
                xmlns="http://docs.oasis-open.org/odata/ns/edm">
                <Annotation Term="com.sap.vocabularies.Common.v1.SemanticObject"
                    String="tutorial_03_Name" />
            </Annotations>
        </Schema>
    </edmx:DataServices>
</edmx:Edmx>
```

As you would expect, one piece of configuration is found in the metadata, namely the `SemanticObject` annotation. With this annotation we ensure that the `SmartField` embeds a special link control, the `SmartLink` control. Let's assume we are running in a unified shell that provides the services `CrossApplicationNavigation` and `URLParsing` (that we are mocking in our `UShellCrossApplicationNavigationMock` class). In this case, when the link is pressed, the `SmartLink` control triggers these service calls, analyzes the result, and renders the cross-application links accordingly. Since these services deliver configuration content of the unified shell, `SmartLink` is controlled by more than just OData metadata.

Products.json

```
[{
    "ProductId": "4711",
    "Name": "SAP HANA"
}]
```

We list the content of this for reasons of completeness. We note that this JSON file only contains the data shown for the link, nothing related to the dialog.

Step 4: Smart Form

The `SmartForm` control is used to obtain a form-like layout for several controls.

`SmartForm` internally uses the `sap.ui.layout.form.Form` control. When using the `SmartForm` control in combination with the `SmartField` controls, the `view.xml` file remains very compact since required information about labels and headers is automatically extracted from the OData metadata. In addition, you can specify in `SmartForm` that it is toggle-editable in which case you get the option to switch between read-only and edit mode. In this case, the powerful features of the `SmartField` control really come to life, such as the value help and the smart links.

Preview

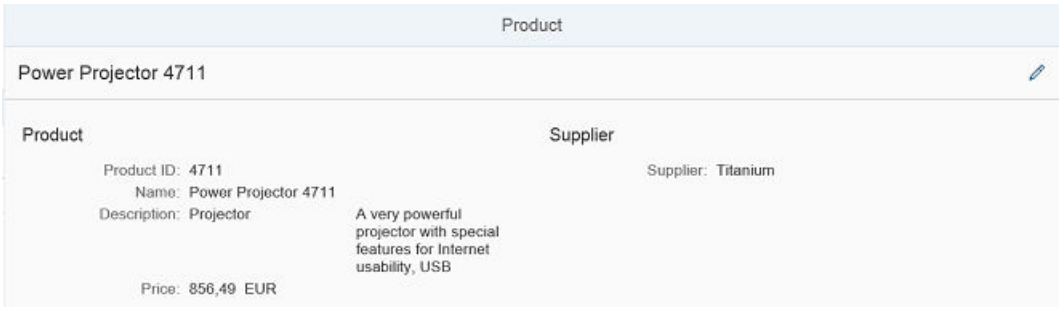

Figure 171: Smart Form with Several Smart Fields (Initial Read-Only Mode)

When you press the pencil icon, the dialog for `SmartForm` becomes editable:

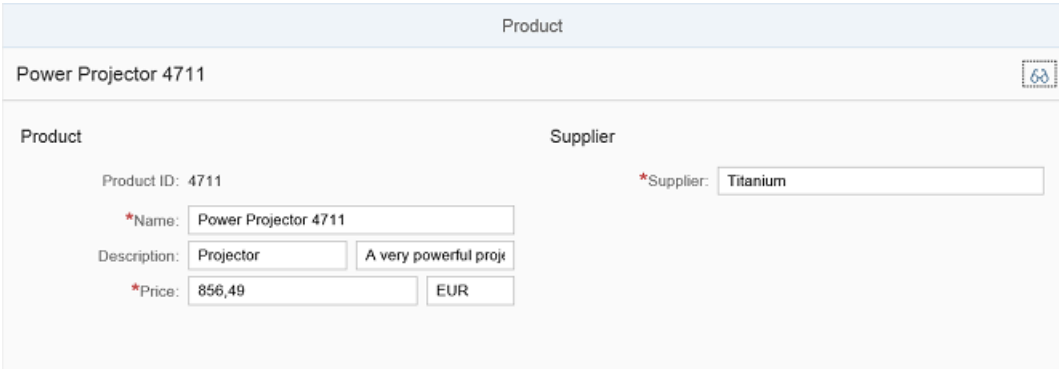

Figure 172: Smart Form with Several Smart Fields (Edit Mode)

When pressing the eyeglasses icon, you return to the display view of `SmartForm`.

Coding

You can view and download all files in the *Samples* in the Demo Kit at Smart Controls - Step 4 - Smart Form.

SmartForm.view.xml

```
<mvc:View
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    controllerName="sap.ui.demo.smartControls.SmartForm"
    xmlns:smartForm="sap.ui.comp.smartform"
    xmlns:smartField="sap.ui.comp.smartfield">
    <smartForm:SmartForm
        id="smartForm"
        editTogglable="true"
        title="{Name}"
        flexEnabled="false">
        <smartForm:Group label="Product">
            <smartForm:GroupElement>
                <smartField:SmartField value="{ProductId}" />
            </smartForm:GroupElement>
            <smartForm:GroupElement>
                <smartField:SmartField value="{Name}" />
            </smartForm:GroupElement>
            <smartForm:GroupElement elementForLabel="1">
                <smartField:SmartField value="{CategoryName}" />
                <smartField:SmartField value="{Description}" />
            </smartForm:GroupElement>
            <smartForm:GroupElement>
                <smartField:SmartField value="{Price}" />
            </smartForm:GroupElement>
        </smartForm:Group>
        <smartForm:Group label="Supplier">
            <smartForm:GroupElement>
                <smartField:SmartField value="{SupplierName}" />
            </smartForm:GroupElement>
        </smartForm:Group>
```

```
    </smartForm:SmartForm>
</mvc:View>
```

We see that we have several new elements here. `Group` instructs the `SmartForm` to add a container for the child elements. In this case, we have two top-level containers of elements, one for `Product` and one for `Supplier`. With the `GroupElement` added as a wrapper control for `SmartFields`, we instruct the `SmartForm` to inspect the OData metadata and automatically add the labels found there. Within such `GroupElements`, we can even define a compound field having exactly one label in front. We do this in the example above in order to combine `CategoryName` with `Description`. With `elementForLabel="1"` we define that the label `Description` for `SmartField` (found in the OData metadata) is used for both fields. `flexEnabled="false"` is set to deactivate SAPUI5 flexibility, since these features are not part of this tutorial.

SmartForm.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function(Controller) {
    "use strict";
    return Controller.extend("sap.ui.demo.smartControls.SmartForm", {
        onInit: function() {
            this.getView().byId("smartFormPage").bindElement("/
Products('4711')");
        }
    });
});
```

The controller follows the pattern that we already know.

metadata.xml

```
<?xml version="1.0" encoding="utf-8"?>
<edmx:Edmx Version="1.0"
    xmlns:edmx="http://schemas.microsoft.com/ado/2007/06/edmx"
    xmlns:m="http://schemas.microsoft.com/ado/2007/08/dataservices/metadata"
    xmlns:sap="http://www.sap.com/Protocols/SAPData">
    <edmx:DataServices m:DataServiceVersion="2.0">
        <Schema Namespace="com.sap.wt04"
            sap:schema-version="1" xmlns="http://schemas.microsoft.com/ado/
2008/09/edm">
            <EntityType Name="Product">
                <Key>
                    <PropertyRef Name="ProductId" />
                </Key>
                <Property Name="ProductId" Type="Edm.String" Nullable="false"
                    sap:updatable="false" MaxLength="20" sap:label="Product
ID" />
                <Property Name="Name" Type="Edm.String" Nullable="false"
                    MaxLength="30" sap:label="Name" />
                <Property Name="CategoryName" Type="Edm.String"
sap:label="Category Description"
                    sap:updatable="true" />
                <Property Name="Description" Type="Edm.String" MaxLength="256"
                    sap:label="Description" sap:updatable="true" />
                <Property Name="Price" Type="Edm.String" Nullable="false"
```

```
                    sap:unit="CurrencyCode" MaxLength="3" sap:label="Price"
                    sap:updatable="true" />
                <Property Name="CurrencyCode" Type="Edm.String" Nullable="true"
                    MaxLength="3" sap:label="Currency" sap:semantics="currency-
code"
                    sap:updatable="true" />
                <Property Name="SupplierName" Type="Edm.String" Nullable="false"
                    sap:label="Supplier" sap:updatable="true" />
            </EntityType>
            <EntityContainer m:IsDefaultEntityContainer="true"
                sap:supported-formats="atom json">
                <EntitySet Name="Products" EntityType="com.sap.wt04.Product" />
            </EntityContainer>
        </Schema>
    </edmx:DataServices>
</edmx:Edmx>
```

With `Nullable="false"` we define that the field is mandatory and therefore cannot be null. The label for the mandatory field is then marked with * on the UI. Other than that, there are no substantial differences in the metadata file. We only notice that the `sap:label` attributes defined here appear in the final form as explained before.

Products.json

```
[{
    "ProductId": "4711",
    "Name": "Power Projector 4711",
    "CategoryName": "Projector",
    "SupplierName": "Titanium",
    "Description": "A very powerful projector with special features for Internet
usability, USB",
    "Price": 856.49,
    "CurrencyCode": "EUR"
}]
```

We see that a few attributes have been changed and added to the JSON file, reflecting the fact that, in this step, more data is shown.

Smart Form [page 2420]

Step 5: Smart Filter Bar and Smart Table

In this step, we will look at the `SmartTable` control along with the `SmartFilterBar` control that allow you to filter table entries.

In the context of `SmartTable`, there are several central features that can be activated:

- Table personalization

- View management with the `VariantManagement` control
- Export to Microsoft Excel

In this step, we will look at `SmartTable` without table personalization or view management. These will be treated as separate steps. In addition, we will first focus on `SmartTable` with `sap.m.Table` as the underlying table type. This table type is best suited for a responsive behavior and is even designed to be used on a smart phone or a tablet.

Preview

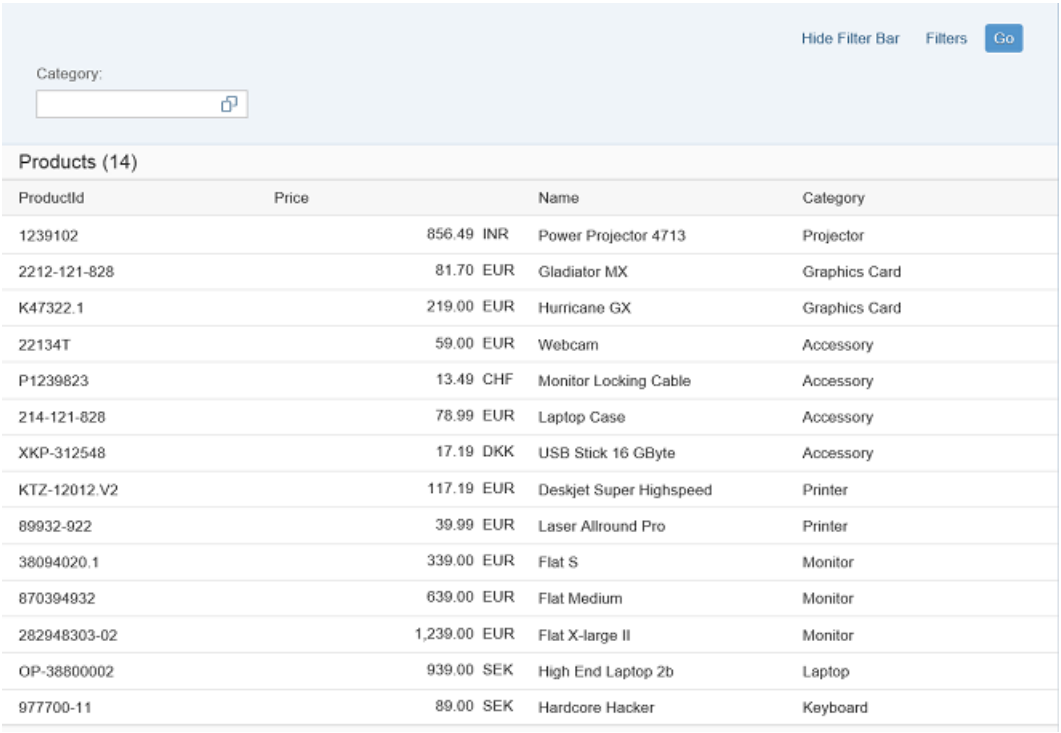

Figure 173: Initial Look of the Smart Filter Bar and the Smart Table, and the Results of Firing the Query

When choosing the *Filters* link, you see a popup:

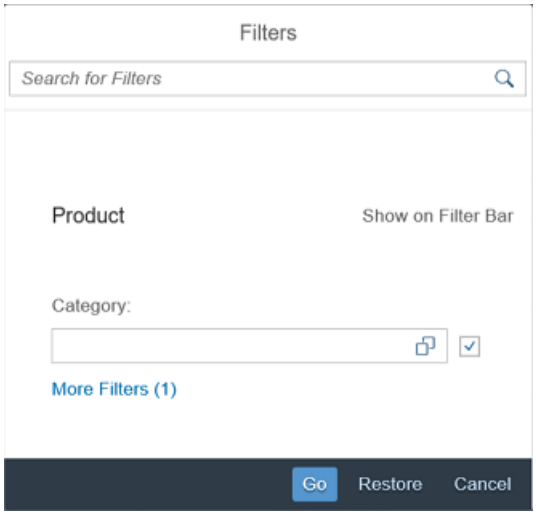

Figure 174: Dialog for Changing the Filter Values and Defining the Fields Displayed in the Filter Bar

Here you can press *More Filters*, which takes you to another dialog box.

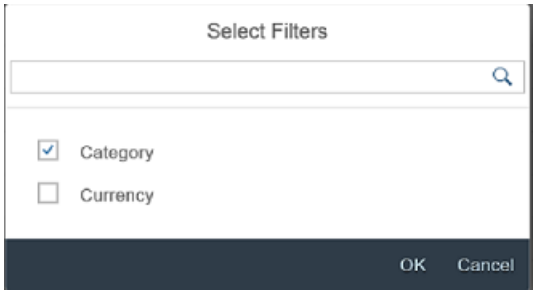

Figure 175: Dialog for Defining Additional Fields

When selecting the currency as an additional filter field for the table query and pressing *OK*, you can now select *Currency* as an additional field in the filter bar of the first dialog:

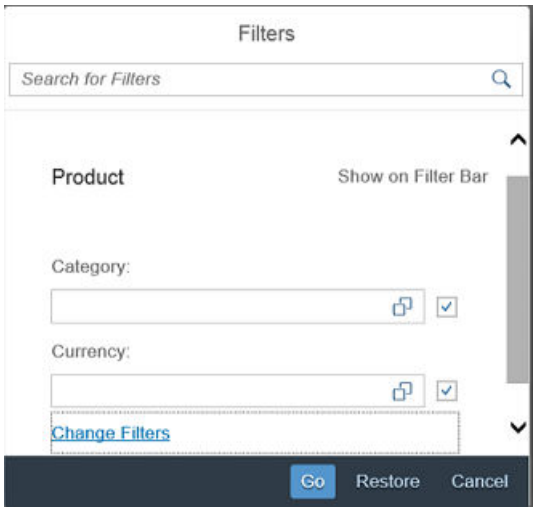

Figure 176: Currency Added to the Filter Bar

After selecting this additional field, we return to the table with the filter bar again and can use the value help for the newly added *Currency* field to restrict the results to those with *Currency = "EUR"*. Firing the query with this restriction, we see fewer results:

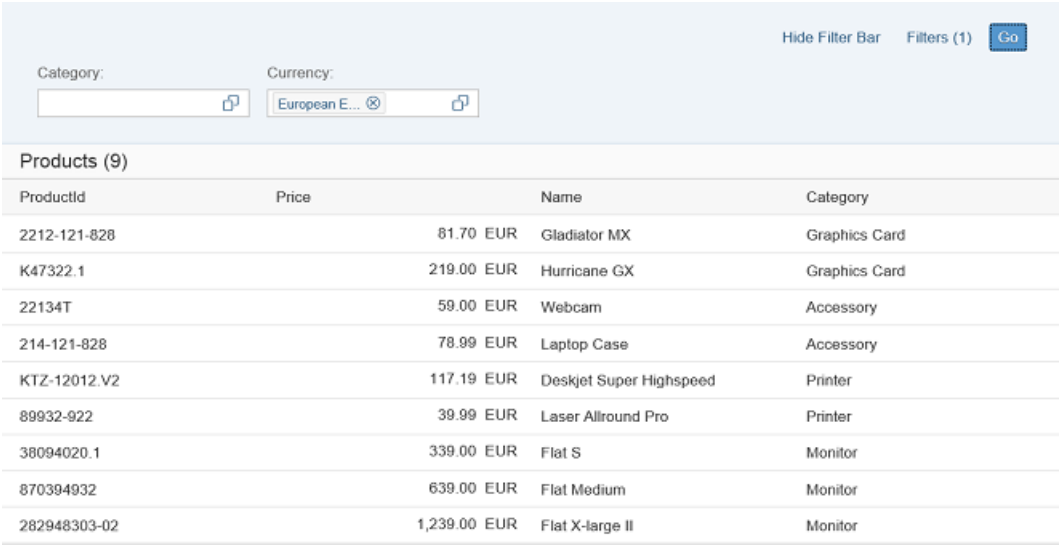

Figure 177: Query "EUR" Applied

Coding

You can view and download all files in the *Samples* in the Demo Kit at Smart Controls - Step 5 - Smart Filter Bar and Smart Table.

SmartTable.view.xml

```
<mvc:View
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    controllerName="sap.ui.demo.smartControls.SmartTable"
    xmlns:smartFilterBar="sap.ui.comp.smartfilterbar"
    xmlns:smartTable="sap.ui.comp.smarttable">
    <smartFilterBar:SmartFilterBar
        id="smartFilterBar"
        entitySet="Products">
        <smartFilterBar:controlConfiguration>
            <smartFilterBar:ControlConfiguration
                key="Category" visibleInAdvancedArea="true"
                preventInitialDataFetchInValueHelpDialog="false">
            </smartFilterBar:ControlConfiguration>
        </smartFilterBar:controlConfiguration>
    </smartFilterBar:SmartFilterBar>
    <smartTable:SmartTable
        id="smartTable_ResponsiveTable"
        smartFilterId="smartFilterBar"
        tableType="ResponsiveTable"
        editable="false"
        entitySet="Products"
        useVariantManagement="false"
        useTablePersonalisation="false"
        header="Products"
```

```
        showRowCount="true"
        useExportToExcel="false"
        enableAutoBinding="true">
    </smartTable:SmartTable>
</mvc:View>
```

We see that two new controls have been added to the `view.xml`. In the `SmartFilterBar` control we refer to an `entityType` which we will see later in `metadata.xml`. With the `ControlConfiguration` element that is added to the `controlConfiguration` aggregation of `SmartFilterBar`, we include the `Category` field in what we call the *Advanced* area of the filter bar. This is the area that can be hidden (or shown) using the toolbar *Hide Filter Bar*. We set the `preventInitialDataFetchInValueHelpDialog` property to `false` for an automatic execution of the query and thus showing of the results as soon as you open the value help. For `SmartTable` we define a few properties, some of which deserve special attention:

- `smartFilterId="smartFilterBar"`
  Ensures that the `SmartTable` can consume the `FilterBar` and the filter values defined there
- `tableType="ResponsiveTable"`
  Defines the underlying table as responsive (technically, it is an `sap.m.Table`)
- `useVariantManagement="false"`
  We will treat the case `true` in a later step.
- `useTablePersonalisation="false"`
  We will treat the case `true` in a later step.
- `header="Products"`
  Specifies the title for the table to be shown
- `showRowCount="true"`
  Specifies that the number of products appears after the title. In order for this count to work, the `SmartTable` needs to do the binding internally, which will be the case if either `smartFilterId` is specified or `enableAutoBinding` is set to `true` (see below).
- `useExportToExcel="false"`
  Offers an export to Microsoft Excel. In our case, we must set this value to `false` since the mock server does not support the proper format needed for such an export. The server must return a metadata document with `sap:supported-formats="xlsx"` to support this.
- `enableAutoBinding="true"`
  Defines whether the query is fired automatically initially, so `false` would mean the user must press *Go* to see any results in the table.

SmartTable.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function(Controller) {
    "use strict";
    return Controller.extend("sap.ui.demo.smartControls.SmartTable");
});
```

We notice that because the `enableAutoBinding` property has aready been set in the `view.xml`, we don't have to do any binding in the controller.

metadata.xml

```
<?xml version="1.0" encoding="utf-8"?>
<edmx:Edmx Version="1.0"
    xmlns:edmx="http://schemas.microsoft.com/ado/2007/06/edmx"

    </edmx:DataServices>
</edmx:Edmx>
```

The `LineItem` annotation used here defines the columns that are created in the table. Only records defined in this annotation are created as table columns. Apart from this annotation, we have seen the remaining part before: We have two `ValueList` annotations that trigger a value help to be created for the associated fields, in our case the `CurrencyCode` and the `Category`. For `EntityType Name="Product"`, we have defined two fields as filterable. These are the two fields on which you can filter (and that are then also available as filter fields for table personalization as we will see in the next step). For `EntityType Name="Currency"`, we have only defined the description to be filterable to ensure that we only see the description field as search field and not the `CurrencyCode` field. The same applies to `EntityType Name="Category"`.

Category.json

```
[{
    "CAT": "PRO",
    "DESCR": "Projector"
},
{
    "CAT": "GCD",
    "DESCR": "Graphics Card"
},
{
    "CAT": "ACC",
    "DESCR": "Accessory"
},
{
    "CAT": "PRI",
    "DESCR": "Printer"
},
{
    "CAT": "MON",
    "DESCR": "Monitor"
},
{
    "CAT": "LAP",
    "DESCR": "Laptop"
},
{
    "CAT": "KBD",
    "DESCR": "Keyboard"
}]
```

This JSON file defines the possible value of the `Category`.

Currency.json

```
[{
    "CURR": "EUR",
    "DESCR": "European Euro"
},
{
    "CURR": "USD",
    "DESCR": "United States Dollar"
},
{
    "CURR": "GBP",
```

```
    "DESCR": "British Pound"
},
{
    "CURR": "DKK",
    "DESCR": "Danish Krone"
},
{
    "CURR": "INR",
    "DESCR": "Indian Rupee"
},
{
    "CURR": "NOK",
    "DESCR": "Norwegian Krone"
},
{
    "CURR": "SEK",
    "DESCR": "Swedish Krona"
},
{
    "CURR": "CHF",
    "DESCR": "Swiss Franc"
}]
```

This JSON file defines the possible value of the `CurrencyCode`, the same values we saw in step 2.

Products.json

```
[
  {
    "ProductId": "1239102",
    "Name": "Power Projector 4713",
    "Category": "Projector",
    "SupplierName": "Titanium",
    "Description": "A very powerful projector with special features for Internet
usability, USB",
    "WeightMeasure": 1467,
    "WeightUnit": "g",
    "Price": 856.49,
    "CurrencyCode": "INR",
    "Status": "Available",
    "Quantity": 3,
    "UoM": "PC",
    "Width": 51,
    "Depth": 42,
    "Height": 18,
    "DimUnit": "cm"
  },
.
.
.
]
```

We have only listed a part of the `Products.json` entries since the actual values are not so relevant. Please note that for your convenience we have included additional properties in this file to make it easier to experiment with changes to the `metadata.xml`, and possibly of the `view.xml`, to allow for a more hands-on experience.

Related Information

Smart Filter Bar [page 2413]
Smart Table [page 2444]

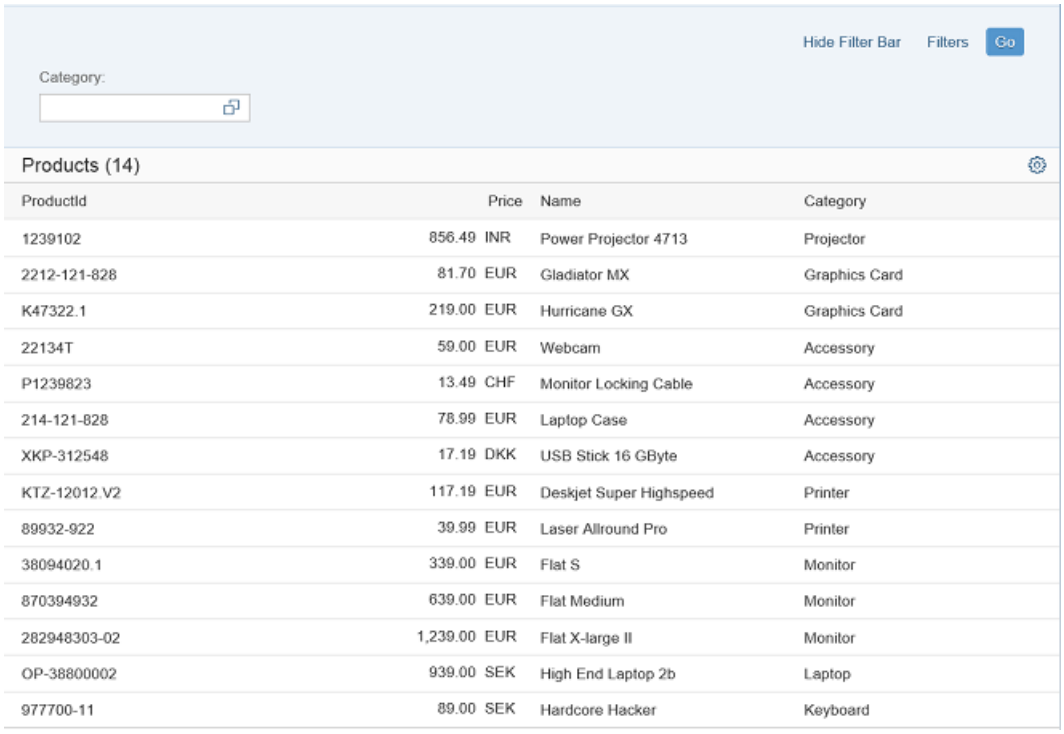
Step 6: Table Personalization

Table personalization offers you a dedicated dialog to specify which columns in the table are visible and in which order, how the data is sorted, whether grouping of the data is active, and whether table entries are filtered.

The settings in the dialog can also be persisted as you will see in the next step. In this step, we will use the same setup as in step 5 except that we enable table personalization in the `view.xml`.

Preview

Starting from the main UI, we can enter the different personalization possibilities by pressing the *Settings* icon in the upper right-hand corner of the toolbar:



ProductId	Price	Name	Category
1239102	856.49 INR	Power Projector 4713	Projector
2212-121-828	81.70 EUR	Gladiator MX	Graphics Card
K47322.1	219.00 EUR	Hurricane GX	Graphics Card
22134T	59.00 EUR	Webcam	Accessory
P1239823	13.49 CHF	Monitor Locking Cable	Accessory
214-121-828	78.99 EUR	Laptop Case	Accessory
XKP-312548	17.19 DKK	USB Stick 16 GByte	Accessory
KTZ-12012.V2	117.19 EUR	Deskjet Super Highspeed	Printer
89932-922	39.99 EUR	Laser Allround Pro	Printer
38094020.1	339.00 EUR	Flat S	Monitor
870394932	639.00 EUR	Flat Medium	Monitor
282948303-02	1,239.00 EUR	Flat X-large II	Monitor
OP-38800002	939.00 SEK	High End Laptop 2b	Laptop
977700-11	89.00 SEK	Hardcore Hacker	Keyboard

Figure 178: Table Personalization

After doing this, you see a popup with four different tabs:

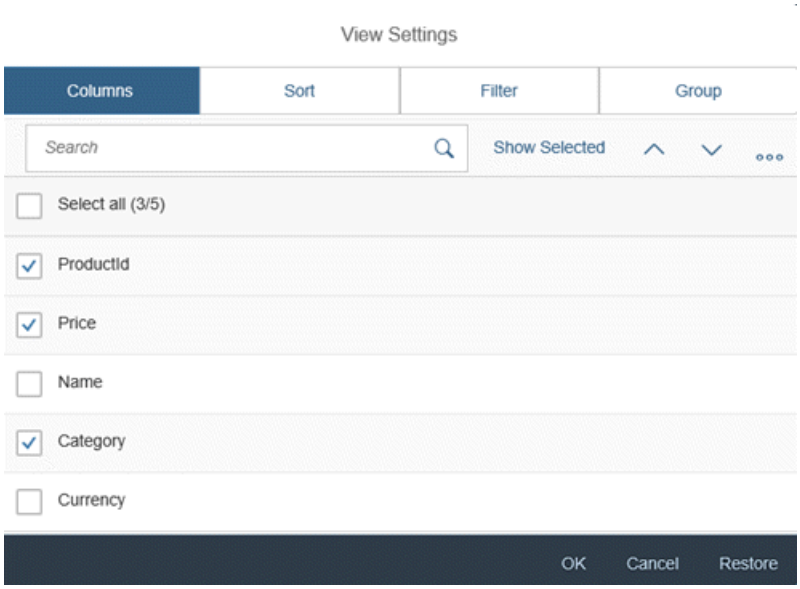


Figure 179: Settings Dialog: Column Visibility and Order

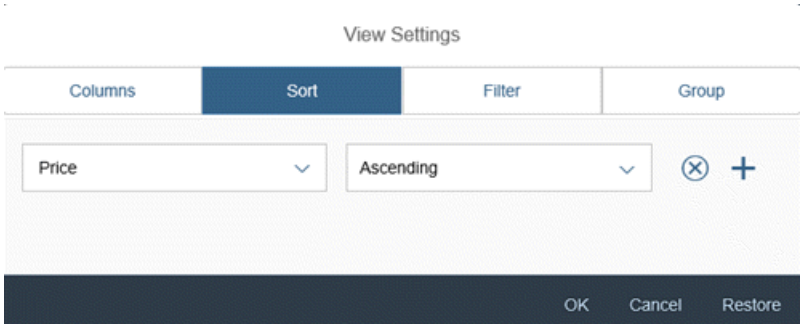

Figure 180: Settings Dialog: Sorting

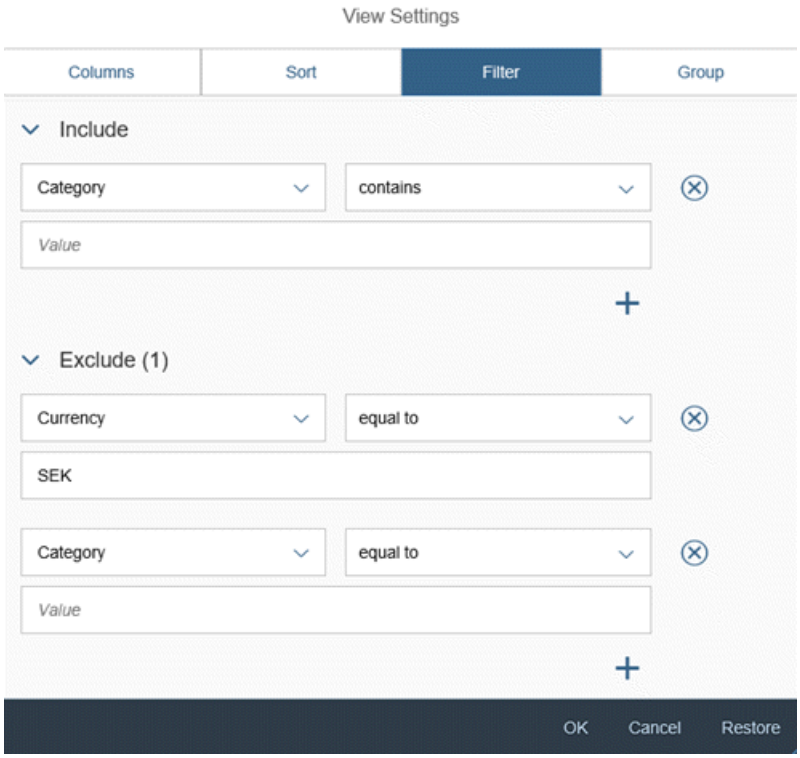

Figure 181: Settings Dialog: Filtering

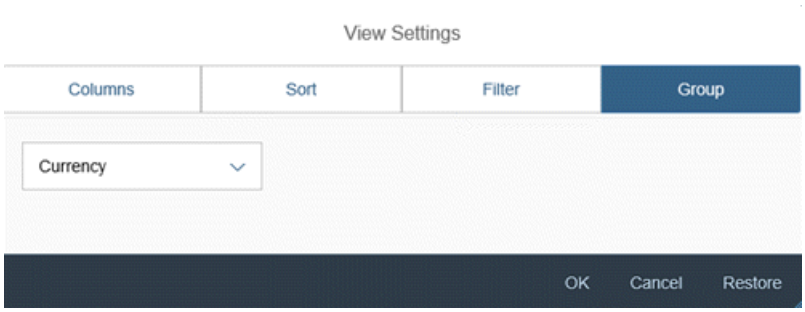

Figure 182: Settings Dialog: Grouping

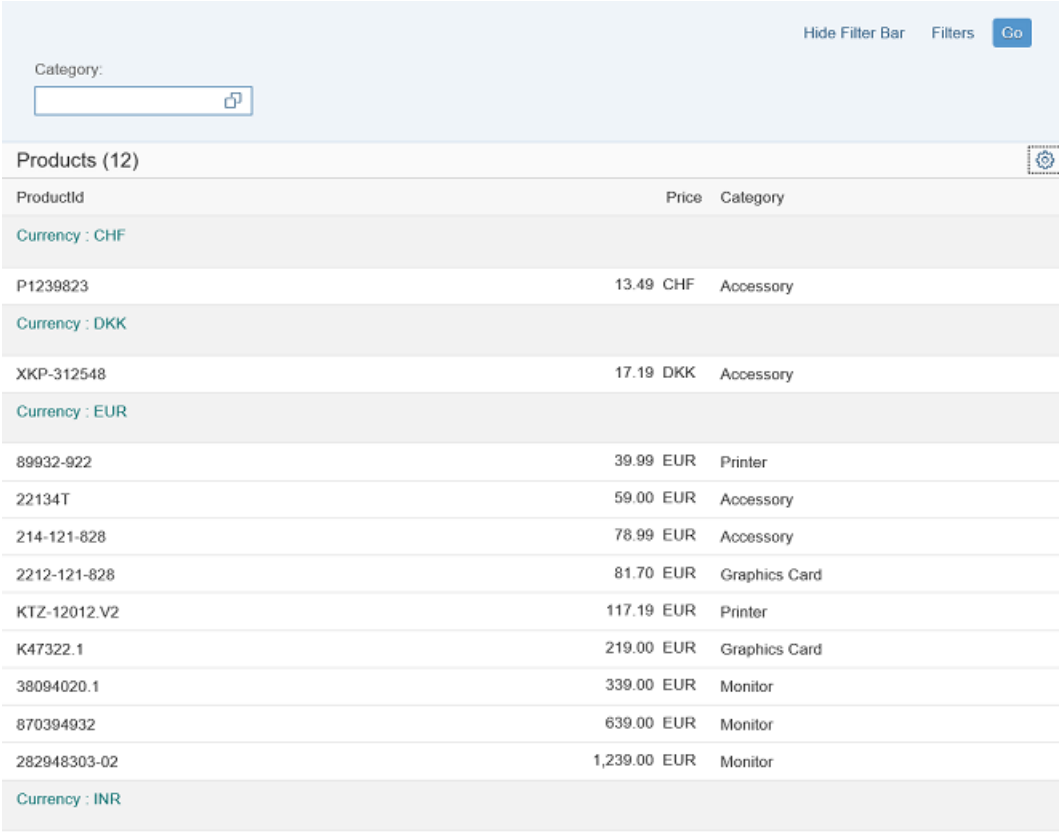

Figure 183: Resulting View with Personalization Applied

Coding

You can view and download all files in the *Samples* in the Demo Kit at Smart Controls - Step 6 - Table Personalization.

As mentioned above, we use the same content as in the previous step, so we refrain from any code listings except for the `view.xml`. We should mention, however, that fields that are not specifically marked as `sap:sortable="false"`, `sap:filterable="false"` or `sap:groupable="false"` in the metadata will all be sortable, filterable, or groupable, respectively, and thus be available in the tabs of the personalization dialog.

Personalization.view.xml

```
<mvc:View
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    controllerName="sap.ui.demo.smartControls.Personalization"
    xmlns:smartFilterBar="sap.ui.comp.smartfilterbar"
    xmlns:smartTable="sap.ui.comp.smarttable">
    <smartFilterBar:SmartFilterBar
        id="smartFilterBar"
        entitySet="Products">
        <smartFilterBar:controlConfiguration>
            <smartFilterBar:ControlConfiguration
                key="Category" visibleInAdvancedArea="true"
```

```
                preventInitialDataFetchInValueHelpDialog="false">
            </smartFilterBar:ControlConfiguration>
        </smartFilterBar:controlConfiguration>
    </smartFilterBar:SmartFilterBar>
    <smartTable:SmartTable
        id="smartTable_ResponsiveTable"
        smartFilterId="smartFilterBar"
        tableType="ResponsiveTable"
        editable="false"
        entitySet="Products"
        useVariantManagement="false"
        useTablePersonalisation="true"
        header="Products"
        showRowCount="true"
        useExportToExcel="false"
        enableAutoBinding="true">
    </smartTable:SmartTable>
</mvc:View>
```

To enable table personalization, we set `useTablePersonalisation` to `true`. As will become clear in the next section, you would typically use the table personalization together with view management since you can then also persist any changes done to the table.

Related Information

Personalization Dialog [page 2358]

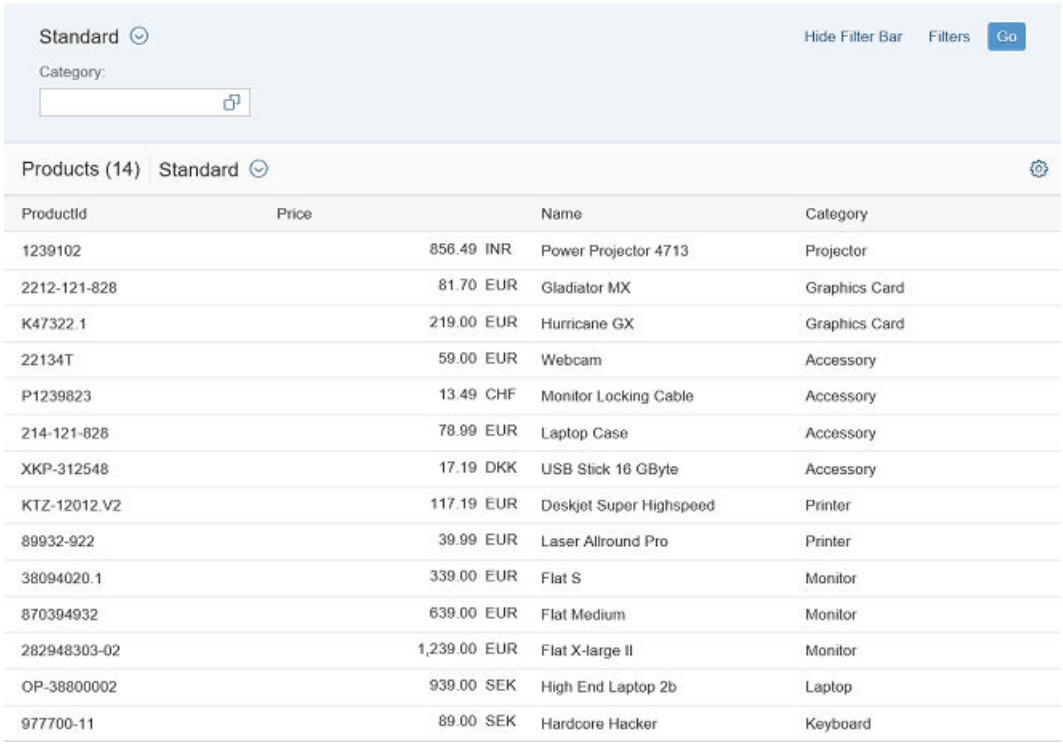
Step 7: View Management

The `VariantManagement` control allows you to handle views and makes it possible for the user to persist changes carried out on the UI and then later retrieve these changes.

For the smart controls, changes that are persisted include definitions of the filter used to query the results for the table and all changes done to the table with table personalization, visibility of columns and so on. Since we wish to provide stand-alone examples that can run on a local Web server, we do not connect to a real server on which the changes can be persisted so they can be retrieved later. Consequently, in our examples, changes are only kept in the current user session.

Preview

Initially, the UI looks as in the previous steps:



ProductId	Price	Name	Category
1239102	856.49 INR	Power Projector 4713	Projector
2212-121-828	81.70 EUR	Gladiator MX	Graphics Card
K47322.1	219.00 EUR	Hurricane GX	Graphics Card
22134T	59.00 EUR	Webcam	Accessory
P1239823	13.49 CHF	Monitor Locking Cable	Accessory
214-121-828	78.99 EUR	Laptop Case	Accessory
XKP-312548	17.19 DKK	USB Stick 16 GByte	Accessory
KTZ-12012.V2	117.19 EUR	Deskjet Super Highspeed	Printer
89932-922	39.99 EUR	Laser Allround Pro	Printer
38094020.1	339.00 EUR	Flat S	Monitor
870394932	639.00 EUR	Flat Medium	Monitor
282948303-02	1,239.00 EUR	Flat X-large II	Monitor
OP-38800002	939.00 SEK	High End Laptop 2b	Laptop
977700-11	89.00 SEK	Hardcore Hacker	Keyboard

Figure 184: Initial UI Without Personalization

We press *Filters* as shown in step 5 and then *Save* in the related dialog.

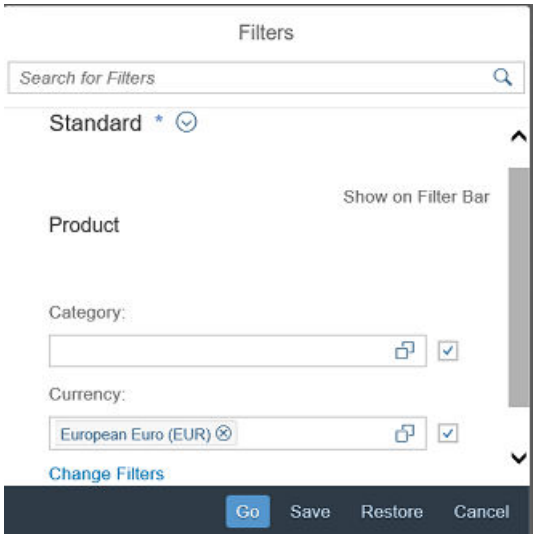


Figure 185: Specifying the Filter

After that, the following dialog is shown:

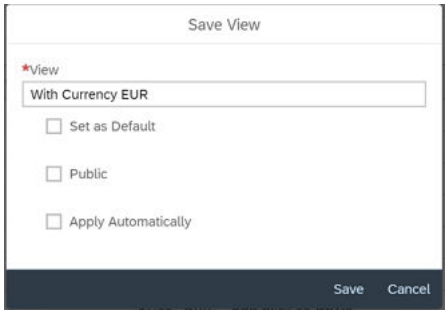

Figure 186: Defining the View Name

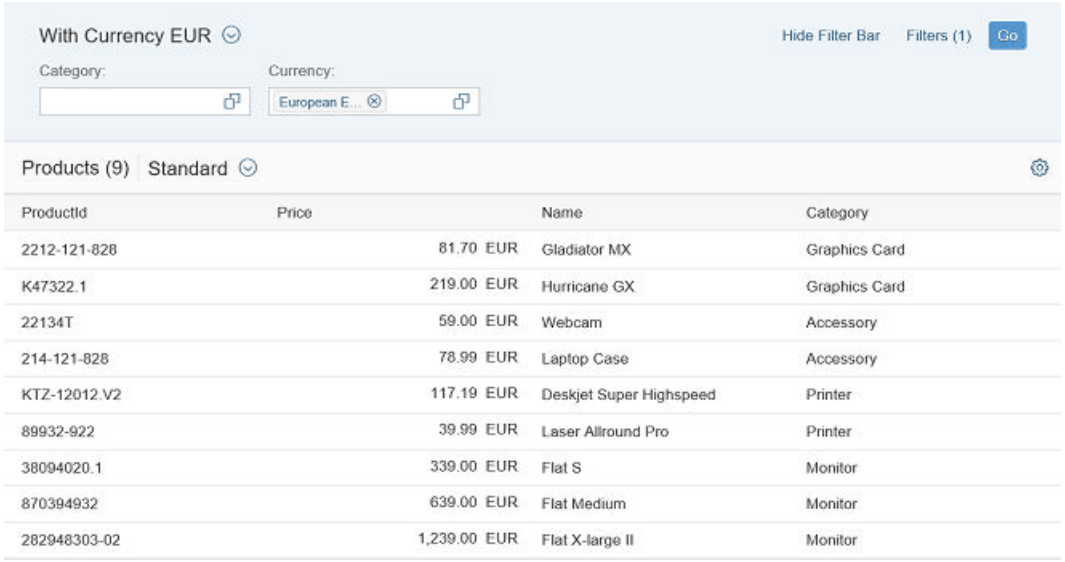
In this dialog, we specify the name under which this view is persisted, in our case `With Currency EUR`. With *Set as Default*, we can also specify whether this view is always used initially when navigating to this particular UI (since in our example we only persist within one browser session, this setting has no effect). With *Apply Automatically* we define that the query is fired automatically. The idea behind *Public* is that some popular but perhaps fairly complicated query settings that are used by several users can be automatically provided to all users. This *Public* option only has an effect when running on a real server and not on the mock server as in our example. If you choose *Public*, additional information regarding this function is required.

We verify these settings now and return to our main UI:



ProductId	Price	Name	Category
2212-121-828	81.70 EUR	Gladiator MX	Graphics Card
K47322.1	219.00 EUR	Hurricane GX	Graphics Card
22134T	59.00 EUR	Webcam	Accessory
214-121-828	78.99 EUR	Laptop Case	Accessory
KTZ-12012.V2	117.19 EUR	Deskjet Super Highspeed	Printer
89932-922	39.99 EUR	Laser Allround Pro	Printer
38094020.1	339.00 EUR	Flat S	Monitor
870394932	639.00 EUR	Flat Medium	Monitor
282948303-02	1,239.00 EUR	Flat X-large II	Monitor

Figure 187: UI with Active View

We notice that the *Currency* field is available in the filter bar and that we have already specified *EUR* as the currency.

Finally we now customize the table so that we do not see the `ProductId` column anymore. To do that, we press the *Settings* icon in the upper right-hand corner of the table and deselect `ProductId` in the dialog:

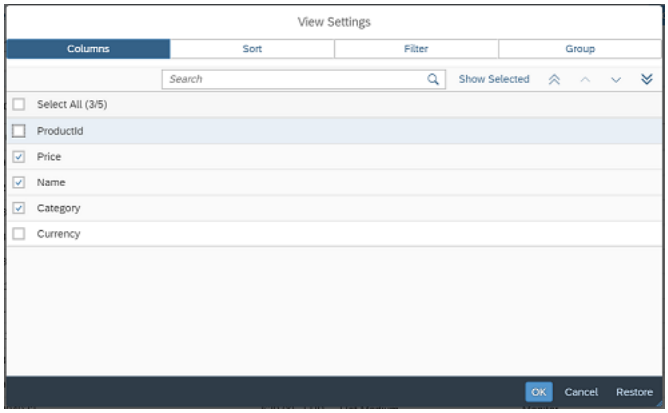


Figure 188: Remove `ProductId`

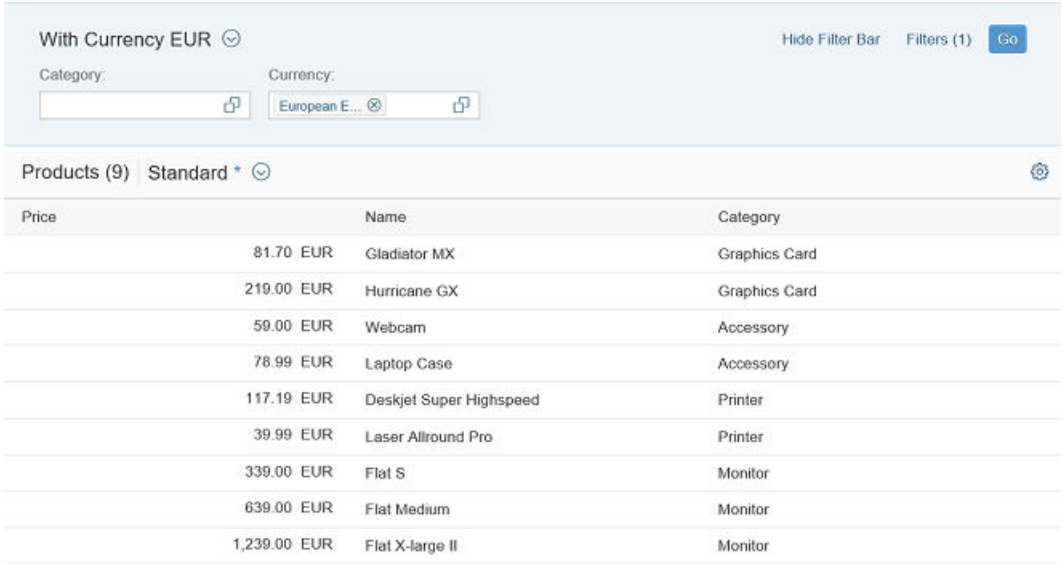
Returning to the main UI, we see that only the three columns required are now shown:



Price	Name	Category
81.70 EUR	Gladiator MX	Graphics Card
219.00 EUR	Hurricane GX	Graphics Card
59.00 EUR	Webcam	Accessory
78.99 EUR	Laptop Case	Accessory
117.19 EUR	Deskjet Super Highspeed	Printer
39.99 EUR	Laser Allround Pro	Printer
339.00 EUR	Flat S	Monitor
639.00 EUR	Flat Medium	Monitor
1,239.00 EUR	Flat X-large II	Monitor

Figure 189: Personalized Table

Figure 190:

The * right next to the *Standard* view indicates that a change has been made. We save this change by choosing the down-arrow symbol and *Save As* in the dialog, which takes us to a second dialog:

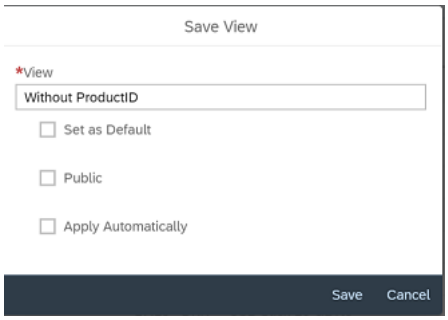


Figure 191: Specifying the View Name

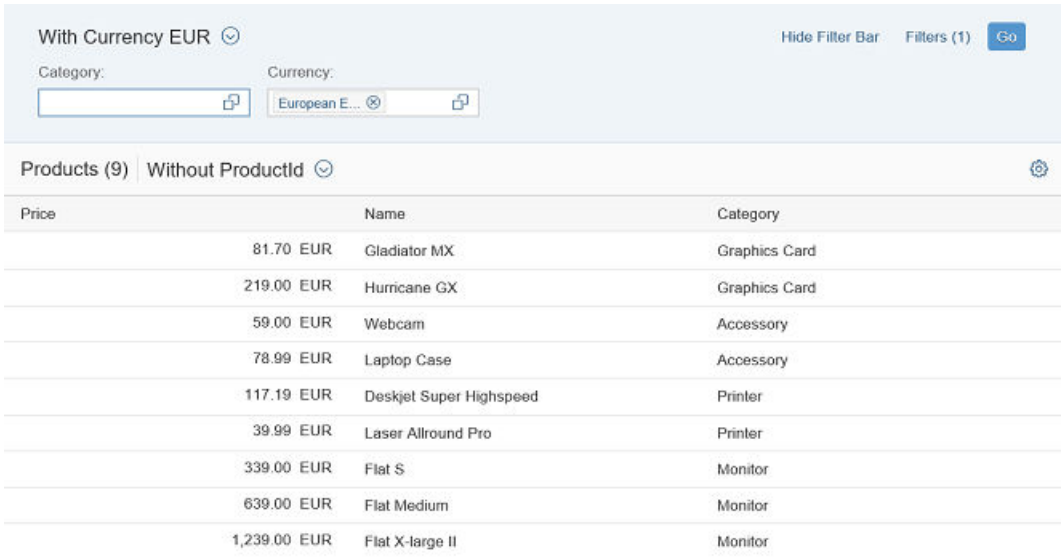
Also, here we have the possibility to set this as default and to share the view. The latter is similar to the view for the `SmartFilterBar` control. After confirming the specified name, you return directly to the main UI.



Price	Name	Category
81.70 EUR	Gladiator MX	Graphics Card
219.00 EUR	Hurricane GX	Graphics Card
59.00 EUR	Webcam	Accessory
78.99 EUR	Laptop Case	Accessory
117.19 EUR	Deskjet Super Highspeed	Printer
39.99 EUR	Laser Allround Pro	Printer
339.00 EUR	Flat S	Monitor
639.00 EUR	Flat Medium	Monitor
1,239.00 EUR	Flat X-large II	Monitor

Figure 192: View for the Filter Bar and View for the Table

Coding

You can view and download all files in the *Samples* in the Demo Kit at Smart Controls - Step 7 - Variant Management.

Since the coding is essentially identical with step 5 and step 6, we do not make any listing apart from the `view.xml` in which one property value has been changed and `persistencyKeys` have been specified.

VariantManagement.view.xml

```
<mvc:View
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    controllerName="sap.ui.demo.smartControls.VariantManagement"
```

```
    xmlns:smartFilterBar="sap.ui.comp.smartfilterbar"
    xmlns:smartTable="sap.ui.comp.smarttable">
    <smartFilterBar:SmartFilterBar
        id="smartFilterBar"
        entitySet="Products"
        persistencyKey="SmartFilterPKey">
        <smartFilterBar:controlConfiguration>
            <smartFilterBar:ControlConfiguration
                key="Category"
                visibleInAdvancedArea="true"
                preventInitialDataFetchInValueHelpDialog="false">
            </smartFilterBar:ControlConfiguration>
        </smartFilterBar:controlConfiguration>
    </smartFilterBar:SmartFilterBar>
    <smartTable:SmartTable
        id="smartTable_ResponsiveTable"
        smartFilterId="smartFilterBar"
        tableType="ResponsiveTable"
        editable="false"
        entitySet="Products"
        useVariantManagement="true"
        useTablePersonalisation="true"
        header="Products"
        showRowCount="true"
        useExportToExcel="false"
        enableAutoBinding="true"
        persistencyKey="SmartTablePKey">
    </smartTable:SmartTable>
</mvc:View>
```

Component.js

```
sap.ui.define([
    "sap/ui/core/UIComponent",
    "sap/ui/fl/FakeLrepConnectorLocalStorage"
], function (UIComponent, FakeLrepConnectorLocalStorage) {
    "use strict";
    return UIComponent.extend("sap.ui.demo.smartControls.Component", {
        metadata: {
            manifest: "json"
        },
        init: function () {

FakeLrepConnectorLocalStorage.enableFakeConnector(sap.ui.require.toUrl("sap/ui/
demo/smartControls/lrep/component-test-changes.json"));
            UIComponent.prototype.init.apply(this, arguments);
        },
        destroy: function () {
            FakeLrepConnectorLocalStorage.disableFakeConnector();
            UIComponent.prototype.destroy.apply(this, arguments);
        }
    });
});
```

We add `FakeLrepConnectorLocalStorage` to our `Component.js` to enable the local storage, which is used by the `VariantManagement` control to save the client-side settings.

Related Information

Smart Variant Management [page 2457]

Step 8: Page Variant Management

In this step, we will look at the page variant of the `VariantManagement` control, an enhanced function of the `SmartVariantManagement` control that can handle multiple smart controls.

Basically, the paged version of the `VariantManagement` control is the same as the (non-paged) `VariantManagement` control. The difference is that the page variant is initialized with the `persistencyKey` property and can handle the persistency of multiple smart controls. Each smart control that uses personalization via the page variant has to provide a persistency key. The persistency itself will be stored under the `persistencyKey` of the `VariantManagement` control, and the relevant content for each control will be distributed accordingly based on each individual persistency key.

`persistencyKey` - `VariantManagement` control

- `persistencyKey` - `SmartFilterBar` control-relevant content
- `persistencyKey` `SmartTable` control-relevant content

Therefore, the persistent content of the page variant is the aggregated content of each registered smart control, and the individual persistency keys of the various smart controls are used to distinguish and distribute the relevant content.

Preview

As a page variant, the view management is now no longer part of the `SmartFilterBar` and `SmartTable` controls, but displayed in a central location instead:

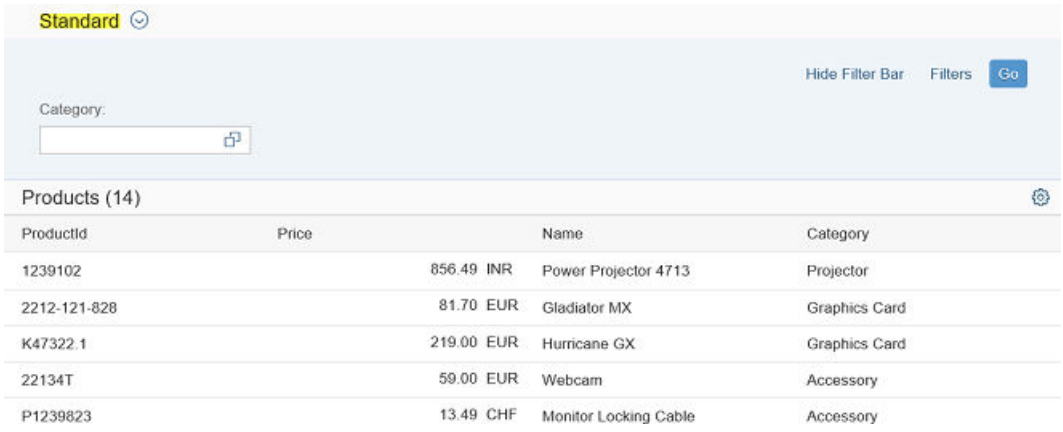


Figure 193: Central View Management

In addition, the `VariantManagement` control is no longer displayed in the *Filter* dialog of the `SmartFilterBar` control:

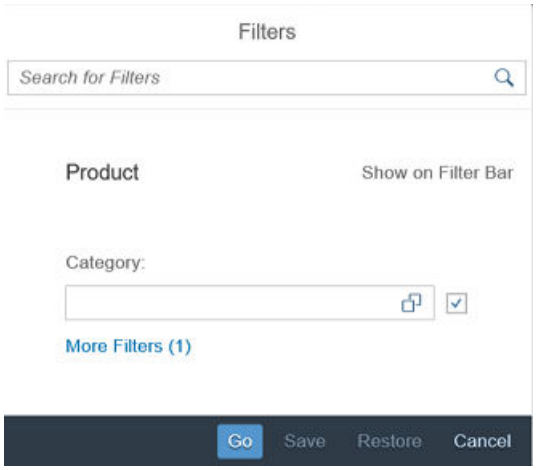

Figure 194: Filter Dialog Without View Management

Other than that, the page variant is just the same as the `VariantManagement` control.

Coding

You can view and download all files in the *Samples* in the Demo Kit at Smart Controls - Step 8 - Page Variant Management .

VariantManagement.view.xml

```
<mvc:View
          xmlns="sap.m"
       xmlns:mvc="sap.ui.core.mvc"
       controllerName="sap.ui.demo.smartControls.VariantManagement"
       xmlns:smartFilterBar="sap.ui.comp.smartfilterbar"
       xmlns:smartTable="sap.ui.comp.smarttable">
       <smartFilterBar:SmartFilterBar
             id="smartFilterBar"
             entitySet="Products"
             persistencyKey="SmartFilterPKey">
             <smartFilterBar:controlConfiguration>
                   <smartFilterBar:ControlConfiguration
                         key="Category"
                         visibleInAdvancedArea="true"
                         preventInitialDataFetchInValueHelpDialog="false">
                   </smartFilterBar:ControlConfiguration>
             </smartFilterBar:controlConfiguration>
       </smartFilterBar:SmartFilterBar>
       <smartTable:SmartTable
             id="smartTable_ResponsiveTable"
             smartFilterId="smartFilterBar"
             tableType="ResponsiveTable"
             editable="false"
             entitySet="Products"
```

```
            useVariantManagement="true"
            useTablePersonalisation="true"
            header="Products"
            showRowCount="true"
            useExportToExcel="false"
            enableAutoBinding="true"
            persistencyKey="SmartTablePKey">
        </smartTable:SmartTable>
</mvc:View>
```

The example shows the view management **without** a page variant.

VariantManagement.view.xml

```
<mvc:View
           controllerName="sap.ui.demo.smartControls.VariantManagement"
       xmlns="sap.m"
       xmlns:mvc="sap.ui.core.mvc"
       xmlns:html="http://www.w3.org/1999/xhtml"
       xmlns:smartVariantManagement="sap.ui.comp.smartvariants"
       xmlns:smartFilterBar="sap.ui.comp.smartfilterbar"
       xmlns:smartTable="sap.ui.comp.smarttable">
       <HBox
class="exPageVariantPadding">
       <smartVariantManagement:SmartVariantManagement
             id="pageVariantId"
             persistencyKey="PageVariantPKey" />
       </HBox>
       <smartFilterBar:SmartFilterBar
             id="smartFilterBar"
             entitySet="Products"
             smartVariant="pageVariantId"
             persistencyKey="SmartFilterPKey"
assignedFiltersChanged="onFiltersChanged">
             <smartFilterBar:controlConfiguration>
                   <smartFilterBar:ControlConfiguration
                         key="Category"
                         visibleInAdvancedArea="true"
                         preventInitialDataFetchInValueHelpDialog="false">
                   </smartFilterBar:ControlConfiguration>
             </smartFilterBar:controlConfiguration>
       </smartFilterBar:SmartFilterBar>
       <smartTable:SmartTable
             id="smartTable_ResponsiveTable"
             smartFilterId="smartFilterBar"
             smartVariant="pageVariantId"
             tableType="ResponsiveTable"
             editable="false"
             entitySet="Products"
             useVariantManagement="true"
             useTablePersonalisation="true"
             header="Products"
             showRowCount="true"
             useExportToExcel="false"
             enableAutoBinding="true"
             persistencyKey="SmartTablePKey">
       </smartTable:SmartTable>
</mvc:View>
```

The example shows the view management **with** a page variant.

Step 9: Smart Chart with Chart Personalization and View Management

In this step, we will look at the `SmartChart` control with the chart personalization and in combination with the `VariantManagement` control that allow you to use complex graphics along with other smart control features.

The `SmartChart` control can be used for visualizing data in a graphical manner. The `SmartChart` control creates a chart based on OData metadata and the configuration data that has been specified. The `entitySet` property must be specified to use the control. This property is used to fetch fields from OData metadata, from which the chart UI is generated.

There are several features that can be enabled in `SmartChart`, but for this tutorial, we will have a look at the following features:

- Chart personalization
- View management support
- Semantic object navigation using `SemanticObjectController`

Preview

This is what the smart chart looks like initially after firing the query:

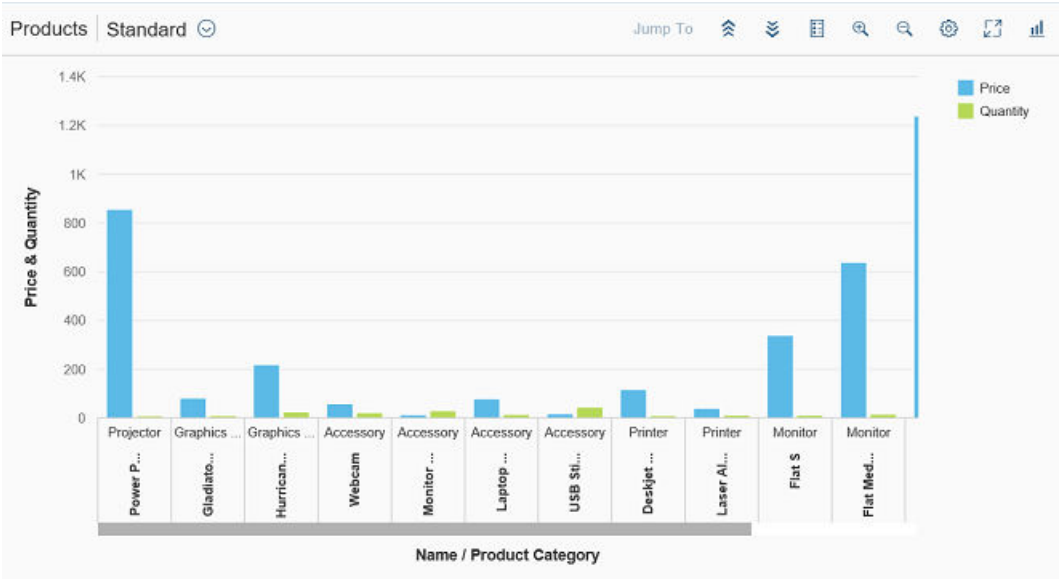

Figure 195: Initial Look of Smart Chart after Firing Query

The toolbar of the smart chart contains the header, and next to it is the view management dialog that has been explained in detail in one of the previous steps.

Next to the view management dialog is a button labeled *Jump To*. This button is disabled by default, but once a column has been selected inside the chart, this button gets enabled. When we click this button, a popup appears that contains details of the selected column. You can also navigate to related apps from here. This feature is enabled using `SemanticObjectController`. When we hover the mouse pointer over a column, a popup is displayed to provide additional information.

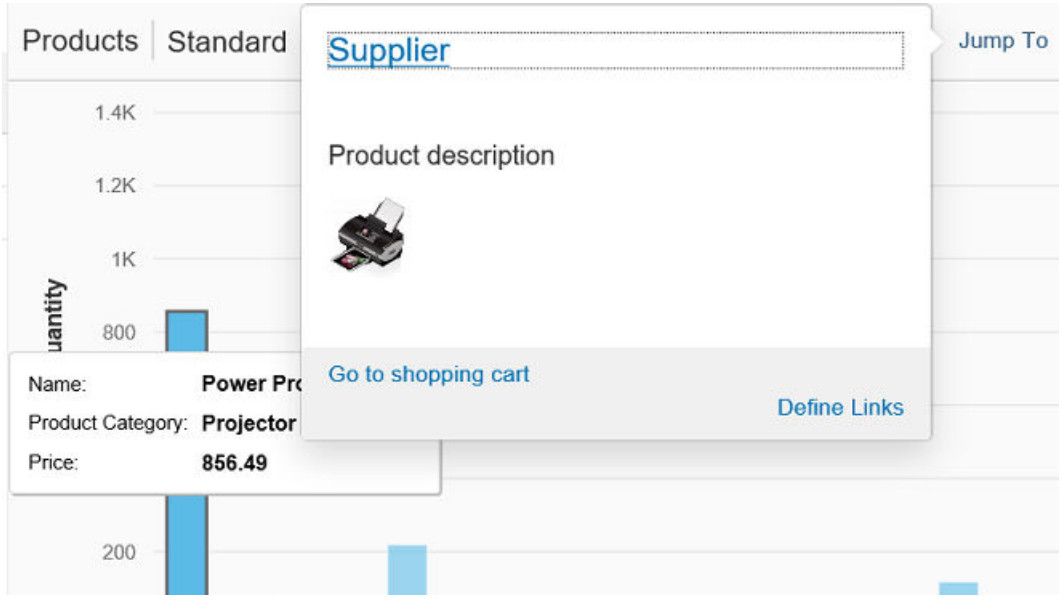

Figure 196: Semantic Navigation Feature

The button at the right-hand side of the toolbar can be used for selecting the chart type:

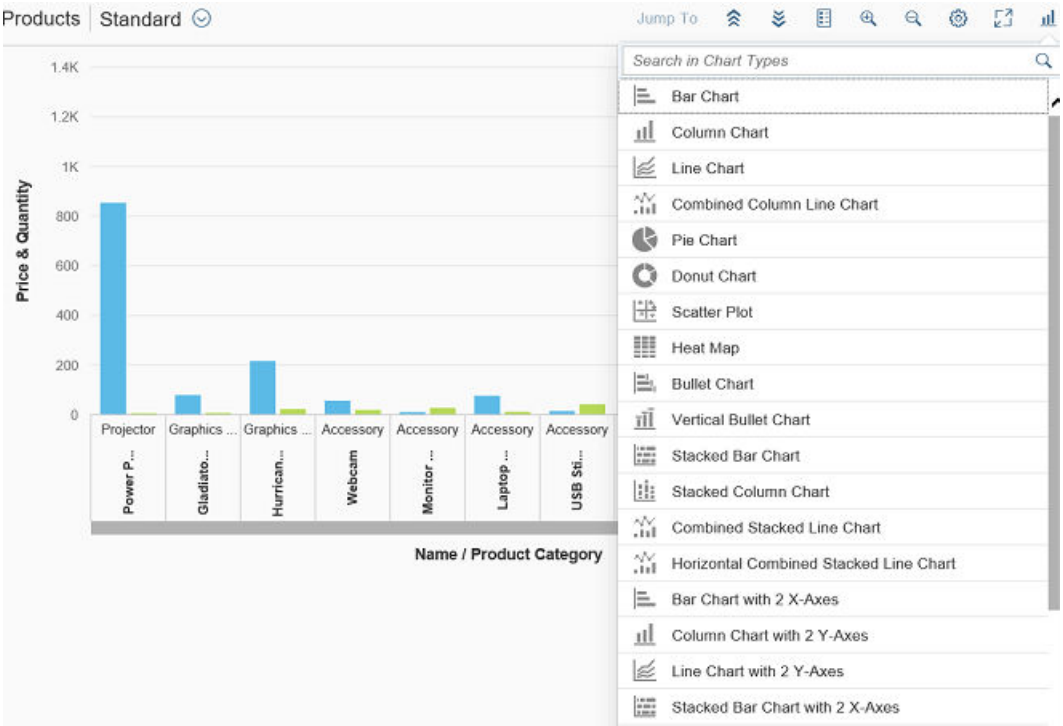

Figure 197: Selection of Chart Type

The two buttons next to the *Jump To* button can be used to drill up and drill down into the chart. Using this feature you can display even more detailed information in the chart:

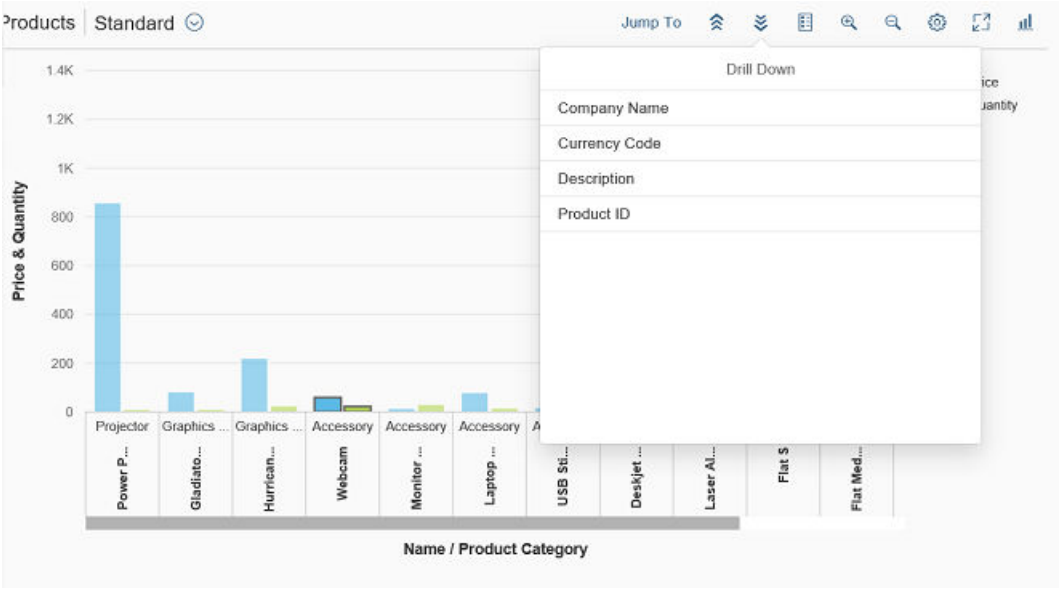

Figure 198: Drillup and Drilldown Features

If we set the `showDetailsButton` and `showDrillBreadcrumbs` properties to `true`, we can also use an alternative drilldown function: A button labeled *Drilldown* is shown. If a column is selected inside the chart, this button changes into a *Details* button. When you click this button, again, a popup appears that contains details of the selected column.

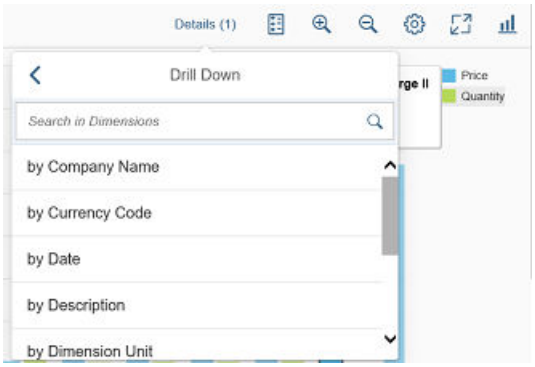

Figure 199: Drilldown by Dimensions

When you drill further down, you can see the breadcrumbs trail for the drilldown path on the left-hand side, which you can also use to drill up within the chart.

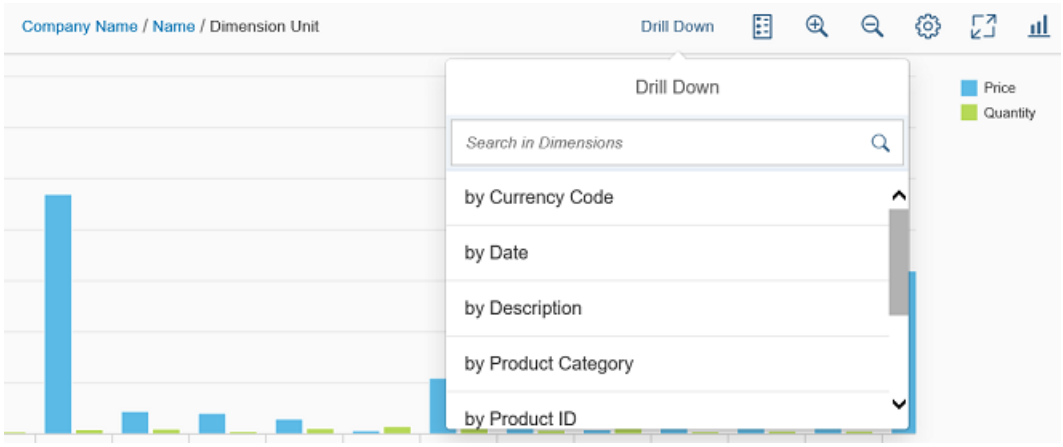

Figure 200: Further Drilldown

The next button can be used to toggle legend visibility:

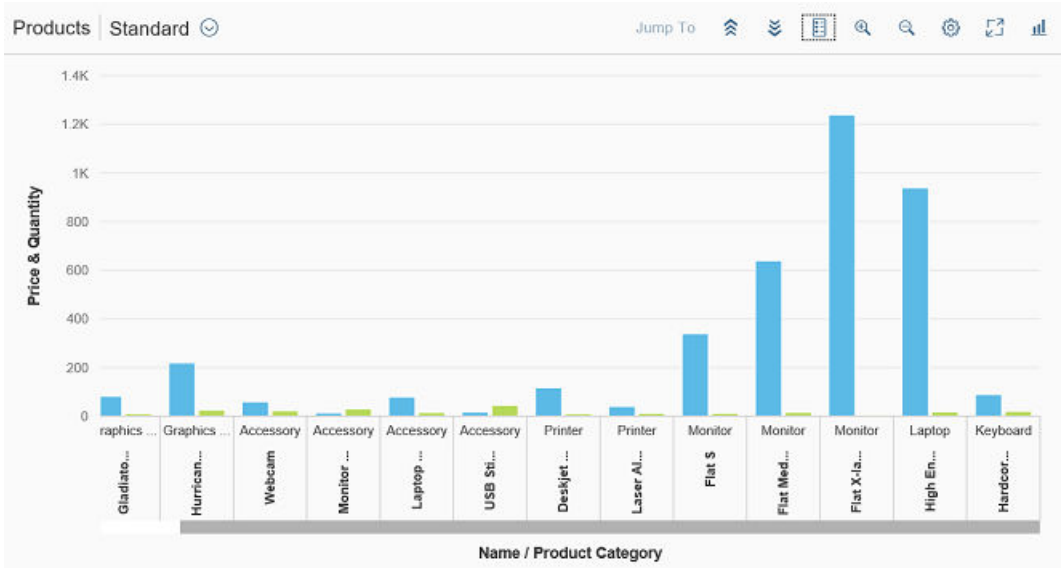

Figure 201: Toggle Legend Visibility

The two buttons next to this in the toolbar are used for zooming in or out. This will help you to get a clearer picture of a particular entity. The next button in the toolbar is the *Settings* icon that opens the personalization dialog for the chart:

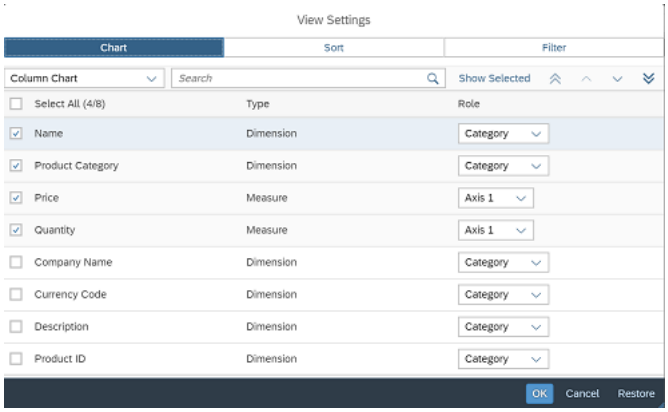

Figure 202: Dialog for Adding Measures and Dimensions

The button next to the settings can be used to display a chart in full screen mode. The chart will then take up 100 % width and height of the browser.

Coding

You can view and download all files in the *Samples* in the Demo Kit at Smart Controls - Step 9 - Smart Chart and at Samples.

SmartChart.view.xml

```
<mvc:View xmlns="sap.m" xmlns:mvc="sap.ui.core.mvc"
    xmlns:html="http://www.w3.org/1999/xhtml"
    xmlns:app="http://schemas.sap.com/sapui5/extension/sap.ui.core.CustomData/1"
    controllerName="sap.ui.demo.smartControls.SmartChart"
xmlns:sl="sap.ui.comp.navpopover"
    xmlns:smartChart="sap.ui.comp.smartchart">
    <smartChart:SmartChart enableAutoBinding="true"
        entitySet="Products" useVariantManagement="true"
        persistencyKey="SmartChart_Explored" useChartPersonalisation="true"
        header="Products">
        <smartChart:semanticObjectController>
            <sl:SemanticObjectController
                navigationTargetsObtained="onNavigationTargetsObtained"
navigate="onNavigate" />
        </smartChart:semanticObjectController>
    </smartChart:SmartChart>
</mvc:View>
```

We see that a new control has been added to the `view.xml`. In the `SmartChart` control, we refer to the entity type that we will see later in the `metadata.xml`. With `SemanticObjectController` that is added to the `semanticObjectController` aggregation of `SmartChart`, we can enable the display of linked data for a particular entity. We also set `enableAutoBinding="true"`, which enables automatic execution of the query

and thus shows the result as soon as the `SmartChart` control is loaded. We set `useVariantManagement="true"` and `persistencyKey="SmartChart_Explored"` to enable the view management. We also set `useChartPersonalisation="true"`, which enables the chart personalization.

SmartChart.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageBox"
], function(Controller, MessageBox) {
    "use strict";
    return Controller.extend("sap.ui.demo.smartControls.SmartChart", {
        onNavigationTargetsObtained: function(oEvent) {
            var oParameters = oEvent.getParameters();
            var oSemanticAttributes = oParameters.semanticAttributes;
            oParameters.show("Supplier", new sap.ui.comp.navpopover.LinkData({
                text: "Homepage",
                href: "http://www.sap.com",
                target: "_blank"
            }), [
                new sap.ui.comp.navpopover.LinkData({
                    text: "Go to shopping cart"
                })
            ], new sap.ui.layout.form.SimpleForm({
                maxContainerCols: 1,
                content: [
                    new sap.ui.core.Title({
                        text: "Product description"
                    }), new sap.m.Image({
                        src: "img/HT-1052.jpg", //
oSemanticAttributes.ProductPicUrl,
                        densityAware: false,
                        width: "50px",
                        height: "50px",
                        layoutData: new sap.m.FlexItemData({
                            growFactor: 1
                        })
                    }), new sap.m.Text({
                        text: oSemanticAttributes.Description
                    })
                ]
            }));
        },
        onNavigate: function(oEvent) {
            var oParameters = oEvent.getParameters();
            if (oParameters.text === "Homepage") {
                return;
            }
            MessageBox.show(oParameters.text + " has been pressed", {
                icon: sap.m.MessageBox.Icon.INFORMATION,
                title: "SmartChart demo",
                actions: [
                    sap.m.MessageBox.Action.OK
                ]
            });
        }
    });
});
```

The following two functions are defined:

- `onNavigationTargetObtained()`
- `onNavigate()`

`onNavigationTargetObtained()` is called when a column is selected and you click the *Jump To* button. With the click event the semantic parameters are obtained, and the function renders a navigation popover containing a simple form that presents detailed information of the entity selected as can be seen in figure 2.

`onNavigate()` is called when the links in the navigation popover are clicked. This is done to demonstrate how you add more functionality to the data in the navigation popover. In our example, we are just showing a message box and the navigation to one other link.

metadata.xml

```
<?xml version="1.0" encoding="utf-8"?>
<edmx:Edmx Version="1.0"
    xmlns:edmx="http://schemas.microsoft.com/ado/2007/06/edmx"

                            <Collection>
                                <PropertyPath>Name</PropertyPath>
                                <PropertyPath>Category</PropertyPath>
```

```
                        </Collection>
                    </PropertyValue>
                    <PropertyValue Property="Measures">
                        <Collection>
                            <PropertyPath>Price</PropertyPath>
                            <PropertyPath>Quantity</PropertyPath>
                        </Collection>
                    </PropertyValue>
                </Record>
            </Annotation>
        </Annotations>
        <Annotations Target="com.sap.wt08.Product/Category"
            xmlns="http://docs.oasis-open.org/odata/ns/edm">
            <Annotation Term="com.sap.vocabularies.Common.v1.SemanticObject"
                String="SemanticObjectCategory" />
        </Annotations>
    </Schema>
  </edmx:DataServices>
</edmx:Edmx>
```

The most important point to keep in mind is that analytical annotations along with chart annotations need to exist in the `metadata.xml`. The most prominent annotations are listed below:

- `sap:semantics="aggregate"`
  An analytical operation can be performed on the data. This has to be added to `EntityType` (in our case "Product")
- `sap:aggregation-role="dimension"`
  Defines that a property of `EntityType` is treated as a dimension.
- `sap:aggregation-role="measure"`
  Defines that a property of `EntityType` is treated as a measure.
- `Annotation Term="com.sap.vocabularies.UI.v1.Chart`
  Defines the UI annotation for rendering a chart.
- `EnumMember="com.sap.vocabularies.UI.v1.ChartType/Column"`
  Defines the default chart type.
- `Annotation Term="com.sap.vocabularies.Common.v1.SemanticObject"`
  Defines the `SemanticObject` annotation for `EntityType` (in our case the product category).

Products.json

```
[
  {
    "ProductId": "1239102",
    "Name": "Power Projector 4713",
    "Category": "Projector",
    "SupplierName": "Titanium",
    "Description": "A very powerful projector with special features for Internet
usability, USB",
    "WeightMeasure": 1467,
    "WeightUnit": "g",
    "Price": 856.49,
    "CurrencyCode": "EUR",
    "Status": "Available",
    "Quantity": 3,
    "UoM": "PC",
    "Width": 51,
    "Depth": 42,
    "Height": 18,
```

```
    "DimUnit": "cm"
  },
.
.
.
]
```

We have only listed a part of the `Products.json` entries since the actual values are not so relevant. Please note that for your convenience we have included additional properties in this file to make it easier to experiment with changes of the `metadata.xml`, and possibly of the `view.xml`, to allow for a more hands-on experience.

Summary

Summary of the *Smart Controls* tutorial

In this tutorial we have focused on conveying the big picture of the smart controls leaving quite a few features of the smart controls aside. For example, the `SmartTable` control can also be used in combination with the so-called analytical table, a table type that has additional features, such as displaying aggregation rows to display the sums. This information is controlled by the configuration in the `metadata.xml` document. In addition, the `SmartField` control as a basic building block can consume more annotations than we have been able to show here.

We would also like to mention that the OData services you have seen in this tutorial have version 2.0. With version 4.0, the behavior might change.

In the previous steps you have seen how smart controls can use different sources of configuration to make development easier. You may wonder, though, where exactly which configuration should be located. To answer this question, we need to think about from where the various configuration parts are coming. You should think of `metadata.xml` (that is the definition of entities, such as `EntityType` and annotations) as information associated with the service or the application logic, even though we have seen that annotations are more UI-specific than the more generic information found in the `EntityTypes` and the `EntityContainer`. Information in the `metadata.xml` is therefore predetermined for a certain amount of reuse: You can build several UIs (or parts of it) reusing this information. We have seen such a reuse several times in this document: The reuse of the OData service metadata document for `SmartFilterBar`, `SmartTable`, and the popups associated with the value help. In contrast to this, the configuration information that we specify in the `view.xml` is more specific to one concrete UI.

3D Viewer

In this tutorial, you will learn how to work with the controls in the Visual Interaction toolkit (`sap.ui.vk` library) to create applications with 3D viewing functionality.

> ⚠ Caution
>
> The controls in the `sap.ui.vk` library are currently flagged as experimental. For more information, see Compatibility Rules [page 17].

The Visual Interaction toolkit provides controls for the visualization of 3D models in your application.

→ Tip

You do not have to do the tutorial steps sequentially. You can start the tutorial at any step you want, but you just need to ensure that you have downloaded all the relevant code required to work through the step.

You can view and download the files for all steps at 3D Viewer.

For more information check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]

Prerequisites

Prerequisite steps for the 3D Viewer tutorial.

⚠ Caution

The controls in the `sap.ui.vk` library are currently flagged as experimental. For more information, see Compatibility Rules [page 17].

Before proceeding with the 3D Viewer tutorial, ensure that you are familiar with the concepts introduced in the following tutorials:

- Walkthrough [page 69]
- Data Binding [page 219]

File Structure

Please note that for each step in this tutorial, you will be creating a separate folder with its own copy of the following files:

- **<FolderName>** (folder)
  - controller (folder)
    - `App.controller.js`
  - i18n (folder)
    - `i18n.properties`
  - view (folder)
    - `App.view.xml`
  - `Component.js`
  - `index.html`
  - `manifest.json`

Step 1: 3D Viewer With Single File Loading

In this step, you will be creating a 3D Viewer application that allows a user to load a single 2D image or 3D model that is stored locally or remotely.

> ⚠ Caution
>
> The controls in the `sap.ui.vk` library are currently flagged as experimental. For more information, see Compatibility Rules [page 17].

Preview

By the end of this step, you will have created a Viewer application that allows you to load a 2D or 3D resource. The Viewer application will look as follows:

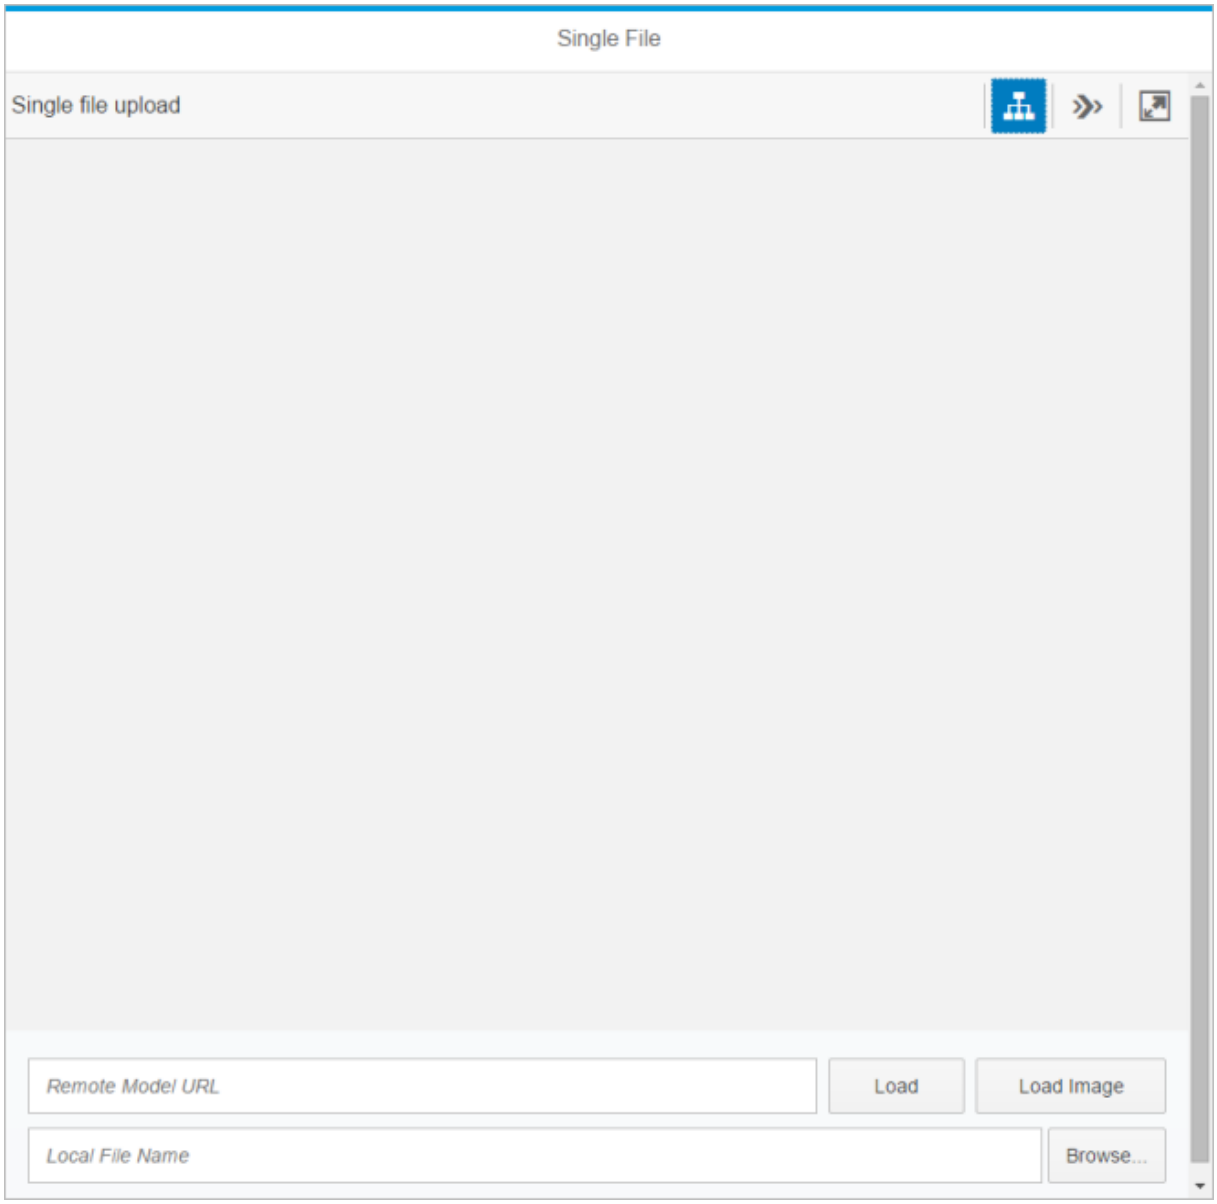

Figure 203: Viewer application with single file loading functionality

Coding

You can view and download all files at 3D Viewer - Step 1 - Single File.

index.html

In the first `script` element of this `index.html` file, we are referencing:

- the `sap.ui.vk` library, which contains the controls for adding 3D visualization functionality (the `sap.ui.vk` value in the `data-sap-ui-libs` property)
- the component file called `Component.js` (the `data-sap-ui-resourceroots` property)

We specify that resources related to `singleFile` are located in the same folder as this `index.html` file.

In the second `script` element, we create a function that will be called as soon as SAPUI5 is loaded and initialized. We add our application into this function.

```
<!DOCTYPE HTML>
<html>
    <head>
        <meta http-equiv="X-UA-Compatible" content="IE=edge">
        <meta http-equiv="Content-Type" content="text/html;charset=UTF-8"/>
    <script id="sap-ui-bootstrap"
        src="../../../../../../../../../resources/sap-ui-core.js"
        data-sap-ui-libs="sap.ui.vk, sap.m"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-bindingSyntax="complex"
        data-sap-ui-resourceroots='{
            "singleFile": "./"
         }' >
    </script>
    <script>
    sap.ui.getCore().attachInit(function(){
        new sap.m.Shell({
            app: new sap.ui.core.ComponentContainer({
                name : "singleFile"
            })
        }).placeAt("content");
    });
    </script>
    </head>
    <body id="content" class="sapUiBody">
    </body>
</html>
```

Component.js

In the `Component.js` file, the only item for you to consider is to reference is the `manifest.json` file.

```
sap.ui.define([
    "sap/ui/core/UIComponent"
], function (UIComponent) {
    "use strict";
    return UIComponent.extend("singleFile.Component", {
        metadata: {
            manifest: "json"
        },
        init: function () {
            // call the init function of the parent
            UIComponent.prototype.init.apply(this, arguments);
        }
    });
});
```

i18n.properties

The `i18n.properties` file contains all the user interface labels for the application, which includes the labels for he toolbar, the page title, the buttons, the text input fields, and the error message that will be displayed when no URL is specified.

```
# App Descriptor
appTitle=App title
appDescription=This is a description coming from the i18n as specified in
manifest.json
# Viewer Descriptor
viewerToolbarTitle=Single file load
# Page Descriptor
pageTitle=Single File
```

```
# Form Descriptor
formRemoteURL=Remote Model URL
buttonLoadModel=Load
buttonLoadImage=Load Image
formLocalFileName=Local File Name
# Message Toast
missingUrl=Please specify a URL
```

manifest.json

The `manifest.json` file contains information about the files that we need to use in our application.

In this file, we reference the `i18n.properties` file to specify what language the user interface of our application will have. We also specify what the root view of the application is; i.e. the page that is loaded first when the application is first started. This is set in the `rootView` property.

```
{
  "_version": "1.8.0",
  "sap.app": {
    "id": "singleFile",
    "type": "application",
    "i18n": "i18n/i18n.properties",
    "title": "{{appTitle}}",
    "description": "{{appDescription}}",
    "applicationVersion": {
      "version": "1.0.0"
    },
  },
  "sap.ui": {
    "technology": "UI5",
    "deviceTypes": {
      "desktop": true,
      "tablet": true,
      "phone": true
    }
  },
  "sap.ui5": {
    "rootView": "singleFile.view.App",
    "dependencies": {
      "minUI5Version": "1.30",
      "libs": {
        "sap.m": {}
      }
    },
    "models": {
      "i18n": {
        "type": "sap.ui.model.resource.ResourceModel",
        "settings": {
          "bundleName": "singleFile.i18n.i18n"
        }
      }
    }
  }
}
```

App.view.xml

The `App.view.xml` file specifies how the page in the application will be laid out. We have one form container containing two form elements (`formElement`). The first `formElement` element contains the fields for loading 2D or 3D resources located remotely. We have specifed one input text field, and two buttons: one button for loading 2D images, and the other button for loading 3D models.

In the second `formElement`, we are using the `FileUploader` control to generate an input text field and a button to load 2D or 3D resources stored locally. We have specified the following file types as valid file types for loading using this `formElement`.

The labels for each of the fields are specified in the text attributes.

```
<mvc:View

            </Page>
        </App>
    </mvc:View>
```

App.controller.js

This file contains the logic for loading files into the Viewer application.

- The `handleEmptyUrl` function specifies what should occur if a user clicks on any of the buttons for loading, without having specified a URL to a resource first.
- The `loadModelIntoViewer` function specifies how the resource will be loaded into the Viewer application for viewing.
- The following event functions specify how the form elements should behave during certain events. The following list outlines what each of the functions do:
  - `onInit` - declares an empty structure when the controller is initialized. The empty structure is set as the model for the URLs.
  - `onPressLoadRemoteModel` - the logic for the button that loads 3D resources stored remotely.
  - `onPressLoadRemoteImage` - the logic for the button that loads 2D resources stored remotely.
  - `onChangeFileUploader` - the logic for the fields that load 2D or 3D resources stored locally.

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/ui/vk/ContentResource",
    "sap/m/MessageToast"
], function(Controller, JSONModel, ContentResource, MessageToast) {
    "use strict";
    var handleEmptyUrl = function(view) {
        var oBundle = view.getModel("i18n").getResourceBundle();
        var msg = oBundle.getText("missingUrl");
        MessageToast.show(msg);
    };
    var loadModelIntoViewer = function(viewer, remoteUrl, sourceType, localFile)
{
        //what is currently loaded in the view is destroyed
        viewer.destroyContentResources();
        var source = remoteUrl || localFile;
        if (source) {

            //content of viewer is replaced with new data
            var contentResource = new ContentResource({
                source: remoteUrl,
                sourceType: sourceType,
                sourceId: "abc"
            });
            //content: chosen path. content added to the view
            viewer.addContentResource(contentResource);
        }
    };
    return Controller.extend("singleFile.controller.App", {
        onInit: function() {
            var sourceData = {
                localFile: undefined,
                remoteUrl: undefined
            };
            var model = new JSONModel();
```

```
            model.setData(sourceData);
            this.getView().setModel(model, "source");
        },
        onPressLoadRemoteModel: function(event) {
            var view = this.getView();
            var sourceData = view.getModel("source").oData;
            var viewer = view.byId("viewer");
            if (sourceData.remoteUrl) {
                loadModelIntoViewer(viewer, sourceData.remoteUrl, "vds");
            } else {
                handleEmptyUrl(view);
            }
        },
        onPressLoadRemoteImage: function(event) {
            var view = this.getView();
            var sourceData = view.getModel("source").oData;
            var viewer = view.byId("viewer");
            if (sourceData.remoteUrl) {
                loadModelIntoViewer(viewer, sourceData.remoteUrl, "jpg");
            } else {
                handleEmptyUrl(view);
            }
        },
        onChangeFileUploader: function(event) {
            var view = this.getView();
            var viewer = view.byId("viewer");
            var localFile = event.getParameter("files")[0];
            //if user selects a local file
            if (localFile) {
                var fileName = localFile.name;
                var index = fileName.lastIndexOf(".");
                if (index >= 0 && index < fileName.length - 1) {
                    var sourceType = fileName.substr(index + 1);
                    loadModelIntoViewer(viewer, null, sourceType, localFile);
                }
            }
        }
    });
});
```

Testing the Application

To test that the application works, we will load a local 3D resource into the Viewer application.

Download the `boxTestModel.vds` file from the *Samples*. Click the *Browse...* button, navigate to the folder where the 3D resource is located, and load the model. Your screen should look like the following screenshot:

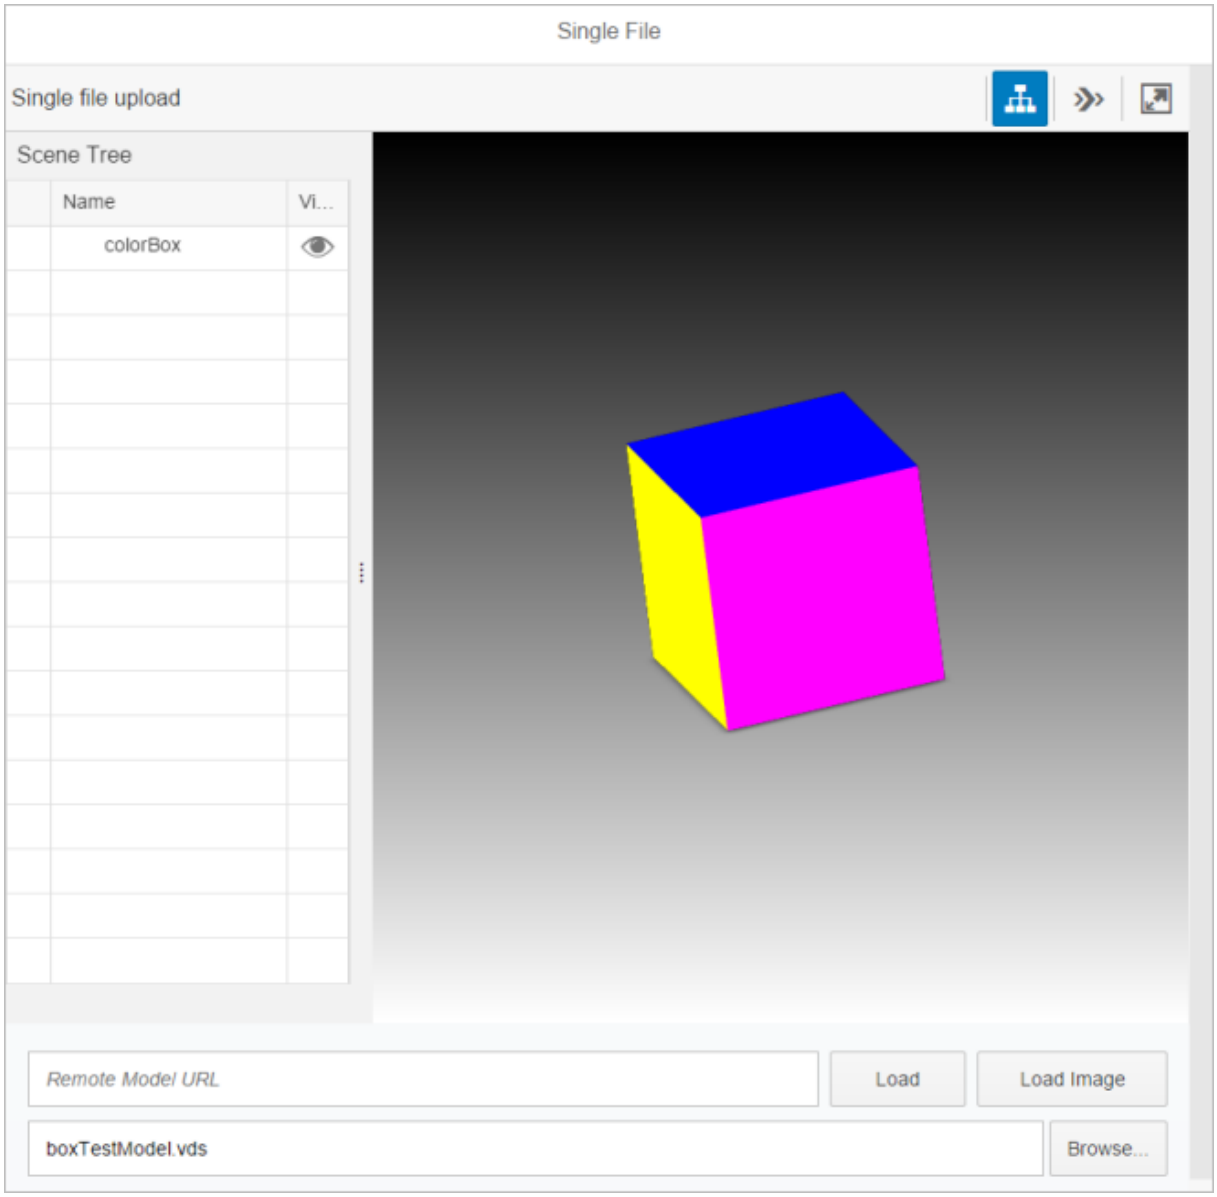

Figure 204: Viewer application loaded with a single VDS file

API Reference

- sap.ui.vk.Viewer
- sap.ui.vk.ContentResource

Step 2: 3D Viewer With Multiple File Loading

In this step, you will be creating a Viewer application that allows a user to load multiple 3D resources stored locally.

> ⚠ Caution
>
> The controls in the `sap.ui.vk` library are currently flagged as experimental. For more information, see Compatibility Rules [page 17].

The content in this tutorial step references Step 1: 3D Viewer With Single File Loading [page 609] for comparative purposes.

Preview

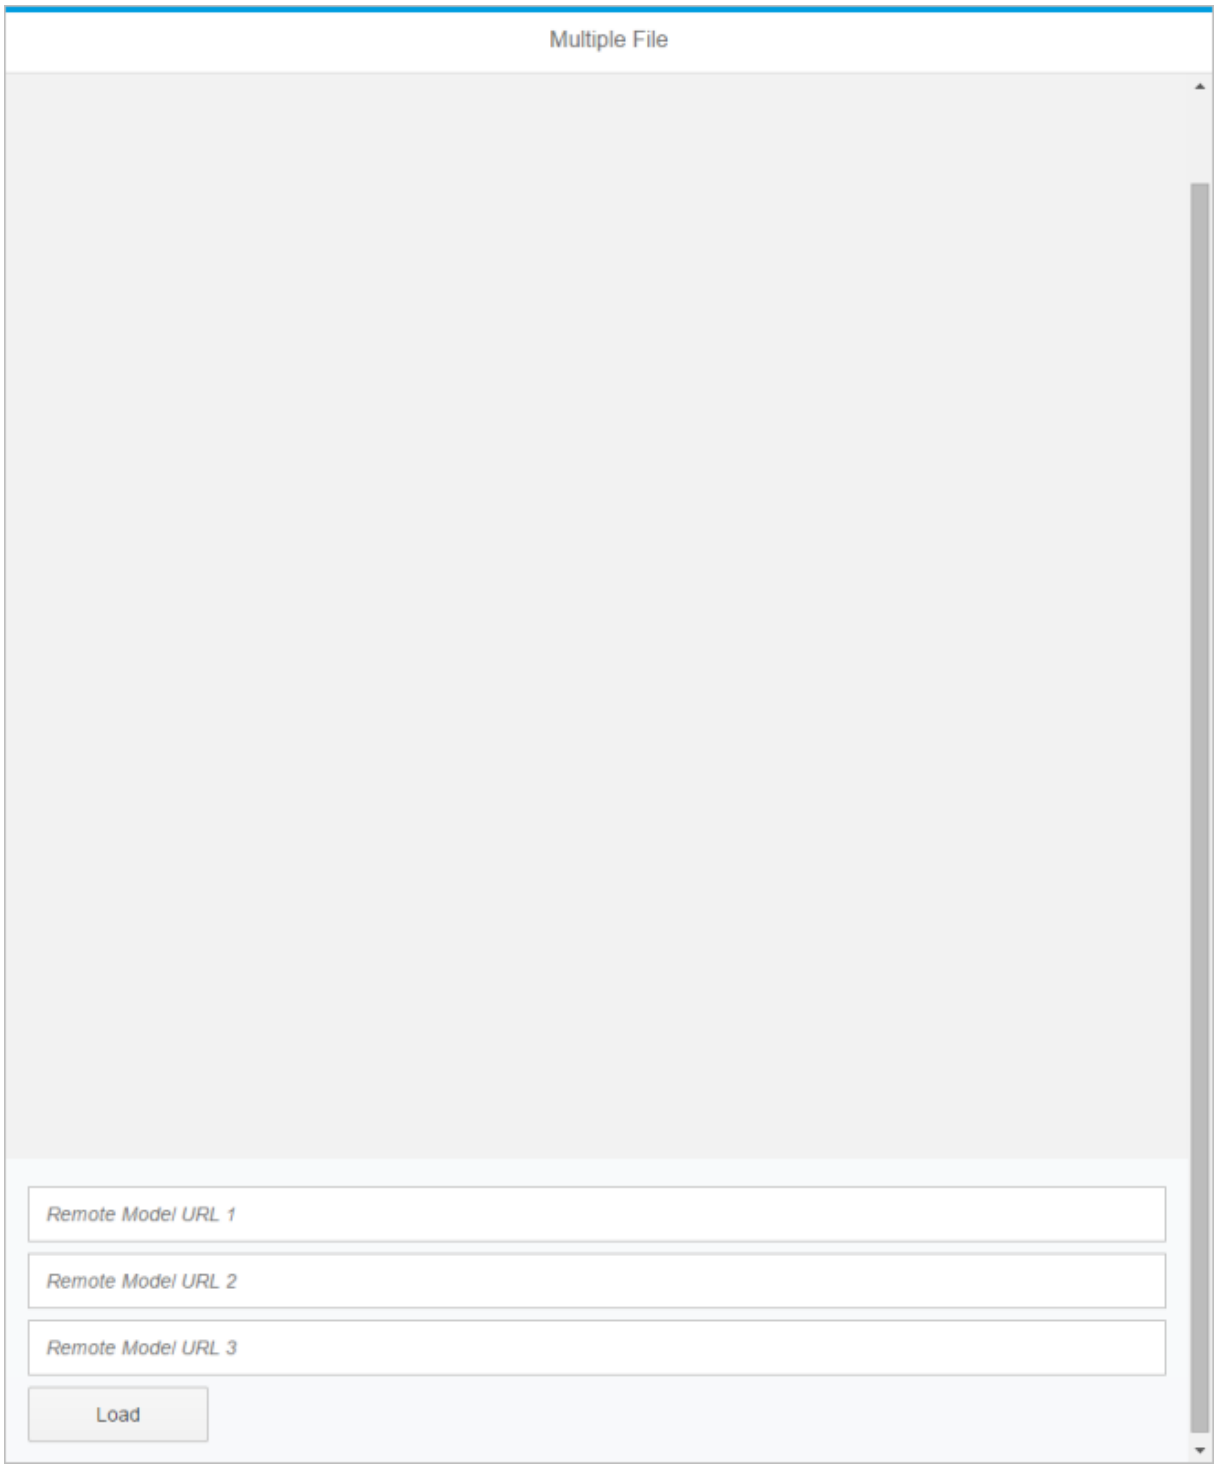

Figure 205: Viewer application with multiple file loading capability

Coding

You can view and download all files at 3D Viewer - Step 2 - Multiple File Loading .

index.html

Update the `index.html` file to reference the `multipleFiles` namespace, which will be the namespace we'll use for the sample application in this step.

```
<!DOCTYPE HTML>
<html>
    <head>
        <meta http-equiv="X-UA-Compatible" content="IE=edge">
        <meta http-equiv="Content-Type" content="text/html;charset=UTF-8"/>
        <script id="sap-ui-bootstrap"
            src="../../../../../../../../../resources/sap-ui-core.js"
            data-sap-ui-libs="sap.ui.vk, sap.m"
            data-sap-ui-theme="sap_belize"
            data-sap-ui-bindingSyntax="complex"
            data-sap-ui-resourceroots='{
                "multipleFiles": "./"
            }'>
        </script>
        <script>
        sap.ui.getCore().attachInit(function(){
            new sap.m.Shell({
                app: new sap.ui.core.ComponentContainer({
                    name : "multipleFiles"
                })
            }).placeAt("content");
        });
        </script>
    </head>
    <body id="content" class="sapUiBody">
    </body>
</html>
```

Component.js

Update the `Component.js` file to reference the namespace specified for this application.

```
sap.ui.define([
        "sap/ui/core/UIComponent"
], function (UIComponent) {
        "use strict";
        return UIComponent.extend("multipleFiles.Component", {
        metadata: {
            manifest: "json"
        },
        init: function () {
            // call the init function of the parent
            UIComponent.prototype.init.apply(this, arguments);
        }
    });
});
```

i18n.properties

In the `i18n.properties` file, we have labels for the toolbar, the page title, the three input fields, the *Load* button, and the error message that is displayed when the user attempts to load a model without specifying one to load.

```
# App Descriptor
appTitle=App title
appDescription=This is a description coming from the i18n as specified in
manifest.json

# Viewer Descriptor
```

```
viewerToolbarTitle=Upload multiple files

# Page Descriptor
pageTitle=Multiple File

# Form Descriptor
formRemoteURL1=Remote Model URL 1
formRemoteURL2=Remote Model URL 2
formRemoteURL3=Remote Model URL 3
buttonLoadModel=Load

# Message Toast
missingUrl=Please specify at least one URL
```

manifest.json

Update the `manifest.json` file so that it references the correct files.

```
{
    "_version": "1.8.0",
    "sap.app": {
        "id": "multipleFiles",
        "type": "application",
        "i18n": "i18n/i18n.properties",
        "title": "{{appTitle}}",
        "description": "{{appDescription}}",
        "applicationVersion": {
            "version": "1.0.0"
        },
    },
    "sap.ui": {
        "technology": "UI5",
        "deviceTypes": {
            "desktop": true,
            "tablet": true,
            "phone": true
        }
    },
    "sap.ui5": {
        "rootView": "multipleFiles.view.App",
        "dependencies": {
            "minUI5Version": "1.30",
            "libs": {
                "sap.m": {}
            }
        },
        "models": {
            "i18n": {
                "type": "sap.ui.model.resource.ResourceModel",
                "settings": {
                    "bundleName": "multipleFiles.i18n.i18n"
                }
            }
        }
    }
}
```

App.view.xml

This file specifies how the page in the application will be laid out. We only have one `formElement` in the form container, which contains the fields for loading 3D resources that are stored locally. In the element, we have specified three input text fields and one button for loading. The labels to use for each of the fields are specified in the text attributes.

```
<mvc:View
```

```
    controllerName="multipleFiles.controller.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"

                                         <layoutData>
                                             <l:GridData span="L2 M2 S2" />
                                         </layoutData>
                                     </Button>
                                 </f:fields>
                             </f:FormElement>
                         </f:formElements>
                     </f:FormContainer>
                 </f:formContainers>
             </f:Form>
         </Page>
     </App>
</mvc:View>
```

App.controller.js

Since we now have a different layout for the Viewer application compared to the sample Viewer application in Step 1: 3D Viewer With Single File Loading [page 609], we will need to change the logic for the application to accommodate for multiple file loading.

Add the `checkIfAllInputsEmpty` function to check whether the user has entered text into any of the input fields in the application. The `checkIfAllInputsEmpty` function returns the value `true` if the user hasn't entered any input at all, and the existing `handleEmptyUrl` function is called to display a message on the screen.

Update the `onInit` function so that we are specifying an empty data structure with three properties (`url1`, `url2`, and `url3`).

Replace the `loadModelIntoViewer` and `onPressLoadRemoteModel` functions with the following functions:

- `loadModelsIntoViewer` - loads the models into Viewer
- `onPressLoadRemoteModels` - handles the click event on the *Load* button

Remove the following functions:

- `onPressLoadRemoteImage` (since we are only loading 3D resources)
- `onChangeFileUploader` (since we are not using the FileUploader control for this application)

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/ui/vk/ContentResource",
    "sap/m/MessageToast"
], function (Controller, JSONModel, ContentResource, MessageToast) {
    "use strict";

    //throws a Message Toast alert on the screen
    //when the user tries to load a model but there's no url specified
    var handleEmptyUrl = function (view) {
        var oBundle = view.getModel("i18n").getResourceBundle();
        var msg = oBundle.getText("missingUrl");
        MessageToast.show(msg);
    };

    //checks if all URL input fields are empty or not
    var checkIfAllInputsEmpty = function (urls) {
        var allEmpty = true;
        for (var i = 0; i < urls.length; i++) {
            if (urls[i]) {
                allEmpty = false;
                break;
            }
        }
        return allEmpty;
    }

    //loads the models from the URLs into the viewer
    var loadModelsIntoViewer = function (viewer, urls, sourceType) {
        //clears all the models currently loaded in the viewer
        viewer.destroyContentResources();

        //iterates through all URLs
        //and loads all models into the viewer
        for (var i = 0; i < urls.length; i++) {
            if (urls[i]) {
                var contentResource = new ContentResource({
                    source: urls[i],
                    sourceType: sourceType,
```

```
                    sourceId: "abc"
                   name: urls[i].split("/")[2]
                });
                //add current model to the viewer
                viewer.addContentResource(contentResource);
            }
        }
    };
    return Controller.extend("multipleFiles.controller.App", {
        //when the controller is initialized,
        //we declare an empty structure and
        //we set this as model for the URLs
        onInit: function () {
            var sourceData = {
                url1: "",
                url2: "",
                url3: ""
            };
            var model = new JSONModel();
            model.setData(sourceData);
            this.getView().setModel(model, "source");
        },

        //onPressLoadRemoteModels handles the click event on the LOAD button
        onPressLoadRemoteModels: function (event) {
            var view = this.getView();
            //set the source model to a variable
            var sourceData = view.getModel("source").getData;

            //get the current viewer control
            var viewer = view.byId("viewer");

            //create the list of URLs from the input fields
            var urls = [sourceData.url1, sourceData.url2, sourceData.url3];

            //if all URL inputs are empty show an alert on the screen
            //if at least one URL is specified, then take the URL list
            //and load all existing ones into the viewer
            if (checkIfAllInputsEmpty(urls)) {
                handleEmptyUrl(view);
            } else {
                loadModelsIntoViewer(viewer, urls, "vds");
            }
        }
    });
});
```

Testing the Application

To test that the application works, we will load three 3D resources into the Viewer application.

Download the following VDS files from the *Samples* in the Demo Kit:

- `boxTestModel.vds`
- `coneTestModel.vds`
- `cylinderTestModel.vds`

Type in the file path of the VDS files into each of the input text fields, and click on the *Load* button to load the 3D models. Your screen should look like the following screenshot:

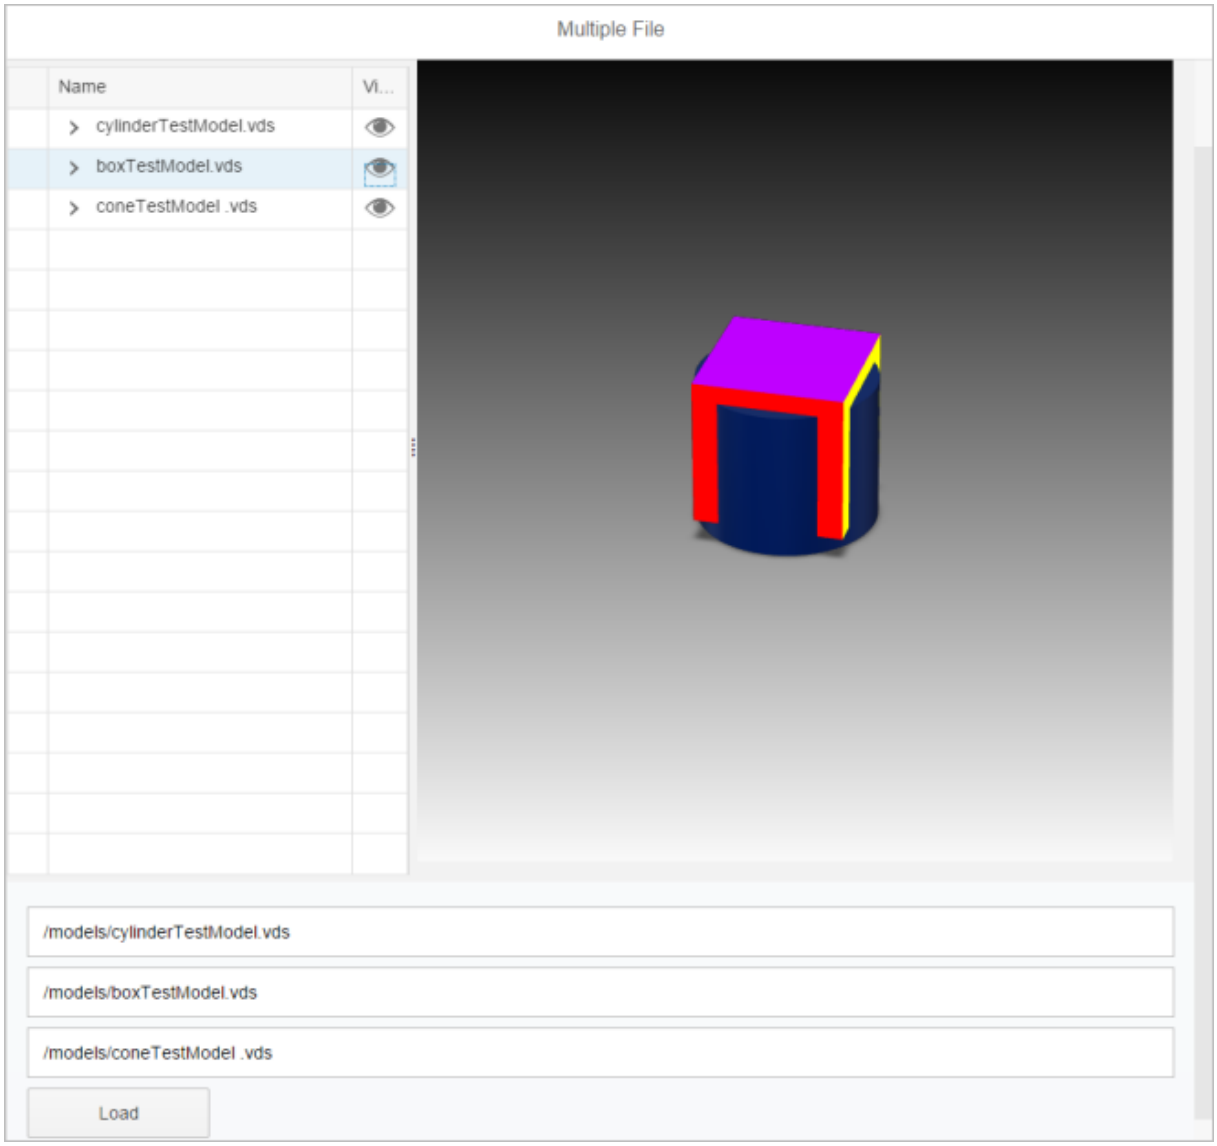

Figure 206: Viewer application loaded with three VDS files

API Reference

- sap.ui.vk.GraphicsCore

Step 3: 3D Viewer Using the Viewport Control

In this step, you will be creating a 3D Viewer application using the `sap.ui.vk.Viewport` control.

> ⚠ Caution
>
> The controls in the `sap.ui.vk` library are currently flagged as experimental. For more information, see Compatibility Rules [page 17].

In previous steps, we utilized the `sap.ui.vk.Viewer` composite control to create a Viewer application capable of loading a 2D or 3D resource. Now, we will create a Viewer application with a pre-loaded resource without using the composite `sap.ui.vk.Viewer` control. Instead, we will use the following controls and library in `sap.ui.vk`, which are what you'll need at a minimum to display a 3D model in your application.

- `Viewport` control
- `ContentResource` control
- `GraphicsCore` library

We will build on this sample application in later steps of the 3D Viewer tutorial by introducing the other non-composite `sap.ui.vk` controls to create more complex Viewer applications.

Preview

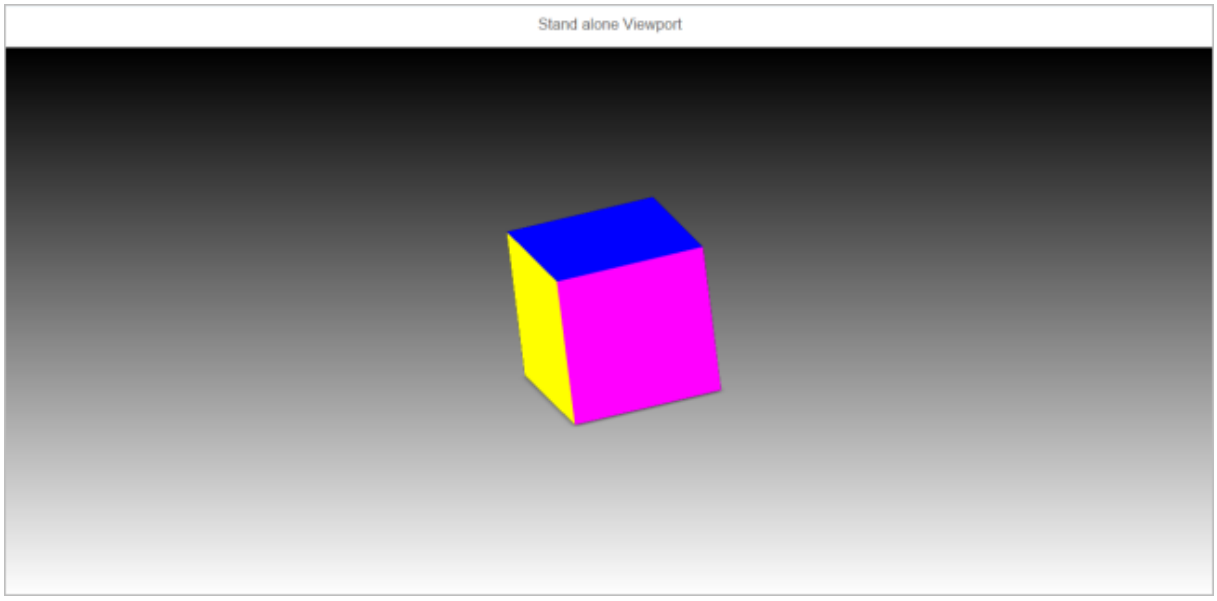

Figure 207: Viewer application that consists solely of a Viewport

Coding

You can view and download all files at 3D Viewer - Step 3 - Standalone Viewport.

index.html

Update the `index.html` file to reference the `standaloneViewport` namespace, which will be the namespace we'll use for the sample application in this step.

```
<!DOCTYPE HTML>
<html>
    <head>
        <meta http-equiv="X-UA-Compatible" content="IE=edge">
        <meta http-equiv="Content-Type" content="text/html;charset=UTF-8"/>
        <script id="sap-ui-bootstrap"
            src="../../../../../../../../../resources/sap-ui-core.js"
            data-sap-ui-libs="sap.ui.vk"
```

```
            data-sap-ui-theme="sap_belize"
            data-sap-ui-bindingSyntax="complex"
            data-sap-ui-resourceroots='{
                "standaloneViewport": "./"
            }'>
        </script>
        <script>
        sap.ui.getCore().attachInit(function(){
            new sap.m.Shell({
                app: new sap.ui.core.ComponentContainer({
                    name : "standaloneViewport"
                })
            }).placeAt("content");
        });
        </script>
    </head>
    <body id="content" class="sapUiBody">
    </body>
</html>
```

Component.js

Update the `Component.js` file to reference the namespace specified for this application.

```
sap.ui.define([
        "sap/ui/core/UIComponent"
], function (UIComponent) {
        "use strict";
        return UIComponent.extend("standaloneViewport.Component", {
        metadata: {
            manifest: "json"
        },
        init: function () {
            // call the init function of the parent
            UIComponent.prototype.init.apply(this, arguments);
        }
    });
});
```

i18n.properties

Because we are not creating any fields that a user can interact with, we only have one line of code which specifies what the label for the page title is.

```
# Page Descriptor
pageTitle=Standalone Viewport
```

manifest.json

Update the `manifest.json` file so that it references the correct files.

```
{
    "_version": "1.8.0",
    "sap.app": {
        "id": "standaloneViewport",
        "type": "application",
        "i18n": "i18n/i18n.properties",
        "title": "{{appTitle}}",
        "description": "{{appDescription}}",
        "applicationVersion": {
            "version": "1.0.0"
        }
    },
    "sap.ui": {
```

```
        "technology": "UI5",
        "deviceTypes": {
            "desktop": true,
            "tablet": true,
            "phone": true
        }
    },
    "sap.ui5": {
        "rootView": "standaloneViewport.view.App",
        "dependencies": {
            "minUI5Version": "1.30",
            "libs": {
                "sap.m": {}
            }
        },
        "models": {
            "i18n": {
                "type": "sap.ui.model.resource.ResourceModel",
                "settings": {
                    "bundleName": "standaloneViewport.i18n.i18n"
                }
            }
        }
    }
}
```

App.view.xml

Because the Viewport is the only item that we need to display on the application screen, we only need to have the `<vk:Viewport>` element added to this file. In the element's attributes, we specify the Viewport's width and height on the screen, and also give it an arbitrary identifier value.

```
<mvc:View
        controllerName="standaloneViewport.controller.App"
        xmlns="sap.m"
        xmlns:mvc="sap.ui.core.mvc"
        xmlns:vk="sap.ui.vk"
        xmlns:l="sap.ui.layout"
        xmlns:f="sap.ui.layout.form"
        xmlns:u="sap.ui.unified"
        displayBlock="true">
    <App id="standaloneViewport">
        <Page
            title="{i18n>pageTitle}">
            <vk:Viewport
                    id="viewport"
                    width="100%"
                    height="50%"/>
        </Page>
    </App>
</mvc:View>
```

App.controller.js

The logic in this `App.controller.js` file can be summarized as follows:

1. Create a Content Resource that stores a pre-specified model
2. Initiate a scene in our application in the following order:
    1. Create a Graphics Core instance
    2. Create a Viewport that is bound to the Graphics Core instance
    3. Load the Content Resource to the Graphics Core for rendering on the Viewport

```
sap.ui.define([
```

```
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/ui/vk/ContentResource",
], function (Controller, JSONModel, ContentResource) {
    "use strict";

    var contentResource = new sap.ui.vk.ContentResource({
        source: "/models/boxTestModel.vds",
        sourceType: "vds",
        id: "abc123"
    });

    return Controller.extend("standaloneViewport.controller.App",{
        onInit: function() {

            var mainScene;

            jQuery.sap.require("sap.ui.vk.GraphicsCore");
            var graphicsCore = new sap.ui.vk.GraphicsCore({},{
                antialias: true,
                alpha: true,
                premultipliedAlpha: false
            });

            var view = this.getView();
            var viewport = view.byId("viewport");

            viewport.setGraphicsCore(graphicsCore);
            graphicsCore.loadContentResourcesAsync([contentResource],
function(sourcesFailedToLoad){
                if (sourcesFailedToLoad){
                    jQuery.sap.log.error("Some of content resources cannot be
loaded.");
                } else {
                    var scene = graphicsCore.buildSceneTree([contentResource]);
                    if (scene){
                        mainScene = scene;
                        viewport.setScene(mainScene);
                    } else {
                        jQuery.sap.log.error("Failed to load viewport");
                    }
                }
            });
        }
    });
});
```

We'll now break the code down to look at each part in more detail.

Create a New Content Resource

Create a `contentResource` object that specifies the resource to load. In this case, we're pre-loading the `boxTestModel.vds` model into the application. This occurs before the scene in our Viewer application is initiated.

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/ui/vk/ContentResource",
], function (Controller, JSONModel, ContentResource) {
    "use strict";
    var contentResource = new sap.ui.vk.ContentResource({
        source: "/models/boxTestModel.vds",
        sourceType: "vds",
        id: "abc123"
```

Create a New Graphics Core Instance

Create a new Graphics Core instance. We're only specifying one input parameter, which is for the WebGL context attributes. We then get the current viewport, and attach it to the Graphics Core instance so the model we've loaded can be rendered.

```
return Controller.extend("standaloneViewport.controller.App",{
    onInit: function() {

    var mainScene;
        jQuery.sap.require("sap.ui.vk.GraphicsCore");
        var graphicsCore = new sap.ui.vk.GraphicsCore({},{
            antialias: true,
            alpha: true,
            premultipliedAlpha: false
        });
        var view = this.getView();
        var viewport = view.byId("viewport");

        viewport.setGraphicsCore(graphicsCore);
```

Load the Content Resource for Rendering

Now that we've associated the viewport with the Graphics Core, we can load our model to be displayed on the Viewport. In the following code block, we have specified some checks to make sure that the model loads correctly. If no resource is loaded, or if there is an error loading the resource, we throw the following error on the screen "Some of content resources cannot be loaded". Otherwise, we build a scene with the loaded resource, and then display this scene on the viewport. If the scene itself does not load into the Viewport, we throw an error saying the scene could not be built "Failed to build the scene."

```
graphicsCore.loadContentResourcesAsync([contentResource],
function(sourcesFailedToLoad){
    if (sourcesFailedToLoad){
        jQuery.sap.log.error("Some of content resources cannot be loaded.");
    } else {
        var scene = graphicsCore.buildSceneTree([contentResource]);
            if (scene){
                mainScene = scene;
                viewport.setScene(mainScene);
            } else {
                jQuery.sap.log.error("Failed to load viewport");
            }
    }
});
}
});
```

API Reference

- sap.ui.vk.Viewport

Related Information

Viewport [page 2480]

Step 4: Adding a Scene Tree

In this step, you will be adding an `sap.ui.vk.SceneTree` control to your 3D Viewer application.

> ⚠ Caution
>
> The controls in the `sap.ui.vk` library are currently flagged as experimental. For more information, see Compatibility Rules [page 17].

The following `sap.ui.vk` controls are introduced in this step:

- `SceneTree` control
- `ViewStateManager` control

We will use the `SceneTree` control to create a tree structure that displays the hierarchy of the nodes for the loaded model. We will then use the `ViewStateManager` control to link the Scene Tree with the model loaded into the Viewport, so that we can visually associate a selection in the scene with its corresponding node as displayed in the Scene Tree.

The content in this step builds on the code from Step 3: 3D Viewer Using the Viewport Control [page 624], and code changes performed in this step of the tutorial are done in relation to the files in Step 3: 3D Viewer Using the Viewport Control [page 624].

Preview

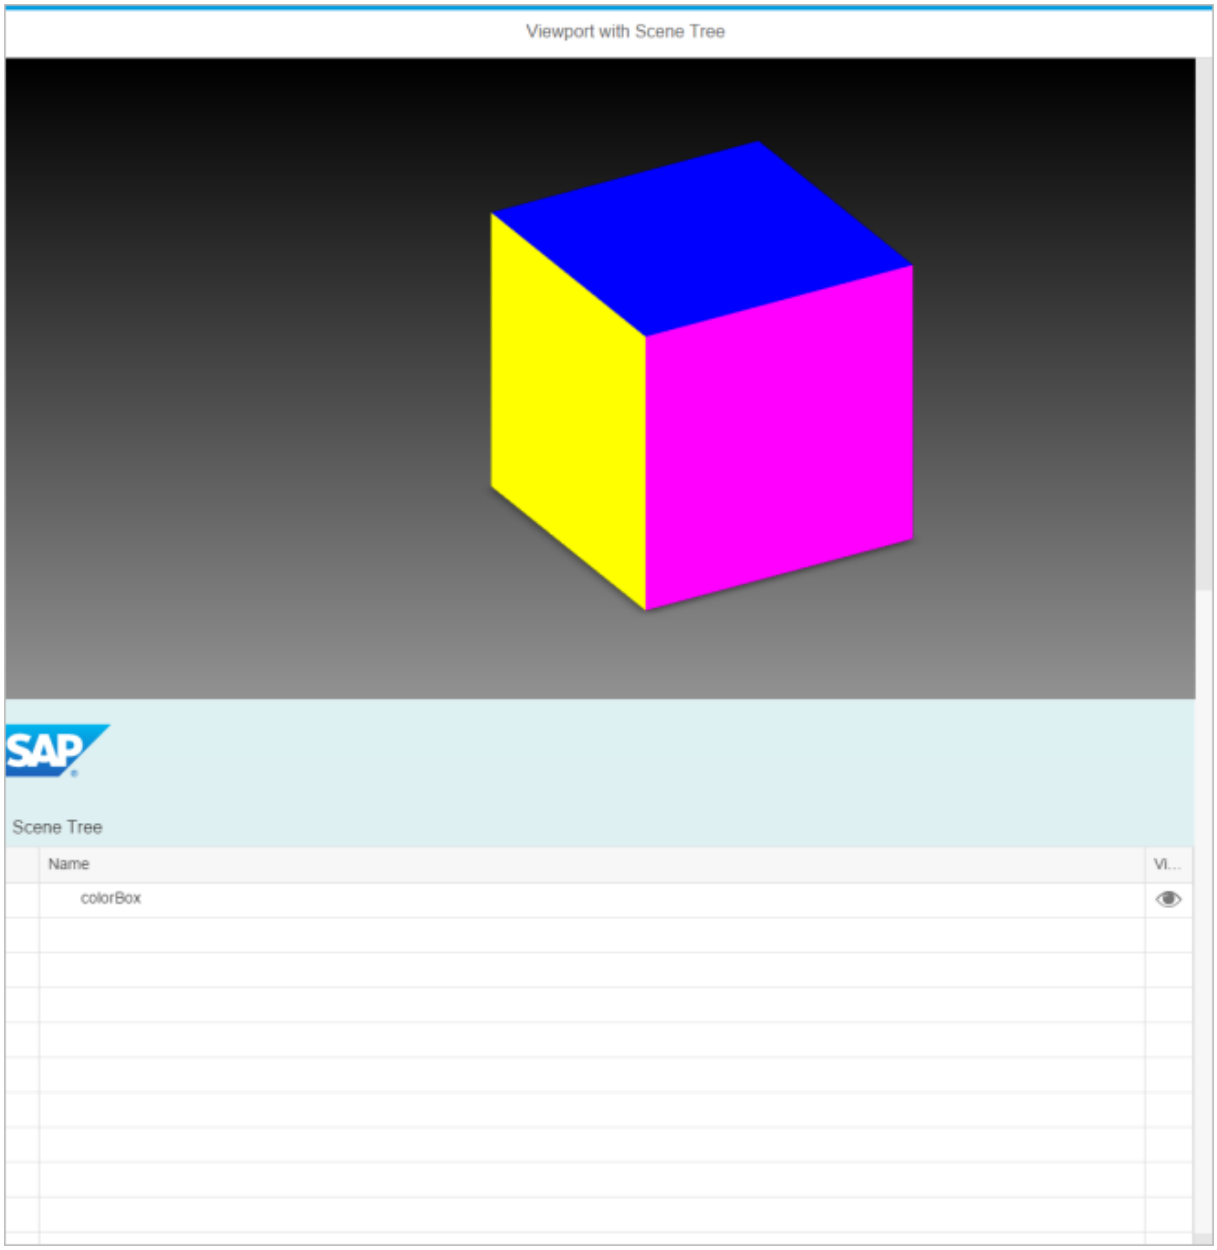

Figure 208: Viewer application with a Viewport and a Scene Tree

Coding

You can view and download all files at 3D Viewer - Step 4 - Viewport with Scene Tree.

index.html

Update the `index.html` file to reference the `viewportScenetree` namespace, which will be the namespace we'll use for the sample application in this step.

```
<!DOCTYPE HTML>
```

```
<html>
    <head>
        <meta http-equiv="X-UA-Compatible" content="IE=edge">
        <meta http-equiv="Content-Type" content="text/html;charset=UTF-8"/>
    <script id="sap-ui-bootstrap"
        src="../../../../../../../../../resources/sap-ui-core.js"
        data-sap-ui-libs="sap.ui.vk, sap.m"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-bindingSyntax="complex"
        data-sap-ui-resourceroots='{
            "viewportScenetree": "./"
        }'>
    </script>
    <script>
    sap.ui.getCore().attachInit(function(){
        new sap.m.Shell({
            app: new sap.ui.core.ComponentContainer({
                name : "viewportScenetree"
            })
        }).placeAt("content");
    });
    </script>
    </head>
    <body id="content" class="sapUiBody">
    </body>
</html>
```

Component.js

Update the `Component.js` file to reference the namespace specified for this application.

```
sap.ui.define([
    "sap/ui/core/UIComponent"
], function (UIComponent) {
    "use strict";
    return UIComponent.extend("viewportScenetree.Component", {
        metadata: {
            manifest: "json"
        },
        init: function () {
            // call the init function of the parent
            UIComponent.prototype.init.apply(this, arguments);
        }
    });
});
```

i18n.properties

Update the page title to say "Viewport with Scene Tree".

```
# Page Descriptor
pageTitle=Viewport with Scene Tree
```

manifest.json

Update the `manifest.json` file so that it references the correct files.

```
{
    "_version": "1.8.0",
    "sap.app": {
        "id": "viewportScenetree",
        "type": "application",
        "i18n": "i18n/i18n.properties",
        "title": "{{appTitle}}",
```

```
        "description": "{{appDescription}}",
        "applicationVersion": {
            "version": "1.0.0"
        }
    },
    "sap.ui": {
        "technology": "UI5",
        "deviceTypes": {
            "desktop": true,
            "tablet": true,
            "phone": true
        }
    },
    "sap.ui5": {
        "rootView": "viewportScenetree.view.App",
        "dependencies": {
            "minUI5Version": "1.30",
            "libs": {
                "sap.m": {}
            }
        },
        "models": {
            "i18n": {
                "type": "sap.ui.model.resource.ResourceModel",
                "settings": {
                    "bundleName": "viewportScenetree.i18n.i18n"
                }
            }
        }
    }
}
```

App.view.xml

To display the Scene Tree in your application, add the `<vk:SceneTree>` element. In the element's attribute's, specify the Scene Tree control's width and height on the screen, and give it an arbitrary identifier value.

```
<mvc:View
        controllerName="viewportScenetree.controller.App"
        xmlns="sap.m"
        xmlns:mvc="sap.ui.core.mvc"
        xmlns:vk="sap.ui.vk"
        xmlns:l="sap.ui.layout"
        xmlns:f="sap.ui.layout.form"
        xmlns:u="sap.ui.unified"
        displayBlock="true">
    <App id="viewportScenetree">
        <Page
                title="{i18n>pageTitle}">
            <vk:Viewport
                    id="viewport"
                    width="100%"
                    height="25%"/>
            <vk:SceneTree
                    id="scenetree"
                    width="100%"
                    height="25%"/>
        </Page>
    </App>
</mvc:View>
```

App.controller.js

For the most part, the code in the `App.controller.js` file will be the same as the content of the `App.controller.js` file for the application in Step 3: 3D Viewer Using the Viewport Control [page 624]. The

highlighted sections in the following code block indicate the additions and changes made in the code to incorporate a Scene Tree in the 3D Viewer application.

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/ui/vk/ContentResource",
], function (Controller, JSONModel, ContentResource) {
    "use strict";
    var contentResource = new sap.ui.vk.ContentResource({
        source: "/models/boxTestModel.vds",
        sourceType: "vds",
        id: "abc123"
    });
    return Controller.extend("viewportScenetree.controller.App",{
        onInit: function() {
            var mainScene;
            jQuery.sap.require("sap.ui.vk.GraphicsCore");
            var graphicsCore = new sap.ui.vk.GraphicsCore({},{
                antialias: true,
                alpha: true,
                premultipliedAlpha: false
            });
            var view = this.getView();
            var viewport = view.byId("viewport");
            var sceneTree = view.byId("scenetree");
            viewport.setGraphicsCore(graphicsCore);
            graphicsCore.loadContentResourcesAsync([contentResource],
function(sourcesFailedToLoad){
                if (sourcesFailedToLoad){
                    jQuery.sap.log.error("Some of content resources cannot be
loaded.");
                } else {
                    var scene = graphicsCore.buildSceneTree([contentResource]);
                    if (scene){
                        mainScene = scene;
                        viewport.setScene(mainScene);
                        var viewStateManager =
graphicsCore.createViewStateManager(mainScene.getDefaultNodeHierarchy());
                        viewport.setViewStateManager(viewStateManager);
                        sceneTree.setScene(mainScene, viewStateManager);
                    } else {
                        jQuery.sap.log.error("Failed to build the scene tree.");
                    }
                }
            });
        }
    });
});
```

Let us look at the changes in more detail.

The following code line adds a new Scene Tree object.

```
var sceneTree = view.byId("scenetree");
```

We create a new object called `viewStateManager` that gets the node hierarchy of the resource that's loaded into the scene. Then, we associate the created `viewStateManager` object with our viewport. We also associate the nodes in the `viewStateManager` object, as well as the resource loaded into the main scene with the Scene Tree.

```
var viewStateManager =
graphicsCore.createViewStateManager(mainScene.getDefaultNodeHierarchy());
viewport.setViewStateManager(viewStateManager);
```

```
sceneTree.setScene(mainScene, viewStateManager);
```

Finally, we changed the message for the condition that determines whether the viewport and the scene tree loaded successfully or not.

```
jQuery.sap.log.error("Failed to build the scene tree.");
```

API Reference

- sap.ui.vk.SceneTree

Related Information

Scene Tree [page 2470]

Step 5: Adding Step Navigation

In this step, you will be adding the `sap.ui.vk.StepNavigation` control to a 3D Viewer application.

> ⚠ Caution
>
> The controls in the `sap.ui.vk` library are currently flagged as experimental. For more information, see Compatibility Rules [page 17].

Sometimes, you may encounter a 3D model that has a sequence of animations associated with it. The `StepNavigation` control allows you to display the steps in the animation sequence, navigate to the individual steps in the animation sequence, and play the animation in a single step or in all of the steps.

The content in this step builds on the code from Step 4: Adding a Scene Tree [page 630], and code changes performed in this step of the tutorial are done in relation to the files in Step 4: Adding a Scene Tree [page 630].

Preview

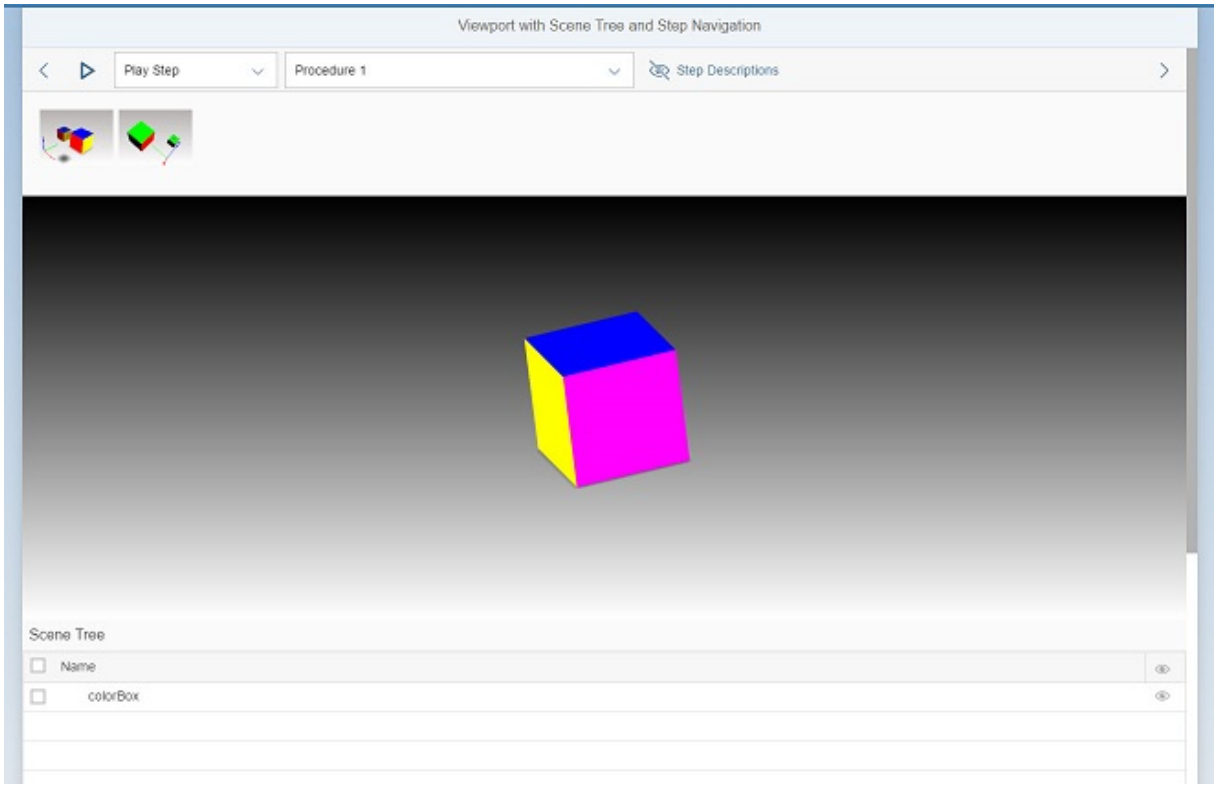

Figure 209: Viewer application with a Step Navigation, Viewport, and Scene Tree

Coding

You can view and download all files at 3D Viewer - Step 5 - Viewport with Scene Tree and Step Navigation.

index.html

Update the `index.html` file to reference the `viewportScenetreeStepnav` namespace, which will be the namespace we'll use for the sample application in this step.

```
<!DOCTYPE HTML>
<html>
    <head>
        <meta http-equiv="X-UA-Compatible" content="IE=edge">
        <meta http-equiv="Content-Type" content="text/html;charset=UTF-8"/>
    <script id="sap-ui-bootstrap"
        src="../../../../../../../../../resources/sap-ui-core.js"
        data-sap-ui-libs="sap.ui.vk, sap.m, sap.ui.core"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-bindingSyntax="complex"
        data-sap-ui-resourceroots='{
            "viewportScenetreeStepnav": "./"
        }'>
    </script>
    <script>
    sap.ui.getCore().attachInit(function(){
        new sap.m.Shell({
            app: new sap.ui.core.ComponentContainer({
                name : "viewportScenetreeStepnav"
```

```
            })
        }).placeAt("content");
    });
    </script>
    </head>
    <body id="content" class="sapUiBody">
    </body>
</html>
```

Component.js

Update the `Component.js` file to reference the namespace specified for this application.

```
sap.ui.define([
    "sap/ui/core/UIComponent"
], function (UIComponent) {
    "use strict";
    return UIComponent.extend("viewportScenetreeStepnav.Component", {
        metadata: {
            manifest: "json"
        },
        init: function () {
            // call the init function of the parent
            UIComponent.prototype.init.apply(this, arguments);
        }
    });
});
```

i18n.properties

Because we are not creating any fields that a user can interact with, we only have one line of code which specifies what the label for the page title is.

```
# Page Descriptor
pageTitle=Viewport with Scene Tree and Step Navigation
```

manifest.json

Update the `manifest.json` file so that it references the correct files.

```
{
    "_version": "1.8.0",
    "sap.app": {
        "id": "viewportScenetreeStepnav",
        "type": "application",
        "i18n": "i18n/i18n.properties",
        "title": "{{appTitle}}",
        "description": "{{appDescription}}",
        "applicationVersion": {
            "version": "1.0.0"
        }
    },
    "sap.ui": {
        "technology": "UI5",
        "deviceTypes": {
            "desktop": true,
            "tablet": true,
            "phone": true
        }
    },
    "sap.ui5": {
        "rootView": "viewportScenetreeStepnav.view.App",
        "dependencies": {
            "minUI5Version": "1.30",
```

```
            "libs": {
                "sap.m": {}
            }
        },
        "models": {
            "i18n": {
                "type": "sap.ui.model.resource.ResourceModel",
                "settings": {
                    "bundleName": "viewportScenetreeStepnav.i18n.i18n"
                }
            }
        }
    }
}<vk:StepNavigation>
```

App.view.xml

In this file, we have added a `<vk:StepNavigation>` element to this file. We have specified the width and height of the `StepNavigation` control on the screen.

```
<mvc:View
        controllerName="viewportScenetreeStepnav.controller.App"
        xmlns="sap.m"
        xmlns:mvc="sap.ui.core.mvc"
        xmlns:vk="sap.ui.vk"
        xmlns:l="sap.ui.layout"
        xmlns:f="sap.ui.layout.form"
        xmlns:u="sap.ui.unified"
        displayBlock="true">
    <App id="viewportScenetreeStepnav">
        <Page
                title="{i18n>pageTitle}">
                <vk:StepNavigation
                id="StepNavigation"
                width="100%"
                    height="17.5%"/>
            <vk:Viewport
                    id="viewport"
                    width="100%"
                    height="50%"/>
            <vk:SceneTree
                    id="scenetree"
                    width="100%"
                    height="50%"/>
        </Page>
    </App>
</mvc:View>
```

App.controller.js

The highlighted sections in the following code block indicate the additions and changes made in the code to incorporate step navigation in the 3D Viewer application.

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/ui/vk/ContentResource",
], function (Controller, JSONModel, ContentResource) {
    "use strict";
    var contentResource = new sap.ui.vk.ContentResource({
        source: "/models/boxTestModel.vds",
        sourceType: "vds",
        id: "abc123"
    });
    return Controller.extend("viewportScenetreeStepnav.controller.App",{
```

```
        onInit: function() {
            var mainScene;
            jQuery.sap.require("sap.ui.vk.GraphicsCore");
            var graphicsCore = new sap.ui.vk.GraphicsCore({},{
                antialias: true,
                alpha: true,
                premultipliedAlpha: false
            });
            var view = this.getView();
            var viewport = view.byId("viewport");
            var sceneTree = view.byId("scenetree");
            var stepNavigation = view.byId ("StepNavigation");
            viewport.setGraphicsCore(graphicsCore);
            graphicsCore.loadContentResourcesAsync([contentResource],
function(sourcesFailedToLoad){
                if (sourcesFailedToLoad){
                    jQuery.sap.log.error("Some of content resources cannot be
loaded.");
                } else {
                    var scene = graphicsCore.buildSceneTree([contentResource]);
                    if (scene){
                        mainScene = scene;
                        viewport.setScene(mainScene);
                        var viewStateManager =
graphicsCore.createViewStateManager(mainScene.getDefaultNodeHierarchy());
                        viewport.setViewStateManager(viewStateManager);
                        sceneTree.setScene(mainScene, viewStateManager);
                        stepNavigation.setScene(mainScene);
                    } else {
                        jQuery.sap.log.error("Failed to build the viewport, the
scene tree, and the step navigation.");
                    }
                }
            });
        }
    });
});
```

Let us look at the changes in more detail.

The following line of code adds a new Step Navigation object.

```
var stepNavigation = view.byId ("StepNavigation");
```

We then associate the scene with the Step Navigation object, so that the animation sequences in the model are displayed in the `StepNavigation` control.

```
stepNavigation.setScene(mainScene);
```

Finally, we changed the message for the condition that determines whether the Viewport, the Scene Tree, and the Step Navigation controls loaded successfully or not:

```
jQuery.sap.log.error("Failed to build the Viewport, the Scene Tree, and the Step
Navigation.");
```

Step Navigation [page 2474]

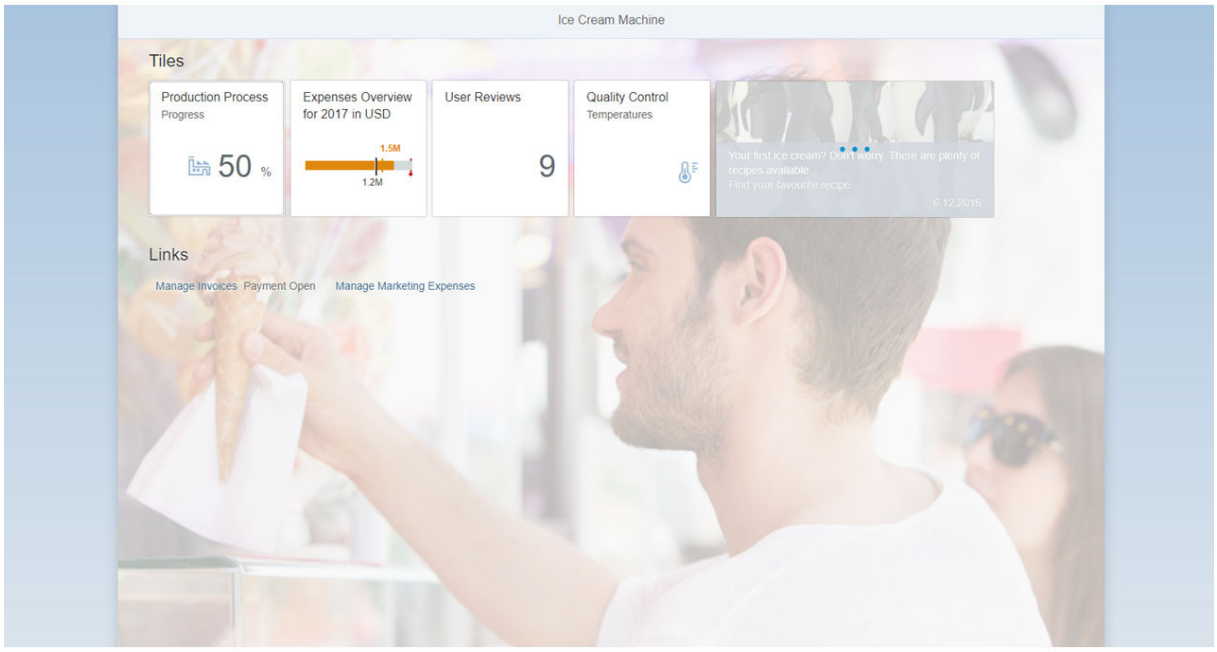
Ice Cream Machine

In this tutorial, we will show you how to use SAPUI5 controls like Generic Tiles, Micro Charts, and Process Flow.

Welcome to our **Ice Cream Machine** tutorial.

To get all of the important information about the production process at a glance, we will create a new start page. We will use the `GenericTile` control in different scenarios, the `NumericContent`, and several micro charts. The `ProcessFlow` will be used in a further view to display detailed data in the production process. We will create micro charts that show more specific information as in the `ProcessFlow`. In another view, the `ChartContainer` will be used to display the test results of the newly built ice cream machine. Finally, we will create an additional view with a `Timeline` control that will display our customer reviews.

Preview



Step 1: Initial Application

In the first step, we will explain how to get started with a development environment.

Choose your development environment

In this tutorial, you don't have to worry about creating any test data. Everything is already included in the initial app and you can reference the data in every step. You can view and download the samples for all steps in the Demo Kit at Ice Cream Machine.

> **i** Note
>
> Please keep in mind that we will not explain every single step of SAPUI5 application development, as we are focusing on selected controls. We will not cover topics like data binding, navigation, or the MVC pattern. For more information about these topics, see Essentials [page 691].

Creating an app

You can do this tutorial with SAP Web IDE (from SAPUI5 version 1.50) or with your own development environment. Just download the initial version of the final app from the sample here, extract the archive, and start coding.

For more information, check the following sections of the tutorials overview page (see Get Started: Setup, Tutorials, and Demo Apps [page 38]):

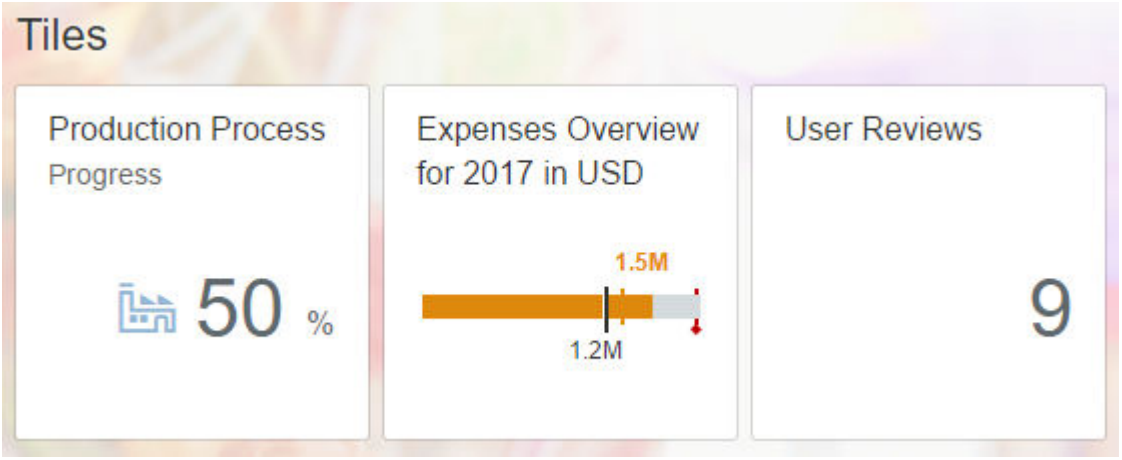
- Downloading Code for a Tutorial Step [page 40]
- Adapting Code to Your Development Environment [page 40]
- App Development Using SAP Web IDE [page 44]

Step 2: KPI Tile and Chart Tile on the Start Page

In this step, we will create our start page with the KPI Tile (`GenericTile` with `NumericContent`) and Chart Tile (`GenericTile` with `MicroChart`).

Preview

When you have completed this step, your start page will include the following tiles:



GenericTile with NumericContent

Let's start by creating the first `GenericTile` that shows the progress of the production process as percentage data (compared to all production steps). By selecting the **Production Process** tile, the user can navigate to another view to see the complete production process. We will implement this navigation in step 5.

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 2 - KPI Tile and Chart Tile in Start Page.

Startpage.view.xml

```
<mvc:View
    controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
02.controller.Startpage"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns="sap.m"
    xmlns:layout="sap.ui.layout">
    <Page title="{i18n>title}">
        <layout:VerticalLayout class="sapUiResponsiveMargin">
            <Title
                titleStyle="H2"
                text="{i18n>startpageTilesGroupTitle}"
                class="sapUiTinyMarginBegin" />
            <layout:HorizontalLayout allowWrapping="true">
                <GenericTile
                    class="sapUiTinyMarginBegin sapUiTinyMarginTop"
```

```
                    header="{i18n>startpagePFTileTitle}"
                    subheader="{i18n>startpagePFTileSubTitle}">
                    <tileContent>
                        <TileContent>
                            <content>
                                <NumericContent
                                    scale="%"
                                    value="{
                                        path: 'process>/Nodes',
                                        formatter: '.getProgress'
                                    }"
                                    icon="sap-icon://factory" />
                            </content>
                        </TileContent>
                    </tileContent>
                </GenericTile>
            </layout:HorizontalLayout>
        </layout:VerticalLayout>
    </Page>
</mvc:View>
```

First, we are going to add a `GenericTile` with the *header* and *subheader* properties in order to display the header and subheader . In the `TileContent` aggregation, the `TileContent` is added with a `NumericContent`. This lets you display a scale or unit with the *scale* property. The *value* property of the `NumericContent` displays the percentage value of the production progress by using a custom formatter. In our case, it is *.getProgress*. You can use any icon from the SAPUI5 icon poolas the *icon* property.

We will create another `GenericTile` with `NumericContent` in a similar way, which will navigate to another view. You can see customer reviews there. The number of reviews is displayed in this `GenericTile`. Navigation to the reviews view is implemented in step 5.

Startpage.view.xml

```
mvc:View
     controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
02.controller.Startpage"
     xmlns:mvc="sap.ui.core.mvc"
     xmlns="sap.m"
     xmlns:layout="sap.ui.layout">
     <Page title="{i18n>title}">
         <layout:VerticalLayout class="sapUiResponsiveMargin">
             <Title
                 titleStyle="H2"
                 text="{i18n>startpageTilesGroupTitle}"
                 class="sapUiTinyMarginBegin" />
             <layout:HorizontalLayout allowWrapping="true">
                ...
                <GenericTile
                     class="sapUiTinyMarginBegin sapUiTinyMarginTop"
                     header="{i18n>startpageUserReviewsTileTitle}">
                     <tileContent>
                         <TileContent>
                             <content>
                                 <NumericContent
                                     value="{
                                         path: 'reviews>/UserReviews',
                                         formatter: '.getEntityCount'
                                     }"
                                         indicator="None"
                                         valueColor="Neutral" />
                             </content>
                         </TileContent>
                     </tileContent>
                 </GenericTile>
```

```
            </layout:HorizontalLayout>
        </layout:VerticalLayout>
    </Page>
</mvc:View>
```

In the `NumericContent`, we only want to display the number of user reviews. Since we don't want to show indicators, we set the *indicator* property to **None**. We are choosing **Neutral** as a value for the *valueColor* property to display a neutral semantic color.

Startpage.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller"
], function(Controller) {
    "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
02.controller.Startpage", {
        ...
        getProgress: function(aNodes) {
                    if (!aNodes || aNodes.length === 0) {
                       return 0;
                    }
                    var iSum = 0;
                    for (var i = 0; i < aNodes.length; i++) {
                        iSum += aNodes[i].state === "Positive";
                    }
                    var fPercent = (iSum / aNodes.length) * 100;
                    return fPercent.toFixed(0);
                },
                getEntityCount: function(entities) {
                    return entities && entities.length || 0;
                }
    });
});
```

The *getProgress* function is the formatter function that belongs to the value binding of the `NumericContent` in the first `GenericTile`. It is used to return the ratio of positive process steps as compared to the complete number of process steps.

To get the number of user reviews in another `GenericTile`, we will add a new formatter called *.getEntityCount*. This formatter returns the number of entities found in the **reviews** JSON model.

GenericTile with BulletMicroChart

In the second tile on the start page, you can find an overview of the project expenses. We will use the `BulletMicroChart` control for this overview.

Startpage.view.xml

```
mvc:View
    controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
02.controller.Startpage"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns="sap.m"
    xmlns:layout="sap.ui.layout"
    xmlns:microchart="sap.suite.ui.microchart">
    <Page title="{i18n>title}">
        <layout:VerticalLayout class="sapUiResponsiveMargin">
```

```
            <Title
                titleStyle="H2"
                text="{i18n>startpageTilesGroupTitle}"
                class="sapUiTinyMarginBegin" />
            <layout:HorizontalLayout allowWrapping="true">
                                ...
               <GenericTile
                     class="sapUiTinyMarginBegin sapUiTinyMarginTop"
                     header="{
                         parts: [
                             'i18n>startpageCCTileTitle',
                             'business>/year',
                             'business>/currency'
                         ],
                         formatter: '.formatMessage'
                     }">
                     <tileContent>
                         <TileContent>
                             <content>
                                 <microchart:BulletMicroChart
                                     size="Responsive"
                                     targetValue="{business>/plannedExpenses}"
                                     targetValueLabel="{
                                        path: 'business>/plannedExpenses',
                                        formatter: '.formatNumber'
                                    }"
                                     actualValueLabel="{
                                        path: 'business>/expenses',
                                        formatter: '.formatNumber'
                                    }"
                                     minValue="0">
                                     <microchart:actual>
                                         <microchart:BulletMicroChartData
                                             value="{business>/expenses}"
                                             color="Critical" />
                                     </microchart:actual>
                                     <microchart:thresholds>
                                         <microchart:BulletMicroChartData
                                             value="{business>/expensesCritical}"
                                             color="Critical" />
                                         <microchart:BulletMicroChartData
                                             value="{business>/budget}"
                                             color="Error" />
                                     </microchart:thresholds>
                                 </microchart:BulletMicroChart>
                             </content>
                         </TileContent>
                     </tileContent>
                 </GenericTile>
            </layout:HorizontalLayout>
        </VBox>
    </Page>
</mvc:View>
```

We are adding a new `GenericTile`. Here, we are setting only the *header* property of the tile because we don't need a subheader. We want to display only the Expenses overview. The `BulletMicroChart` is in the *TileContent*. Do not forget to add a namespace for the `sap.suite.ui.microchart` library in the **.view.xml*.

We want to show our business data in the `BulletMicroChart`. To do so, we are adding the `BulletMicroChartData` element to the **actual** aggregation of the chart control. This data element has two properties:

1. The *value* property that is bound to a property in the data model
2. The *color* property that is set to **Critical** to show when the expenses are about to exceed the limit. This property shows the amount of money already spent on this project.

Similarly, we can add **thresholds** to the chart to show when our expenses become **critical** but still manageable. For expenses that are too high for the company, the **Error** color applies. This time, the *value* properties are directly bound to the properties in the data model. No formatting is needed as the values are used only by the chart and are not displayed directly.

Finally, we will add a *targetValue* to our chart to display an indicator that shows the planned spending.

Startpage.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/core/format/NumberFormat",
    "sap/base/strings/formatMessage"
], function(Controller, NumberFormat) {
    "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
02.controller.Startpage", {
        ...
        formatNumber: function(value) {
            var oFloatFormatter = NumberFormat.getFloatInstance({
                style: "short",
                decimals: 1
            });
            return oFloatFormatter.format(value);
        }
    });
});
```

Since the production of our ice cream has already cost us a lot of money and the monetary values are very high, we need to provide custom data labels in order to have a neat chart design. The custom data labels can be added via the *actualValueLabel* and *targetValueLabel* properties that are set on the `BulletMicroChart`. In both instances, we use data binding with a custom formatter function from the *Startpage.controller.js* file to format the values using a standard SAPUI5 number formatter.

Step 3: Launch Tile and Slide Tile

In this step, we will create a new Launch Tile (`GenericTile` with `ImageContent`) and a `SlideTile`.

Preview

Initializing the models

To configure the next `GenericTiles`, you need to create models that contain news data. You can find the source code of the model data in */model/data/News.json*.

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 3 - Launch Tile and Slide Tile.

Startpage.controller.js

```
sap.ui.define([
       "sap/ui/core/mvc/Controller",
"sap/ui/model/json/JSONModel",
       "sap/ui/core/format/NumberFormat",
       "sap/base/strings/formatMessage"
], function(jQuery, Controller, JSONModel, NumberFormat) {
       "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
03.controller.Startpage", {
     onInit: function() {
                var sDataPath = sap.ui.require.toUrl("sap/suite/ui/commons/
demokit/tutorial/icecream/03/model/data") + "/News.json";
                var oModel = new JSONModel(sDataPath);
                this.getView().setModel(oModel, "news");
                }
                ...
    });
});
```

You instantiate the models in the *onInit* hook function. They are then available when needed. If you choose a different resource root in your *index.html* file, keep in mind that you have to adapt the module path to the **.json* files whenever you load the file into a controller.

GenericTile with ImageContent

With the *ImageContent* control, you can create the second tile that contains only one image. With that tile, you can also navigate to another view (we will explain this implementation later).

Startpage.view.xml

```
<mvc:View
    controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
03.controller.Startpage"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns="sap.m"
    xmlns:layout="sap.ui.layout"
    xmlns:microchart="sap.suite.ui.microchart">
    <Page title="{i18n>title}">
        <layout:VerticalLayout class="sapUiResponsiveMargin">
            <Title
                titleStyle="H2"
                text="{i18n>startpageTilesGroupTitle}"
                class="sapUiTinyMarginBegin" />
            <layout:HorizontalLayout allowWrapping="true">
                ...
            <GenericTile
                    class="sapUiTinyMarginBegin sapUiTinyMarginTop"
                    header="{i18n>startpageTestResultsTileTitle}"
                    subheader="{i18n>startpageTestResultsTileSubTitle}">
```

```
                    <tileContent>
                        <TileContent>
                            <content>
                                <ImageContent src="sap-icon://temperature" />
                            </content>
                        </TileContent>
                    </tileContent>
                </GenericTile>

            </layout:HorizontalLayout>
        </layout:VerticalLayout>
    </Page>
</mvc:View>
```

Here, the `TileContent` has only one *ImageContent* with an icon set in the *src* property. If you like, you can choose another icon or image.

SlideTile with Two GenericTiles

With the `SlideTile`, we want to display news about the ice cream machine as well as the user reviews.

Startpage.view.xml

```
<mvc:View
    controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
03.controller.Startpage"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns="sap.m"
    xmlns:layout="sap.ui.layout"
    xmlns:microchart="sap.suite.ui.microchart">
    <Page title="{i18n>title}">
        <layout:VerticalLayout class="sapUiResponsiveMargin">
            <Title
                titleStyle="H2"
                text="{i18n>startpageTilesGroupTitle}"
                class="sapUiTinyMarginBegin" />
            <layout:HorizontalLayout allowWrapping="true">
                ..
         <SlideTile
                    class="sapUiTinyMarginBegin sapUiTinyMarginTop"
                    tiles="{news>/News}">
                    <GenericTile
                        backgroundImage="{news>image}"
                        state="{news>state}"
                        frameType="TwoByOne">
                        <tileContent>
                            <TileContent
                                footer="{
                                    path: 'news>date',
                                    formatter: '.formatJSONDate'
                                }">
                                <content>
                                    <NewsContent
                                        contentText="{news>content}"
                                        subheader="{news>subheader}">
                                    </NewsContent>
                                </content>
                            </TileContent>
                        </tileContent>
                    </GenericTile>
                </SlideTile>
            </layout:HorizontalLayout>
```

```
        </layout:VerticalLayout>
    </Page>
</mvc:View>
```

First of all, the `SlideTile` has a wider frame type than the standard `GenericTile`. The default value for the *frameType* property of `GenericTile` is **OneByOne**. This means that it has the standard width and height. The standard frame type of the `SlideTile` is **TwoByOne** which means that the tile is twice as wide as the default one. The data of the **news** model is bound via the **tiles** aggregation and uses the provided `GenericTile` template. All properties in the `GenericTile` are bound to the **news** model. The image you've chosen for the *backgroundImage* property should already have the proper size. As you have all the images you need as part of this tutorial, you only need to refer to the respective image in the model.

With the `NewsContent`, we can put text on top of the background image in the correct layout. In the *NewsContent*, you set the title with the *contentText* property. You set the subtitle using the *subheader* property.

The *date* field in the *news* model is not in a user-friendly format. This is why we are adding a new formatter that converts the date value.

Startpage.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/format/NumberFormat",
    "sap/base/strings/formatMessage"
], function(Controller, JSONModel, NumberFormat) {
    "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
03.controller.Startpage", {
        ...
formatJSONDate: function(date) {
            var oDate = new Date(Date.parse(date));
            return oDate.toLocaleDateString();
        }

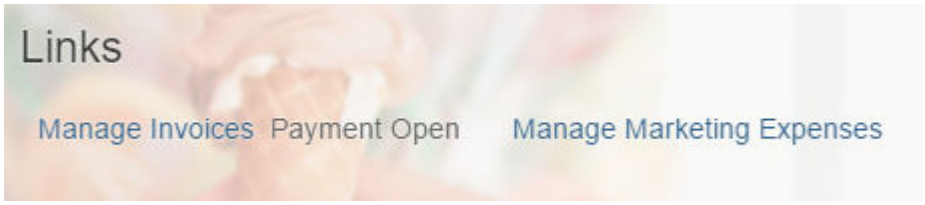
        ...
    });
});
```

In the controller, we need to add the implementation of the *formatJSONDate* formatter function. Based on the language settings of your browser or local machine, the JSON date string is converted to a string that corresponds to the time and date settings.

Step 4: Generic Tiles in Line Mode

In this step, we will create two `GenericTiles` in line mode.

Preview



Two GenericTiles in LineMode

There are tiles that you don't use as often as other tiles. To save space, you can reduce the tiles and only show the header and subheader. Use `LineMode` as the *mode* property of the `GenericTile`.

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 4 - Generic Tiles in Line Mode.

Startpage.view.xml

```
<mvc:View
    controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
04.controller.Startpage"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns="sap.m"
    xmlns:layout="sap.ui.layout"
    xmlns:microchart="sap.suite.ui.microchart">
    <Page title="{i18n>title}">
        <layout:VerticalLayout class="sapUiResponsiveMargin">
            ...
            <Title
                titleStyle="H2"
                text="{i18n>startpageLinksGroupTitle}"
                class="sapUiTinyMarginBegin sapUiMediumMarginTop" />
            <layout:HorizontalLayout allowWrapping="true">
                <GenericTile
                    header="{i18n>startpageLineTile1Title}"
                    subheader="{i18n>startpageLineTile1SubTitle}"
                    mode="LineMode"
                    class="sapUiTinyMarginBegin" />
                <GenericTile
                    header="{i18n>startpageLineTile2Title}"
                    mode="LineMode"
                    class="sapUiTinyMarginBegin" />
            </layout:HorizontalLayout>
        </layout:VerticalLayout>
    </Page>
</mvc:View>
```

We need to create a new layout container for the tiles that we want to show. You do this to separate the two tile types and their alignment. These two tiles can be created in a similar way as the`GenericTiles`, except that the *mode* property must be set to `LineMode`.

Step 5: Navigating from the Start Page to Other Pages

In this step, we will show how to set up navigation using the standard routing pattern.

First, please create three empty views and the corresponding controllers:

- `ProcessFlow.view.xml`
- `ChartContainer.view.xml`
- `Reviews.view.xml`

Startpage.view.xml

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 5 - Navigating from the Start Page to Other Pages.

```
<mvc:View
    ...
    <Page title="{i18n>title}">
        <layout:VerticalLayout class="sapUiResponsiveMargin">
            ...
            <layout:HorizontalLayout allowWrapping="true">
                <GenericTile
                    class="sapUiTinyMarginBegin sapUiTinyMarginTop"
                    header="{i18n>startpagePFTileTitle}"
                    subheader="{i18n>startpagePFTileSubTitle}"
                    press=".onNavToProcessFlow">
                    <tileContent>
                        ...
                    </tileContent>
                </GenericTile>
                    ...
                <GenericTile
                    class="sapUiTinyMarginBegin sapUiTinyMarginTop"
                    header="{i18n>startpageUserReviewsTileTitle}"
                    press=".onNavToReviews">
                    <tileContent>
                        ...
                    </tileContent>
                </GenericTile>
                <GenericTile
                    class="sapUiTinyMarginBegin sapUiTinyMarginTop"
                    header="{i18n>startpageTestResultsTileTitle}"
                    subheader="{i18n>startpageTestResultsTileSubTitle}"
                    press=".onNavToChartContainer">
                    <tileContent>
                        ...
                    </tileContent>
                </GenericTile>
                ...
            </layout:HorizontalLayout>
            ...
        </layout:VerticalLayout>
    </Page>
</mvc:View>
```

We will add the *press* event to the `GenericTiles` with the *Production Process*, *User Reviews*, and *Quality Control* titles. This is to trigger navigation with a function. The press event function will be implemented in the controller file.

Startpage.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/ui/core/format/NumberFormat",
    "sap/base/strings/formatMessage"
], function(Controller, JSONModel, NumberFormat) {
    "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
05.controller.Startpage", {
        ...
        onNavToProcessFlow: function() {
            this.getRouter().navTo("processFlow");
        },

        onNavToChartContainer: function() {
            this.getRouter().navTo("chartContainer");
        },
        onNavToReviews: function() {
            this.getRouter().navTo("reviews");
        },

        getRouter: function() {
            return this.getOwnerComponent().getRouter();
        }
});
```

`getRouter` returns the router instance of the component.

`onNavToProcessFlow` is called when the user clicks on the first tile. It triggers the navigation to the view with the `ProcessFlow`.

`onNavToChartContainer` is called when the user clicks on the fourth tile. It triggers the navigation to the view with the `ChartContainer`.

`onNavToReviews` is called when the user clicks the third tile. It triggers the navigation to the view with the `Timeline`.

Step 6: Chart Container

In this step, we will use the *ChartContainer* control to display information in a detailed view.

In the previous steps, we created a start page with embedded tiles. We prepared the routing configuration for navigation from the *Quality Control* tile to another view.

In the *Quality Control* view, we want to display the temperatures needed for different flavors and the ideal temperature for getting the best ice cream with a smooth consistency. We will use a chart to visualize the data and a table to get a detailed view with the help of the `ChartContainer` control.

Preview

Chart Content

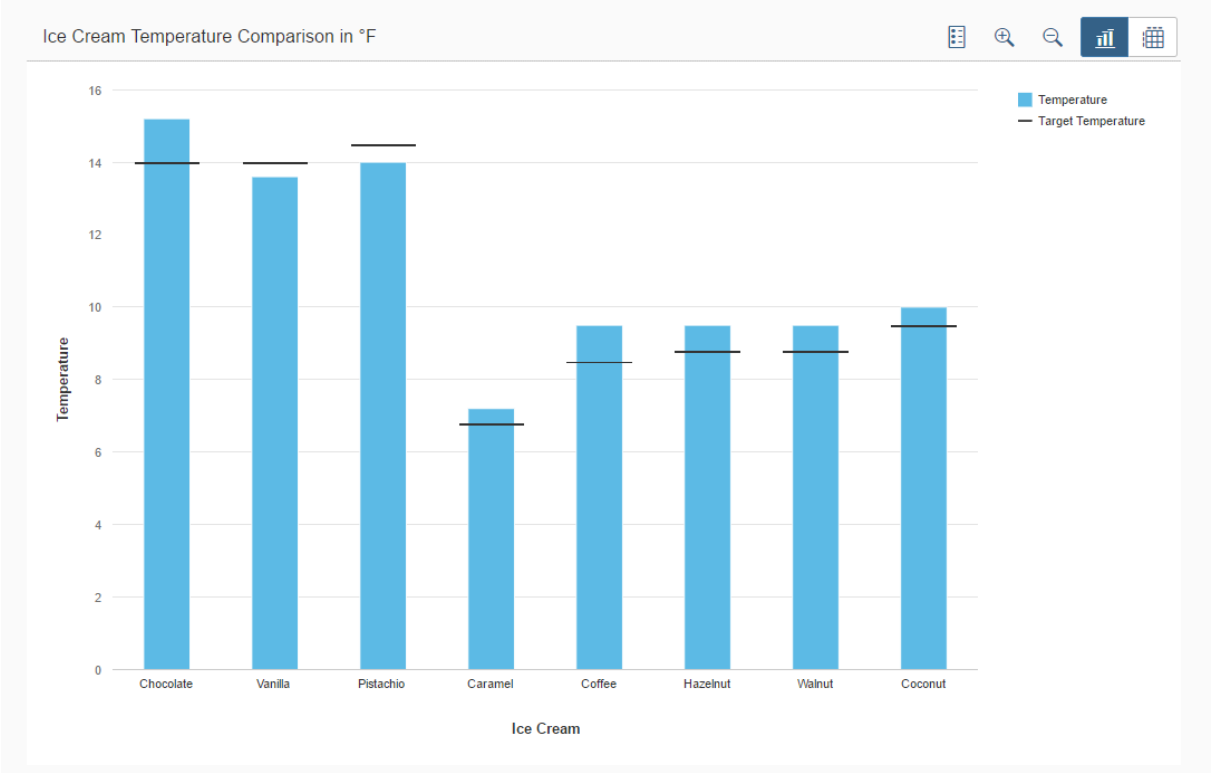


Table Content

Ice Cream Temperature Comparison in °F

Ice Cream ID	Temperature	Target Temperature
Chocolate	15.2	14
Vanilla	13.6	14
Pistachio	14	14.5
Caramel	7.2	6.8
Coffee	9.5	8.5
Hazelnut	9.5	8.8
Walnut	9.5	8.8
Coconut	10	9.5

ChartContainer

The `ChartContainer` control manages various data views in one container. The single controls (for example, *VizFrame* and *Tables*) are embedded in the `ChartContainerContent` controls that were added to the *content* aggregation of the `ChartContainer`.

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 6 - Chart Container.

ChartContainer.view.xml

```
mvc:View
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:suite="sap.suite.ui.commons"
    xmlns:core="sap.ui.core"
    xmlns="sap.m"
    xmlns:l="sap.ui.layout"
    controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
06.controller.ChartContainer">
    <Page
        title="{i18n>chartContainerPageTitle}"
        showNavButton="true"
        navButtonPress=".onNavButtonPressed"
        backgroundDesign="Solid">
        <content>
            <l:Grid defaultSpan="L12 M12 S12" class="sapUiResponsiveMargin"
vSpacing="0" hSpacing="0">
                <suite:ChartContainer
                        title="{
                            parts: [
                                'i18n>chartContainerBulletChartTitle',
                                'business>/temperatureUnit'
                            ],
                            formatter: '.formatMessage'
                        }">
                    <suite:ChartContainerContent
                        icon="sap-icon://vertical-bullet-chart"
                        title="{i18n>chartContainerBulletChartContentTitle}">
                        <suite:content>
                            <core:Fragment

fragmentName="sap.suite.ui.commons.demokit.tutorial.icecream.
06.fragment.VizChart"
                                    type="JS" />
                        </suite:content>
                    </suite:ChartContainerContent>
                </suite:ChartContainer>
            </l:Grid>
        </content>
    </Page>
</mvc:View>
```

In the toolbar, there is a corresponding button for each `ChartContainerContent` from which you can select the content. You can have an icon on the button if you set the *icon* property of the `ChartContainerContent` to the respective SAPUI5 icon URI. The *title* property of the `ChartContainerContent` determines the tooltip text for the button.

Since `VizFrame` is not part of this tutorial, we have provided the `VizChart.fragment.js` JavaScript file in the folder fragment that can be used without modifications.

ChartContainer.controller.js

```
sap.ui.define([
     "sap/ui/core/mvc/Controller"
], function(Controller) {
    "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
06.controller.ChartContainer", {
onNavButtonPressed: function() {
            var oRouter = this.getOwnerComponent().getRouter();
            oRouter.navTo("home");
        }
    });
});
```

In the `ChartContainer.view.xml`, we will add the backward navigation with the `showNavButton` and `navButtonPress` properties. The function that is referenced by the `navButtonPress` event retrieves the router of the component and navigates to the **home** route as specified in `manifest.json`.

Table with details

In the next step, we are going to display detailed information about the data shown in the chart. We will be using a table in which each value is displayed, so that no information is lost.

ChartContainer.view.xml

```
mvc:View
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:suite="sap.suite.ui.commons"
    xmlns:core="sap.ui.core"
    xmlns="sap.m"
    xmlns:l="sap.ui.layout"
    controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
06.controller.ChartContainer">
    <Page
        title="{i18n>chartContainerPageTitle}"
        showNavButton="true"
        navButtonPress=".onNavButtonPressed"
        backgroundDesign="Solid">
        <content>
            <l:Grid defaultSpan="L12 M12 S12" class="sapUiResponsiveMargin"
vSpacing="0" hSpacing="0">
                <suite:ChartContainer
                        title="{
                            parts: [
                                'i18n>chartContainerBulletChartTitle',
                                'business>/temperatureUnit'
                            ],
                            formatter: '.formatMessage'
                        }">
                    ...
                <suite:ChartContainerContent
                     icon="sap-icon://table-chart"
                     title="{i18n>chartContainerTableContentTitle}">
                     <suite:content>
                         <Table items="{/Temperatures}">
                             <columns>
                                 <Column>
                                     <Text
text="{i18n>chartContainerIceCreamId}" />
                                 </Column>
                                 <Column>
                                     <Text
```

```
text="{i18n>chartContainerTemperature}" />
                                    </Column>
                                    <Column>
                                        <Text
text="{i18n>chartContainerTargetTemperature}" />
                                    </Column>
                                </columns>
                                <items>
                                    <ColumnListItem>
                                        <cells>
                                            <Text text="{id}" />
                                            <Text text="{temperature}" />
                                            <Text text="{target}" />
                                        </cells>
                                    </ColumnListItem>
                                </items>
                            </Table>
                        </suite:content>
                    </suite:ChartContainerContent>
                </suite:ChartContainer>
            </l:Grid>
        </content>
    </Page>
</mvc:View>
```

We are going to create another `ChartContainerContent` with a **table**. This table contains three columns that were created with the **Column** element with a **text** that will be shown in the header. The values were created with the `ColumnListItem` that has a *text* control with a bound *text* property for each cell.

Step 7: Header Container and Radial Micro Chart

In this step, we use the `HeaderContainer` and `RadialMicroChart`.

In the last steps, we have implemented the user interaction handling to allow navigation from the **Production Process** tile to the `ProcessFlow` view. With the **Production Process** tile, we only have an aggregated view of the progress of the production process. Therefore, we want to provide a detailed overview of the current production status in this step. We will add the production flow, the states of the manufacturing steps, their dependencies, and critical steps if necessary.

First, we add the `ProcessFlow` control to this view, so that we see the current status of the production process. The production process consists of six steps represented by the following `ProcessFlowLaneHeaders`:

- Order
- Manufacturing
- Assembly
- Marketing
- Delivery
- Payment

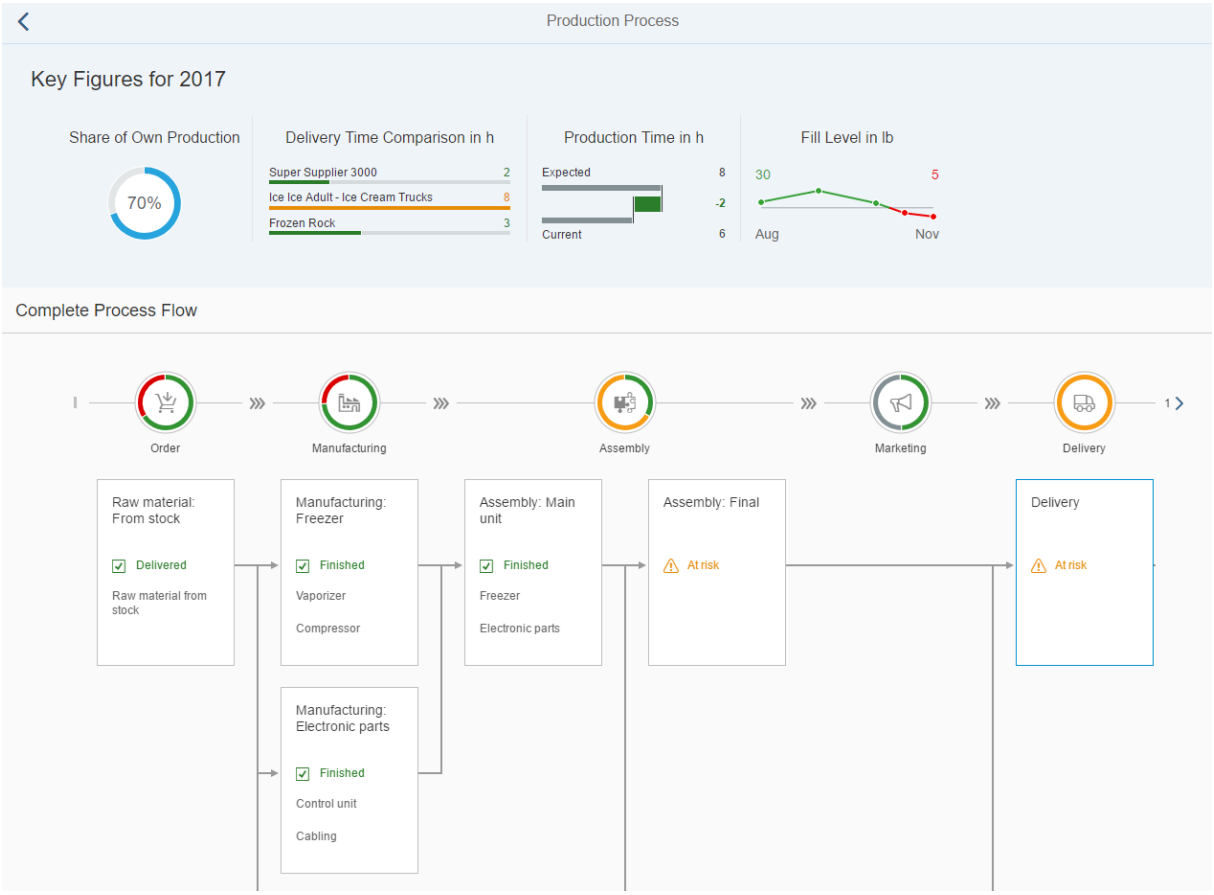
The `ProcessFlowLaneHeaders` use icons that stand for the meaning of the lanes. The lane headers aggregate the status of the nodes that are assigned to a particular lane. Each lane consists of `ProcessFlowNodes` that describe an activity in this production step. The structure of the nodes and their relationships for `ProcessFlow` are defined in the *ProcessFlowData.json* file.

The header area of the `ProcessFlow` should contain a `HeaderContainer` with four micro charts that provide the following information:

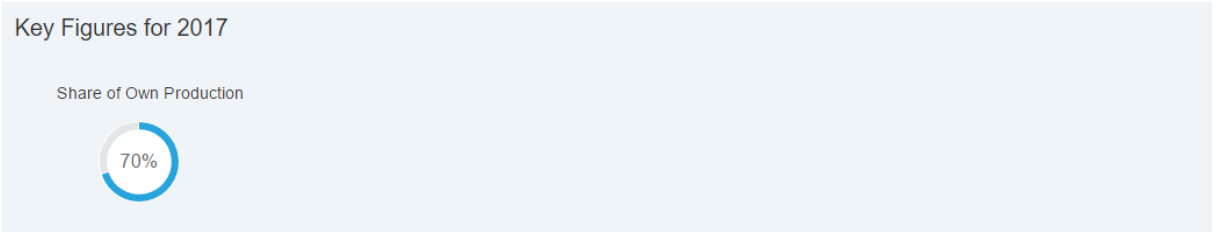
- Share of Own Production (your own production rate)
- Delivery Time Comparison in h (comparison of suppliers' delivery time)
- Production Time in h (comparison of expected and current production times)
- Fill Level in lb (displays the fill level changes over time)

Preview of the final ProcessFlow

This is the final view of this page:



Preview of this step



HeaderContainer with RadialMicroChart

In the header area, we can display additional values for the business logic of the production process. We can use charts to visualize the information. To distinguish this part from the ProcessFlow, we use the *ObjectHeader* in the header area. We want to add further charts in the following steps and therefore, we create an instance of the *HeaderContainer* that contains our charts.

The first chart contains the share of the parts being produced by us that should be included in the final product. This value is already available in the data model. You can visualize the percentage value by using a `RadialMicroChart`. We first create a `HeaderContainer` with a single `RadialMicroChart`.

ProcessFlow.view.xml

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 7 - Header Container and Radial Micro Chart.

```
<mvc:View
    xmlns:mvc="sap.ui.core.mvc"
    xmlns="sap.suite.ui.commons"
    xmlns:m="sap.m"
    xmlns:mc="sap.suite.ui.microchart"
    controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
07.controller.ProcessFlow">
    <m:Page
        title="{i18n>processFlowTitle}"
        showNavButton="true"
        navButtonPress=".onNavButtonPressed"
        backgroundDesign="Solid">
        <m:content>
            <m:ObjectHeader
                responsive="true"
                title="{
                    parts: [
                        'i18n>processFlowChartsTitle',
                        'business>/year'
                    ],
                    formatter: '.formatMessage'
                }">
                <m:headerContainer>
                    <m:HeaderContainer
                        scrollStep="200"
                        scrollTime="500"
                        showDividers="true"
                        class="sapUiSmallMargin">
                        <m:FlexBox
                            width="12rem"
                            height="10rem"
                            alignItems="Center"
                            justifyContent="Center"
                            direction="Column">
                            <m:Title
                                text="{i18n>processFlowChartsShareOwnProduction}"
                                class="sapUiSmallMargin"/>
                            <m:FlexBox width="6rem" height="6rem">
                                <mc:RadialMicroChart percentage="{business>/
shareOwnProduction}"/>
                            </m:FlexBox>
                        </m:FlexBox>
                    </m:HeaderContainer>
                </m:headerContainer>
            </m:ObjectHeader>
        </m:content>
    </m:Page>
```

```
</mvc:View>
```

The `HeaderContainer` has *scrollStep* and *scrollTime* properties that will be used to change the scroll step and the animation speed of the `HeaderContainer`. We keep the *showDividers* default value as we want to split each chart in the `HeaderContainer`.

The `FlexBox` is used as a container for the *Title* and the inner *FlexBox* for the `RadialMicroChart` and this leads to the correct sizing. To visualize the share of your own production, the value should be set in the *percentage* property of the `RadialMicroChart`. With the *Size* enumeration, you can use the chart in one of the fixed sizes. If not set, the default *Responsive* size is used and the width and height will adapt to the surrounding container. We set the *width* and *height* of the *FlexBox* instance.

ProcessFlow.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/base/strings/formatMessage"
], function (Controller, formatMessage) {
    "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
07.controller.ProcessFlow", {
        formatMessage: formatMessage,
        onNavButtonPressed: function () {
            this.getOwnerComponent().getRouter().navTo("home");
        }
    });
});
```

When the user clicks on the **Back** button, *onNavButtonPressed* is called and this triggers the navigation back to the start page view.

Step 8: Comparison Micro Chart

In this step, we will create the `ComparisonMicroChart` on the **Production Process** page.

Preview

ComparisonMicroChart

We would like to include information about our suppliers' delivery times in order to compare them. We are going to use the `ComparisonMicroChart` to visualize the comparison of several values.

ProcessFlow.view.xml

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 8 - Comparison Micro Chart.

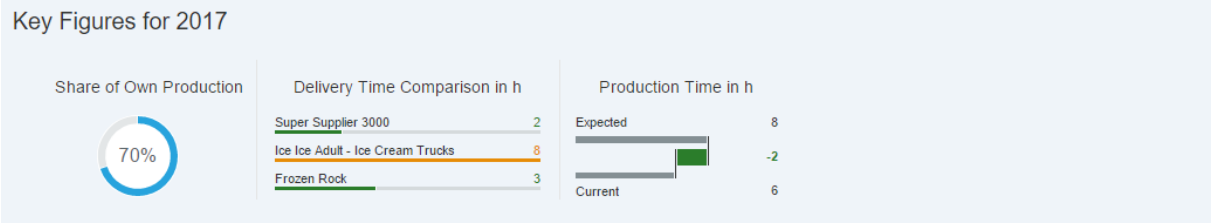
```
mvc:View
    ...
        <m:headerContainer>
            <m:HeaderContainer
                scrollStep="200"
                scrollTime="500"
                showDividers="true"
                class="sapUiSmallMargin">
                ...
                <m:FlexBox
                    width="16rem"
                    height="10rem"
                    alignItems="Center"
                    justifyContent="Center"
                    direction="Column">
                    <m:Title
                        text="{
                            parts: [
                                'i18n>processFlowChartsDeliveryTimeComparison',
                                'suppliers>/timeMeasure'
                            ],
                            formatter: '.formatMessage'
                        }"
                        class="sapUiSmallMargin" />
                    <m:FlexBox width="16rem" height="6rem" renderType="Bare">
                        <mc:ComparisonMicroChart
                            size="Responsive"
                            press=".press"
                            data="{suppliers>/Suppliers}">
                            <mc:data>
                                <mc:ComparisonMicroChartData
                                    title="{suppliers>id}"
                                    value="{suppliers>deliveryTime}"
                                    displayValue="{suppliers>deliveryTime}"
                                    color="{suppliers>deliveryTimeSemantics}" />
                            </mc:data>
                        </mc:ComparisonMicroChart>
                    </m:FlexBox>
                </m:FlexBox>
            </m:HeaderContainer>
        </m:headerContainer>
</mvc:View>
```

The structure that surrounds the `ComparisonMicroChart` is similar to the structure we used for the `RadialMicroChart`. The chart dimensions are inherited from *FlexBox* because the *isResponsible* property is being used. The internal structure is different because the `ComparisonMicroChart` contains an aggregation of the `ComparisonMicroChartData` items. Each item is responsible for a particular line in the chart.

Step 9: Delta Micro Chart

In this step, we will create the `DeltaMicroChart` on the **Production Process** page.

Preview



DeltaMicroChart

We are going to add a chart to visualize the difference between the time required for production compared with the estimated time. You use the `DeltaMicroChart` to compare two separate values.

ProcessFlow.view.xml

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 9 - Delta Micro Chart.

```
mvc:View
    ...
        <m:headerContainer>
            <m:HeaderContainer
                scrollStep="200"
                scrollTime="500"
                showDividers="true"
                class="sapUiSmallMargin">
                ...
                <m:FlexBox
                    width="12rem"
                    height="10rem"
                    alignItems="Center"
                    justifyContent="Center"
                    direction="Column">
                    <m:Title
                        text="{
                            parts: [
                                'i18n>processFlowChartsProductionTime',
                                'business>/timeMeasure'
                            ],
                            formatter: '.formatMessage'
                        }"
                        class="sapUiSmallMargin" />
                    <m:FlexBox width="12rem" height="6rem" renderType="Bare">
                        <mc:DeltaMicroChart
                            size="Responsive"
                            color="{business>/
productionTimeComparisonCriticality}"
                            value1="{business>/expectedProductionTime}"
```

```
                            value2="{business>/currentProductionTime}"
                            title1="{i18n>processFlowChartsExpected}"
                            title2="{i18n>processFlowChartsCurrent}"
                            displayValue1="{business>/expectedProductionTime}"
                            displayValue2="{business>/currentProductionTime}"
                            deltaDisplayValue="{
                                parts: [
                                    'business>/expectedProductionTime',
                                    'business>/currentProductionTime'
                                ],
                                formatter: '.getValuesDelta'
                        }" />
                    </m:FlexBox>
                </m:FlexBox>
            </m:HeaderContainer>
        </m:headerContainer>
    ...
</mvc:View>
```

The `DeltaMicroChart` is used in the responsive mode embedded in the *Flexbox* that sets the dimensions. We are simply using the respective values from the data model for binding the *displayValue1* and *displayValue2* properties. For the *deltaDisplayValue*, we need to perform an advanced calculation based on the values before we can set them as a property. This is why we will be using the *.getValuesDelta* formatter function.

ProcessFlow.controller.js

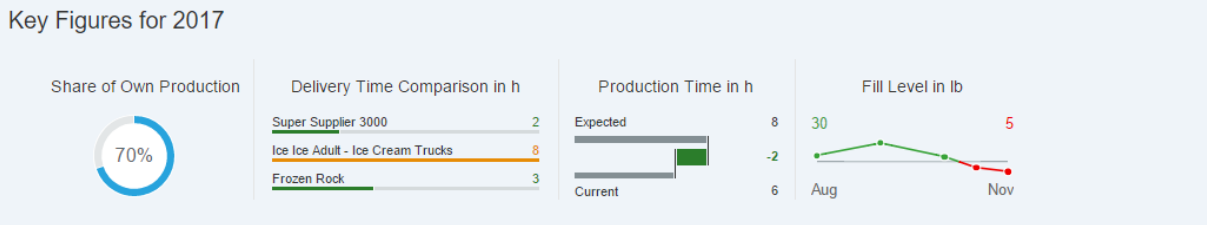
```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/base/strings/formatMessage"
], function(Controller) {
    "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
09.controller.ProcessFlow", {
        ...
        getValuesDelta: function(fFirstValue, fSecondValue) {
            return fSecondValue - fFirstValue;
        }
    });
});
```

This formatter takes the respective values and returns a string that will then be set as a property of the `DeltaMicroChart`.

Step 10: Line Micro Chart

In this step, we will create the `LineMicroChart` on the **Production Process** page.

Preview



LineMicroChart

With the `LineMicroChart`, we want to visualize how the fill level is going to change during the course of the production process and we want to determine the threshold values that fall below a specified level.

ProcessFlow.view.xml

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 10 - Line Micro Chart.

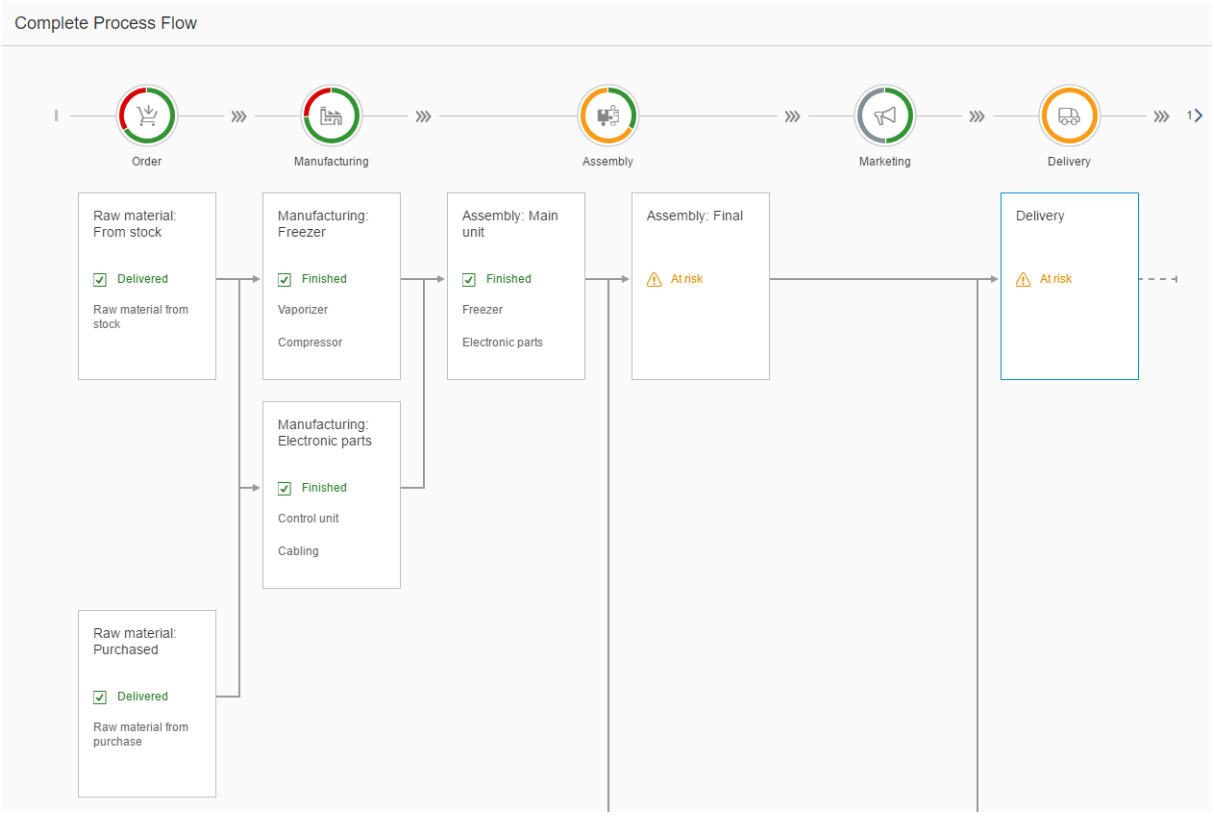
```
mvc:View
    ...
        <m:headerContainer>
            <m:HeaderContainer
                scrollStep="200"
                scrollTime="500"
                showDividers="true"
                class="sapUiSmallMargin">
                ...
                <m:FlexBox
                    width="12rem"
                    height="10rem"
                    alignItems="Center"
                    justifyContent="Center"
                    direction="Column">
                    <m:Title
                        text="{
                            parts: [
                                'i18n>processFlowChartsFillLevel',
                                'business>/fillLevel/measure'
                            ],
                            formatter: '.formatMessage'
                        }"
                        class="sapUiSmallMargin" />
                    <m:FlexBox width="12rem" height="6rem" renderType="Bare">
                        <mc:LineMicroChart
                            size="Responsive"
                            threshold="{business>/fillLevel/threshold}"
                            leftTopLabel="{business>/fillLevel/valueBegin}"
                            leftBottomLabel="{business>/fillLevel/timeBegin}"
                            rightTopLabel="{business>/fillLevel/valueEnd}"
                            rightBottomLabel="{business>/fillLevel/timeEnd}"
                            color="{business>/fillLevel/color}"
                            showPoints="true"
                            points="{
                                path: 'business>/fillLevel/timeSeries',
                                templateShareable: true
                            }">
                            <mc:LineMicroChartPoint
                                x="{business>time}"
                                y="{business>level}" />
                        </mc:LineMicroChart>
                    </m:FlexBox>
                </m:FlexBox>
            </m:HeaderContainer>
        </m:headerContainer>
    ...
</mvc:View>
```

You can find the information about the fill levels in the *points* aggregation of the `LineMicroChart` control. Property **x** of the `LineMicroChartPoint` contains the dimension of the chart and the time. Property **y** contains the fill level during the production process. The **threshold** property separates the records by their fill level into an upper and a lower layer. With the *color* property, we can apply a different color to each layer, depending on the specified threshold.

Step 11: Process Flow

In this step, we will create the `ProcessFlow` on the **Production Process** page.

Preview



ProcessFlow

The `ProcessFlow` in the center of the page will be used to visualize the current state of the production process. Each production step is represented by a lane. The colors of the state segments of `ProcessFlowHeader` are calculated internally according to a `ProcessFlowNode` of a lane. The following semantic colors are used:

- Grey for **Neutral**
- Green for **Good**
- Orange for **Critical**
- Red for **Error**.

The **Assembly** lane in the middle is a *merged* lane that consists of nodes that are bound together by a parent-child relation. As a result, the usual width will be doubled.

The `ProcessFlowNode` elements **Spare parts: Purchased** and **Delivery** are highlighted (refer to the *focused* property on the API). They are of high interest because their states are critical.

ProcessFlow.view.xml

You can view and download this step in the Demo Kit at Process Flow.

```
<mvc:View
    ...
        <m:ObjectHeader
            ...
            <m:headerContainer>
                <m:HeaderContainer
                    ...
                </m:HeaderContainer>
            </m:headerContainer>
        </m:ObjectHeader>
        <m:Panel headerText="{i18n>processFlowProcessTitle}">
            <ProcessFlow
                id="processflow1"
                scrollable="false"
                nodes="{process>/Nodes}"
                lanes="{process>/Lanes}"
                nodePress=".onNodePressed">
                <nodes>
                    <ProcessFlowNode
                        laneId="{process>lane}"
                        nodeId="{process>id}"
                        title="{process>title}"
                        titleAbbreviation="{process>titleAbbreviation}"
                        isTitleClickable="{process>isTitleClickable}"
                        children="{process>children}"
                        state="{process>state}"
                        stateText="{process>stateText}"
                        texts="{process>texts}"
                        highlighted="{process>highlighted}"
                        focused="{process>focused}" />
                </nodes>
                <lanes>
                    <ProcessFlowLaneHeader
                        laneId="{process>id}"
                        iconSrc="{process>icon}"
                        text="{process>label}"
                        position="{process>position}" />
                </lanes>
            </ProcessFlow>
        </m:Panel>
    ...
</mvc:View>
```

First, we are going to add a `ProcessFlow` control to our view. By setting the *scrollable* property to **false**, the `ProcessFlow` will use the default browser scrolling.

Next, we will bind the *nodes* and *lanes* aggregations. Templates will be added to the corresponding aggregations (nodes and lanes).

The template for `ProcessFlowNodes` is created using the following properties:

- The *laneId* that is a unique identifier for the lane the node belongs to.
- The *nodeId* that is the current node identifier.
- The **child** property that defines the parent-child relation to other nodes using their *nodeIds*.
- The **state** property that determines the property of the node and influences the aggregated state of the lane directly.

The next template for the lanes will be created using a `ProcessFlowLaneHeader` with a *laneId* that we already know from the `ProcessFlowNode`. The *iconSrc* property of the `ProcessFlowLaneHeader` accepts any icon. The text below the state of the `ProcessFlowLaneHeader` is set with the *text* property of the lane header. The order of the lanes is defined by the *position* property of the lane header.

ProcessFlow.controller.js

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageToast",
    "sap/base/strings/formatMessage"
], function(Controller, MessageToast) {
    "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
11.controller.ProcessFlow", {
        ...
        onNodePressed: function(oEvent) {
             var sItemTitle = oEvent.getParameters().getTitle();

MessageToast.show(this.getResourceBundle().getText("processFlowNodeClickedMessage
", [sItemTitle]));
        },

        getResourceBundle: function() {
            return this.getOwnerComponent().getModel("i18n").getResourceBundle();
        }
    });
});
```

The *onNodePressed* event listener is set on the *onNode* event of the `ProcessFlow`. It is called when the user clicks on the *node*. The title text of the *node* will be displayed in the message toast.

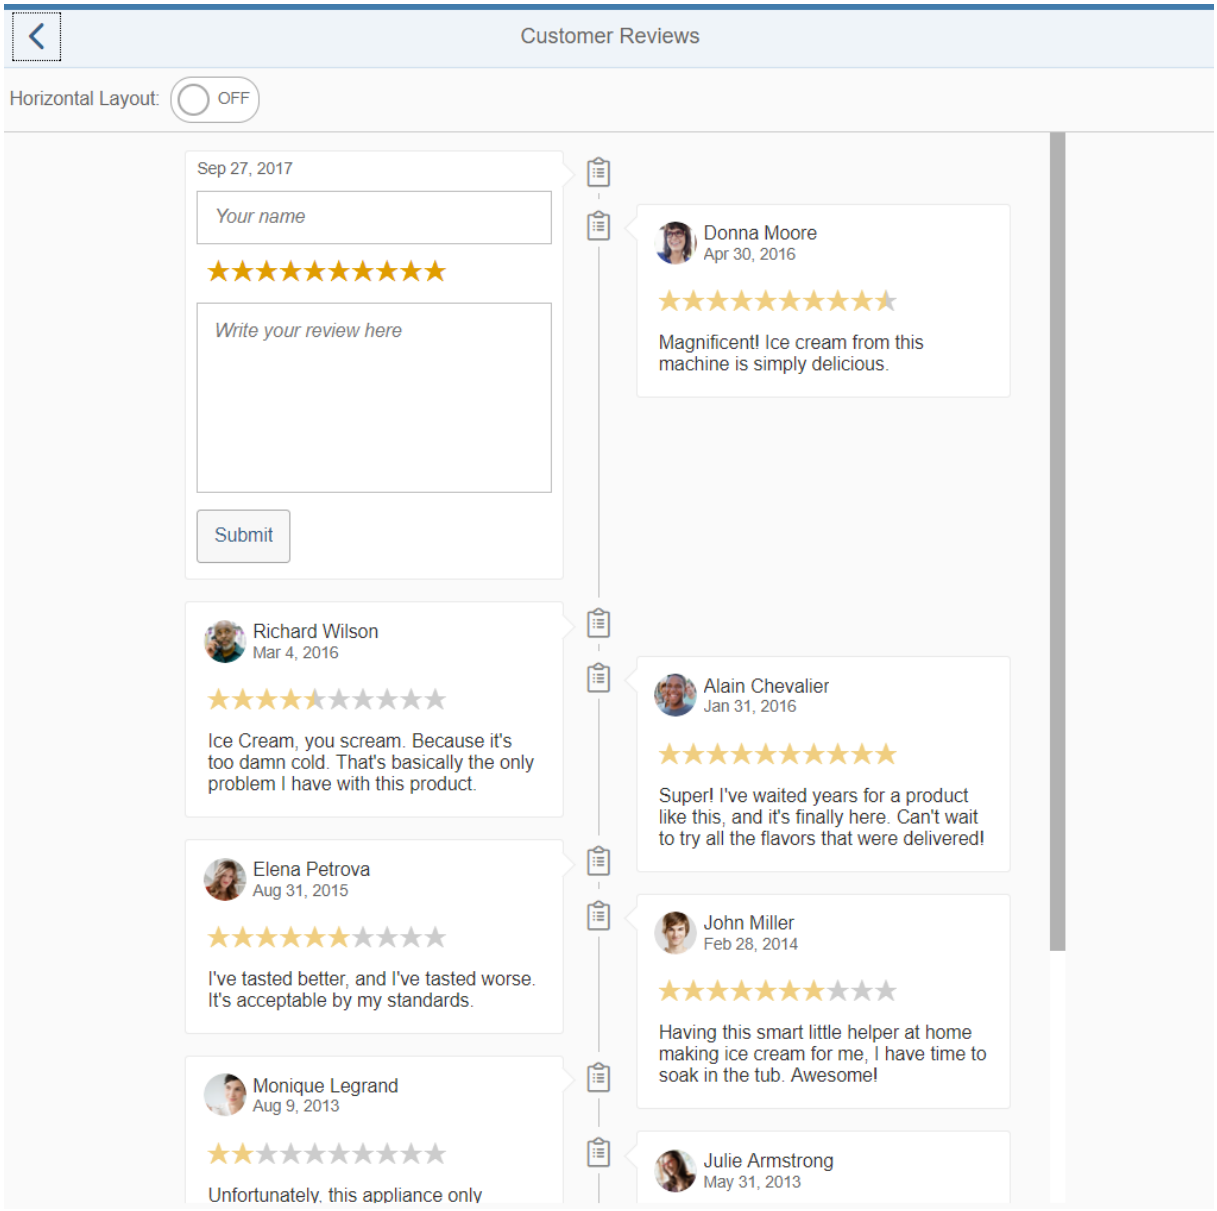
Step 12: Timeline

Use this step to learn how to set up a page where your customers can post their reviews of the ice cream machine.

In this step, we will use the `Timeline` control that allows the users to write and submit reviews. The reviews are arranged in chronological order along the timeline axis.

You can view and download this step in the Demo Kit at Ice Cream Machine - Step 12 - Timeline.

Preview



Setting Up a Reviews Page with a Timeline

To perform this step, you need one of the views you created in step 5, `Reviews.view.xml`, as well as the controller you defined for this view, `Reviews.controller.js`.

Reviews.view.xml

In the `Reviews.view.xml` view, add a `Timeline` element that will display a timeline with customer reviews.

You may also need to add a `page` and a `toolbar` if the view does not include them yet.

```
<mvc:View
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc"
    xmlns:suite="sap.suite.ui.commons"
    controllerName="sap.suite.ui.commons.demokit.tutorial.icecream.
12.controller.Reviews">
    <Page
        title="{i18n>timelineTitle}"
        showNavButton="true"
        navButtonPress=".onNavButtonPressed"
        backgroundDesign="Solid">
        <Toolbar>
            <Label text="{i18n>layoutSwitchLabel}"/>
            <Switch change=".onHorizontalSwitchChange"/>
        </Toolbar>
        <suite:Timeline
            id="timeline"
            enableDoubleSided="true"
            growing="false"
            groupBy="dateTime"
            lazyLoading="true"
            content="{reviews>/UserReviews}"
            textHeight="automatic"
            showHeaderBar="false">
            <suite:TimelineItem
                dateTime="{
                    path: 'reviews>date',
                    formatter: '.formatDateTime'
                }"
                userPicture="{=!${reviews>template} ? ${reviews>userPic} : null}"
                title="{=!${reviews>template} ? ${reviews>user} : null}"
                text="{=!${reviews>template} ? ${reviews>quote} : null}"
                filterValue="{=!${reviews>template} ? ${reviews>rating} : null}">
                <suite:embeddedControl>
                    <VBox>
                        <Input
                            value="{reviews>user}"
                            visible="{reviews>template}"
                            placeholder="{i18n>newReviewUserNameHint}"/>
                        <RatingIndicator
                            enabled="{reviews>template}"
                            value="{reviews>rating}"
                            maxValue="10"
                            iconSize="1rem"
                            class="sapUiTinyMargin"/>
                        <Text
                            text="{reviews>quote}"
                            visible="{=!${reviews>template}}"
                            class="sapUiTinyMargin"/>
                        <TextArea
                            value="{reviews>quote}"
                            growing="false"
                            height="150px"
                            width="100%"
                            visible="{reviews>template}"
                            placeholder="{i18n>newReviewUserCommentHint}"
                            valueLiveUpdate="true"/>
                        <Button
                            visible="{reviews>template}"
                            text="{i18n>newReviewButtonText}"
                            press=".addReview"/>
                    </VBox>
                </suite:embeddedControl>
            </suite:TimelineItem>
        </suite:Timeline>
    </Page>
```

```
</mvc:View>
```

Reviews.controller.js

In the reviews controller, define a function for adding a review, `addReview`, along with the functions for adjusting date and time format, `formatDateTime`, dynamically updating the rating, `onRatingChange`, layout switching, `onHorizontalSwitchChange`, and navigating back to the start page, `onNavButtonPressed`.

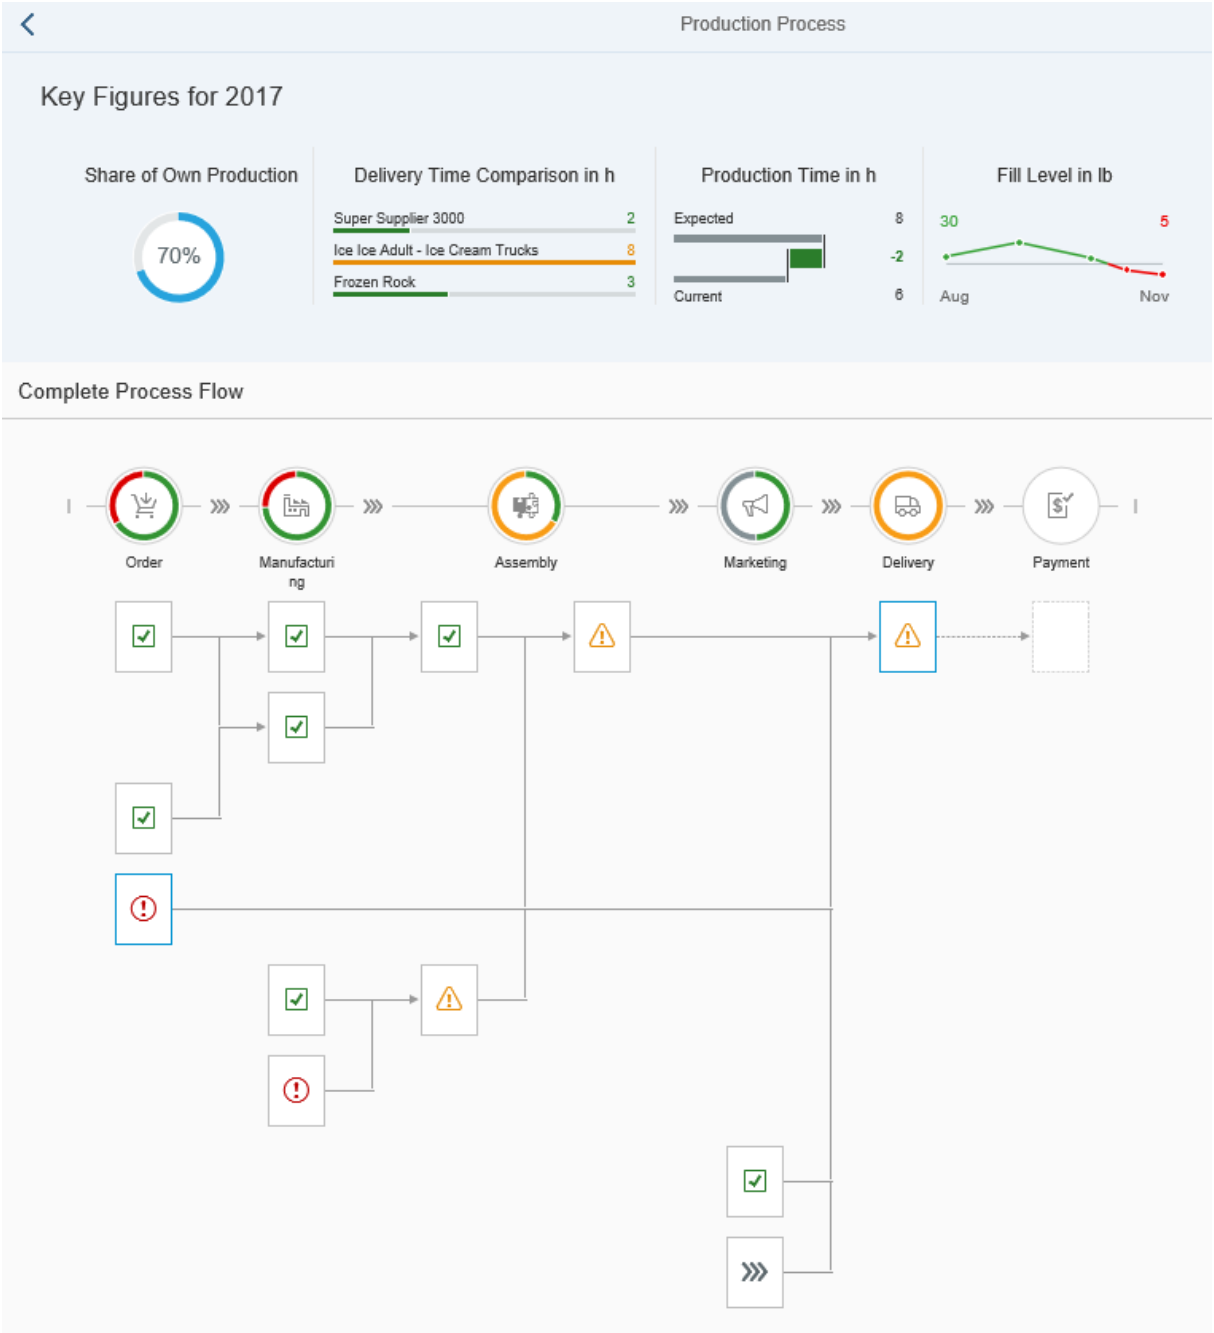
```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/core/format/DateFormat"
], function(Controller, DateFormat) {
    "use strict";
    return Controller.extend("sap.suite.ui.commons.demokit.tutorial.icecream.
12.controller.Reviews", {
        onInit: function() {
            this.oTimeline = this.byId("timeline");
        },
        addReview: function() {
            var oModel = this.getView().getModel("reviews"),
                oData = oModel.getData(),
                oTemplateEntry = oData.UserReviews[0];
            oTemplateEntry.template = false;
            // Add new template entry to the beginning
            oData.UserReviews.unshift({
                "user": "",
                "userPic": "",
                "rating": 10,
                "quote": "",
                "dateTime": "now",
                "template": true
            });
            oModel.setData(oData);
        },
        formatDateTime: function(dateTime) {
            var oDateInstance = DateFormat.getDateInstance();
            return oDateInstance.format(oDateInstance.parse(dateTime));
        },
        onNavButtonPressed: function() {
            var oRouter = this.getOwnerComponent().getRouter();
            oRouter.navTo("home");
        },
        onHorizontalSwitchChange: function(event) {
            if (event.getParameter("state")) {
                this.oTimeline.setAxisOrientation("Horizontal");
            } else {
                this.oTimeline.setAxisOrientation("Vertical");
            }
        }
    });
});
```

The initial reviews data is pulled from the model data in the */model/data/Reviews.json* file that is included in the download materials for this tutorial.

Step 13: Optimizing the Process Flow Layout

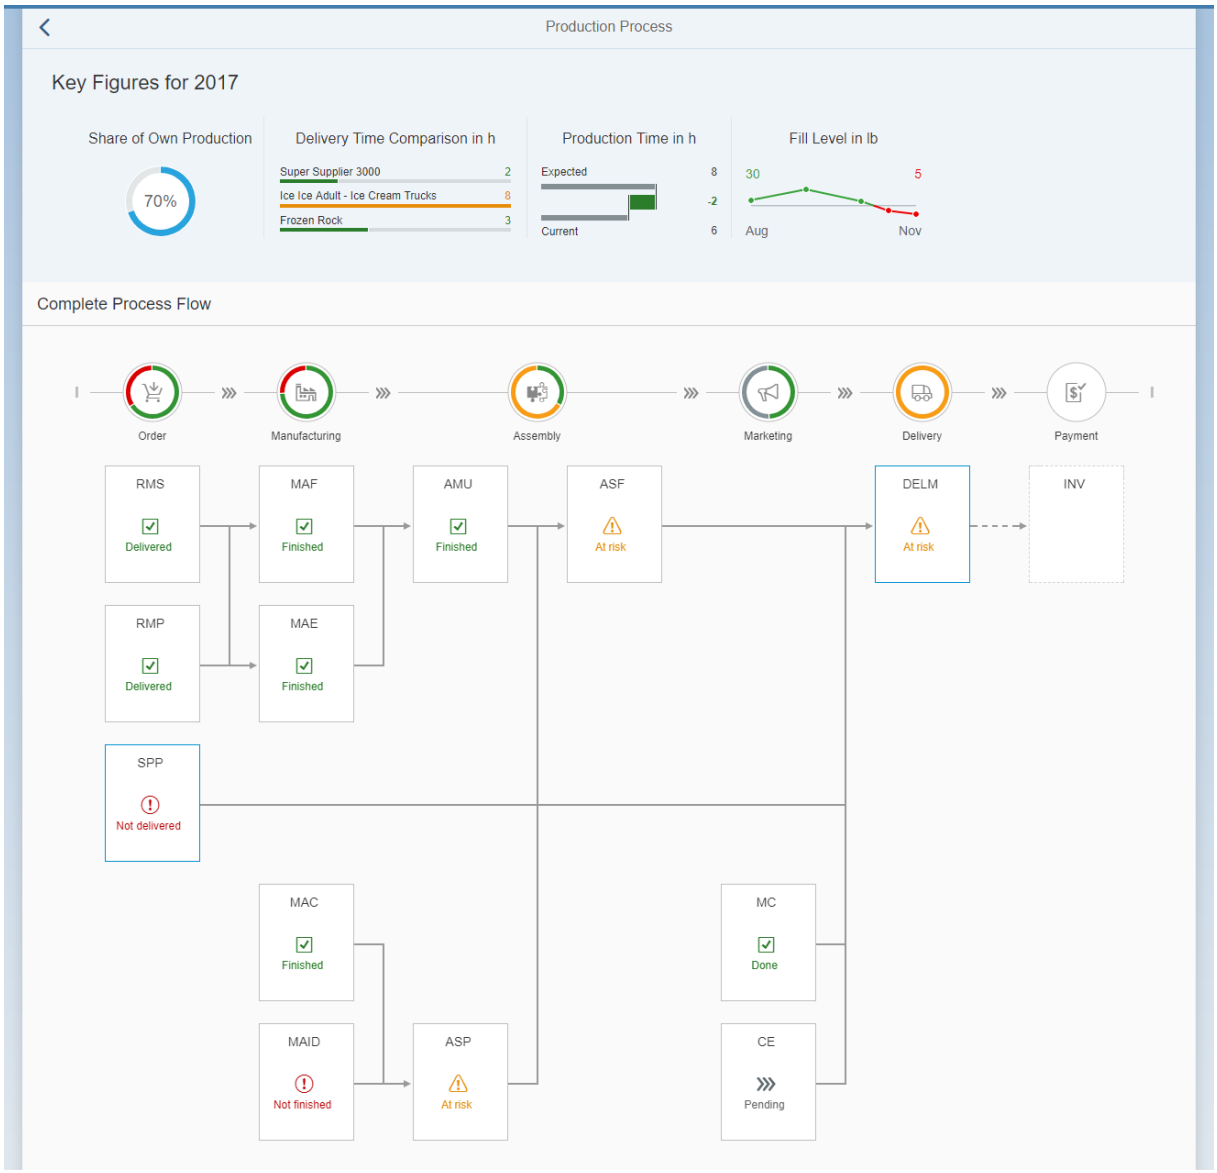
In the last step, we will optimize the `ProcessFlow` layout.

When you have completed the previous steps, your **Production Process** page will look like this:



You may have seen that some `ProcessFlow` nodes are not placed in a perfect way. For example, there is too much space for the *Marketing* node and available space is not used. To optimize the position of the nodes, the

`ProcessFlow` control provides the *optimizeLayout* API method. With this method, you can rearrange the nodes. Check it out and see the results:



Please keep in mind that this optimization has an influence on the app performance as rendering times will increase.

For more information, see the API Reference in the Demo Kit.

Demo Apps

With the Demo Kit, we deliver some demo apps that show you how you can use the various features and controls of SAPUI5.

You can open the apps directly at Demo Apps. You can also download the source files there to have a look at the code.

We have the following categories of demo apps:

- Showcase apps that show you how to use specific controls or features
- Apps that are created with our tutorials (see Get Started: Setup, Tutorials, and Demo Apps [page 38])
- Template apps (see App Templates: Kick Start Your App Development [page 1399])
- Other demo apps for Key User Adaptation, Application Path Framework (APF), and Charts

The following tables give an overview of what each demo app shows.

Features, Layouts, and Specific Topics

Demo App	Feature	Layouts	Specific Topic

Shopping Cart	XML View [page 787]
	Busy Indicators [page 2253]

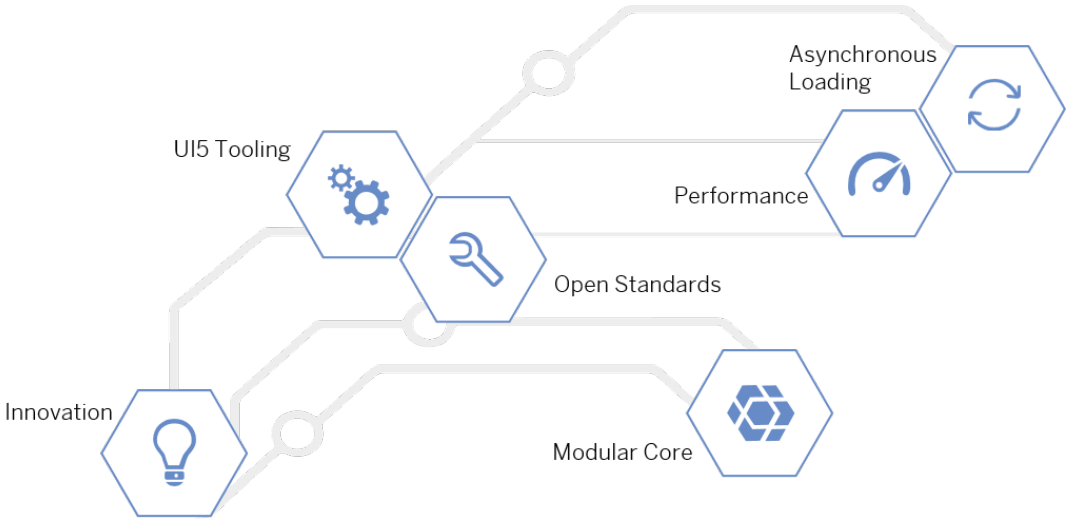
Best Practices for App Developers

In this section, we have compiled a set of best practice recommendations to help you develop high-quality SAPUI5 apps.

The best practices articles are built around the key concepts below. Where applicable, we show hands-on examples and refer you to our tutorials as well as to our the detailed documentation.

Key Concepts

Hover over the shapes to find out more about some key benefits of SAPUI5.



- Best Practices for App Developers [page 680]
- Best Practices for App Developers [page 680]
- Best Practices for App Developers [page 680]
- Best Practices for App Developers [page 680]
- Best Practices for App Developers [page 680]
- Best Practices for App Developers [page 680]

> → Tip
>
> All demo apps, templates, and tutorials in the SAPUI5 Demo Kit follow these recommendations.

Load Only What You Really Need

The amount of resources and data that your app loads will directly affect the performance of your app. You should declare all dependencies and remove unused libraries and classes from your code.

Keep Your Library Dependencies Up To Date

A library preload file, the library styles and text translations are loaded for every library you define in the application descriptor or the SAPUI5 bootstrap. Always define libraries in the manifest and remove all libraries that you do not intend to use in your code.

```
"sap.ui5": {
    "dependencies": {
        "minUI5Version": "1.60.0",
        "libs": {
            "sap.ui.core": {},
            "sap.m": {},
```

```
            "sap.ui.layout": {}
        }
    }
    ...
}
```

- Learn how: Walkthrough Tutorial Step 10: Descriptor for Applications [page 91]
- Find out more: Descriptor for Applications, Components, and Libraries [page 734]

Declare Local Dependencies

In the JavaScript files of your app, define all dependencies to SAPUI5 framework classes and app resources via `sap.ui.define`. If you have unused dependencies, you should remove them right away.

The UI5 Build and Development tooling can then create a "cleaned-up" version of your app that only contains the resources you really need. The so-called application preload will greatly speed up the initial load time of your app.

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/m/MessageToast",
    "sap/base/Log"
], function (Controller, MessageToast, Log) {
    ...
```

- Learn how: Walkthrough Tutorial Step 10: Descriptor for Applications [page 91]
- Find out more:
  - Modules and Dependencies [page 1094]

  - https://github.com/SAP/ui5-tooling

Use Lazy Loading

Use controls like `sap.m.List` or UI patterns that support displaying data selectively or with pagination. Make sure that your backend service is designed to deliver small chunks of data as well.

```
<List
    growing="true"
    growingThreshold="20"
    ...>
```

- Learn how: Testing Tutorial Step 7: Changing the Table to a Growing Table [page 399]
- Find out more: Growing Feature for Table and List [page 2342]

Use the MVC Concept

MVC (Model-View-Controller) is a concept for structuring your software. It makes it easier to maintain and to extend your apps.

The MVC pattern divides your application into three individual parts that interact with each other: the model, the views, and the controllers. There are some best practices for each of these parts:

Model: Keep Everything Organized

It's simple: Use the right folder structure! If you arrange and structure your files and folders in a smart way, this makes coding much easier and also makes for sound performance when you load your application.

- Find out more: Folder Structure: Where to Put Your Files [page 1428]

View: Use XML Views

There are many view types, for example JavaScript, JSON, or HTML. However, we strongly recommend that you use XML views and fragments. XML clearly separates the view and the application logic, is easy to manipulate and can be parsed by tools like the layout editor in SAP Web IDE. That's why we also used XML views in all our tutorials, demo apps, and guides.

- Learn how: Walkthrough Tutorial Step 4: XML Views [page 76]
- Find out more: XML View [page 787]

Controller: Find the Best Location for Your Controllers

Every view you create should have its own controller with a corresponding file name. For example: If your view is called `App.view.xml`, then the matching controller should be named `App.controller.js`.

There is one special case: The so called `BaseController` is not directly related to a view. It is quite common that several controllers use the same functions. You can place these shared functions in the `BaseController` from which all other instantiated controllers will inherit. In other words: Every function you place in the `BaseController` is available for all your controllers. This makes your app code definitely easier to maintain, and you save some lines of code!

The controllers are written in JavaScript and contain all the app logic. They should be placed in the `controller` folder. However, not all JavaScript code belongs in the `controller` folder. For example, formatter logic. The main function of this type of JavaScript file is to format data. That's why you should place it in the `models` folder of your application.

- Learn how: Walkthrough Tutorial Step 5: Controllers [page 79]
- Find our more: Controller [page 807]

Keep Your Views Short and Simple

The view part of your app reflects what users can see and interact with. You should use a suitable set of UI controls that match your scenario and keep things simple.

Use `sap.m` as the Default Namespace

Most bread-and-butter controls are located in the `sap.m` namespace, which makes it the perfect default namespace. If you want to add other controls and layouts, you can define an additional namespace. For your own namespaces, you should keep the alias short and simple as well. You will typically use it in many places, and a short alias keeps your code tidy.

```
<mvc:View
    xmlns="sap.m"
    xmls:l="sap.ui.layout"
    xmlns:mvc="sap.ui.core.mvc">
    <App>
        <Page>
            <l:HorizontalLayout>
            ...
```

- Find out more: Namespaces in XML Views [page 788]

Remove Clutter From Your Views

It's easy to save a few bytes and make your code a lot cleaner:

- Don't define properties that are set to their default values.
- Remove unused namespace aliases.
- Omit the `content` or `items` tag for controls that define default aggregations.
- Use self-closing XML tags for controls that don't define any aggregations.

> → Tip
>
> Samples may contain more code that you actually need. When you copy code from a sample, it's best to remove all properties that won't be used in your views.

```
<SearchField change=".onSearch"/>
<List items="{/Products}" headerText="Search Results">
    <StandardListItem title="{Name}"/>
</List>
</Panel>
```

Clean Up Your Aggregation Templates

If you have bound aggregations, Avoid using complex or nested controls. Remember: The template below will be repeated for every entity in your data. If the template is more complex than necessary, this may lead to performance issues at runtime and slow down your app.

```
<List
    items={/Products}>
    <StandardListItem
        title="{Name}"
        description="{Text}"/>
```

- Learn how: Data Binding Tutorial Step 12: Aggregation Binding Using Templates [page 244]
- Find out more: Aggregation Handling in XML Views [page 788]

Think About View Modularization Early On

Things may get a little messy as your app is growing with your requirements. Therefore, name your views semantically. If a view is getting too "heavy", you should outsource parts of it to a separate view. With XML fragments and XML composites, you can flexibly reuse parts of yor UI elsewhere.

```
<App>
    <Page>
        <myXMLComposites:SearchPanel title="Find employees"/>
        <mvc:XMLView viewName="EmployeList"/>
    </Page>
</App>
```

- Learn how: Walkthrough Tutorial Step 15: Nested Views [page 104]
- Find out more:
  - XML Composite Controls [page 2229]
  - Reusing UI Parts: Fragments [page 1004]

Choose Clever UI Patterns

SAPUI5 offers a huge collection of feature-rich UI controls, often giving you multiple implementation choices.

Aim for the simplest possible pattern to implement your use case. For more information, see the Samples, and filter for "layout".

Use Stable IDs

If you keep the IDs of controls, elements, and components stable, you can be sure that other SAPUI5 features will be able to identify them correctly during processing.

Background

SAPUI5generates IDs for controls, elements, or components dynamically if you don't set them yourself. This sounds convenient, but might lead to problems when the corresponding elements are processed later on by other SAPUI5 features. So it's a good idea to use stable IDs instead of dynamic IDs.

How to Make IDs Stable

For this, you use the `id` property or attribute of the respective element. For a list of the elements for which you can set stable ID, see the related link below.

Here's an example of an XML view **without** stable IDs:

```
<mvc:View
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page>
        <content>
            <Table>
            </Table>
        </content>
    </Page>
</mvc:View>
```

At runtime, the `Page` and the `Table` would get dynamically generated IDs like `__page0` and `__table0`. However, these generated IDs can change whenever the control structure of the app changes.

If you define stable IDs for the two controls in the example above, it could look like this:

```
<mvc:View
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Page id="page">
        <content>
            <Table id="table">
            </Table>
        </content>
    </Page>
</mvc:View>
```

The controls will now always be identified by these IDs.

In the case of views, the sequence of instantiation also plays a role: If there are two views with unstable IDs in the app, they get the generated IDs `__view0` and `__view1` depending on the order the views are opened. This makes it impossible to correctly identify them when they are processed by other features.

→ Tip

You should choose a semantic name for your IDs that makes it easier for you to identify them later.

For more information about naming restrictions, some testing options to check for unstable IDs, as well as the features that require stable IDs, see the related link below.

Related Information

Stable IDs: All You Need to Know [page 1442]

Make Your App CSP Compliant

CSP stands for Content Security Policy and is a security standard to prevent cross-site scripting or other code injection attacks.

It's strongly recommended that you make your SAPUI5 applications CSP compliant - after all, you want your apps to be secure. The main thing you have to do is to remove all scripts that directly execute code from your HTML pages.

Define Initial Components in a Declarative Way

Don't use directly executable code in your HTML files, because this makes them vulnerable. Instead, enable the `ComponentSupport` module in the bootstrapping script. Then, declare your desired component in the body via a `div` tag. This will instantiate the component when the `onInit` is executed.

```
...
<script id="sap-ui-bootstrap"
    src="resources/sap-ui-core.js"
    data-sap-ui-preload="async"
    data-sap-ui-theme="sap_belize"
    data-sap-ui-oninit="module:sap/ui/core/ComponentSupport">
</script>
<body class="sapUiBody" id="content">
    <div data-sap-ui-component data-name="sap.ui.demo.walkthrough" data-
id="container" data-settings='{"id" : "walkthrough"}'></div>
</body>
```

- Learn how: Walkthrough Tutorial Step 9: Component Configuration [page 88]
- Find our more: Declarative API for Initial Components [page 731]

Separate Scripts From HTML Files in Your Test Folder

Because the HTML files in your test folder do not directly open your application, you can't use the new `ComponentSupport` feature here. To make them CSP compliant, you need to put the executable script code in

a separate file on the same level as the HTML file. You can then refer to this file in your HTML file inside a `script` tag in the head:

New script file:

```
window.suite = function() {
    "use strict";
    var oSuite = new parent.jsUnitTestSuite(),
        sContextPath = location.pathname.substring(0,
location.pathname.lastIndexOf("/") + 1);
    oSuite.addTestPage(sContextPath + "unit/unitTests.qunit.html");
    oSuite.addTestPage(sContextPath + "integration/opaTests.qunit.html");
    return oSuite;
};
```

HTML file:

```
<head>
    ...
    <script src="testsuite.qunit.js" data-sap-ui-testsuite></script>
</head>
</html>
```

- Learn how: Testing Tutorial Step 10: Test Suite and Automated Testing [page 411]
- Find out more: Content Security Policy [page 1481]

Use Asynchronous Loading

Asynchronous loading is the way to go: It makes your applications a lot faster and, through that, better to use.

As OpenUI5 is evolving, the loading processes in the background were significantly improved. To get the best out of these changes in the core and to speed up your app, we recommend that you switch on asynchronous loading. With asynchronous loading, files are retrieved in parallel. This is much quicker than with synchronous loading, where files are retrieved sequentially. There are a few possibilities to do that:

Use a Bootstrapping Tag in HTML Files

Add the bootstrapping tag `data-sap-ui-async="true"` to your `index.html` file. This loads the modules for all declared libraries asynchronously. If you have other HTML files in your app, you should do this there as well.

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8">
    <title>My App</title>
    <script
        id="sap-ui-bootstrap"
        ...
        data-sap-ui-async="true">
    </script>
...
```

- Learn how: Walkthrough Tutorial Step 2: Bootstrap [page 72]

- Find out more: Bootstrapping: Loading and Initializing [page 692]

Add the `async` Property to the `manifest.json`

To also load all application-specific configuration settings asynchronously, set the `async` property in the metadata of the `manifest.json` file to `true`.

```
"sap.ui5": {
        "rootView": {
            "viewName": "sap.ui.demo.worklist.view.App",
            "type": "XML",
            "async": true,
            "id": "app"
        },
```

- Learn how: Walkthrough Tutorial Step 10: Descriptor for Applications [page 91]
- Find out more: Descriptor for Applications, Components, and Libraries [page 734]

Is Your Application Ready for Asynchronous Loading?

Find a collection of information that helps you to find out if your application is ready for asynchronous loading.

Applications benefit from the configuration of the SAPUI5 module loader to work asynchronously. However, if an application or library is not yet fully compatible with asynchronous loading, you may encounter issues. To avoid running into these issues, the following list provides information that helps you to find out whether your application needs to be adapted to enable asynchronous loading. The list is not exhaustive, but points to additional information and should give you a good start in getting your applications ready for asynchronous loading.

- For asynchronous loading, your application modules have to facilitate the concept for defining and handling of modules in SAPUI5 that is aligned with the asynchronous module definition (AMD) standard. For an overview, see Best Practices for Loading Modules [page 1100].
- Existing applications may still use synchronous variants of factory methods. To make your application ready for asynchronous loading, you need to use asynchronous variants of factory methods instead. For information how you can replace the synchronous variants with asynchronous variants, see Legacy Factories Replacement [page 1124].
- The global access to legacy APIs triggers a compatibility layer to load such modules synchronously and needs to be replaced to enable your application for asynchronous loading. For information how you replace the global access, see Legacy jQuery.sap Replacement [page 1109].
- The Support Assistant also helps you to identify issues in your application, especially issues related to synchronous or asynchronous loading. For information about the Support Assistant, see Support Assistant [page 1339].
- If your application relies on certain points in time, you may run into runtime issues when you switch from synchronous to asynchronous module loading and the points in time on which your application relies are different due to this change. Here are two examples of such issues:
  An event gets triggered before potential listeners had the chance to attach themselves. Whereas this may have worked for synchronous loading where the timing of module loading and initializing is different, this causes issues for asynchronous loading. To resolve this and to ensure that all modules are properly loaded

and exectued, all necessary module dependencies for the module that actually triggers the event need to be handled by `sap.ui.require` or `sap.ui.define`.
A controller listens on the `EventBus` for a certain event that is triggered by another controller. Depending on the loading time of the corresponding views, the `init` controller methods may be called at a different point in time. For information how to resolve this, see Best Practices for Loading Modules [page 1100].

- Issues with asynchronous loading can also occur, if your application uses XML views that are configured to be loaded asynchronously via the `manifest` property, for example for the root view `sap.ui5/rootView/async=true`. To detect such issues, we recommend to do extensive (automatic) testing to ensure the application continues to work as expected.

Known Incompatibilities

The `sap.viz` library uses another module loader in addition to the SAPUI5 module loader in some scenarios. In combination with the `async=true` configuration parameter, this currently leads to issues and may break your application.

Performance Checklist

Follow these steps to apply performance best practices to your application.

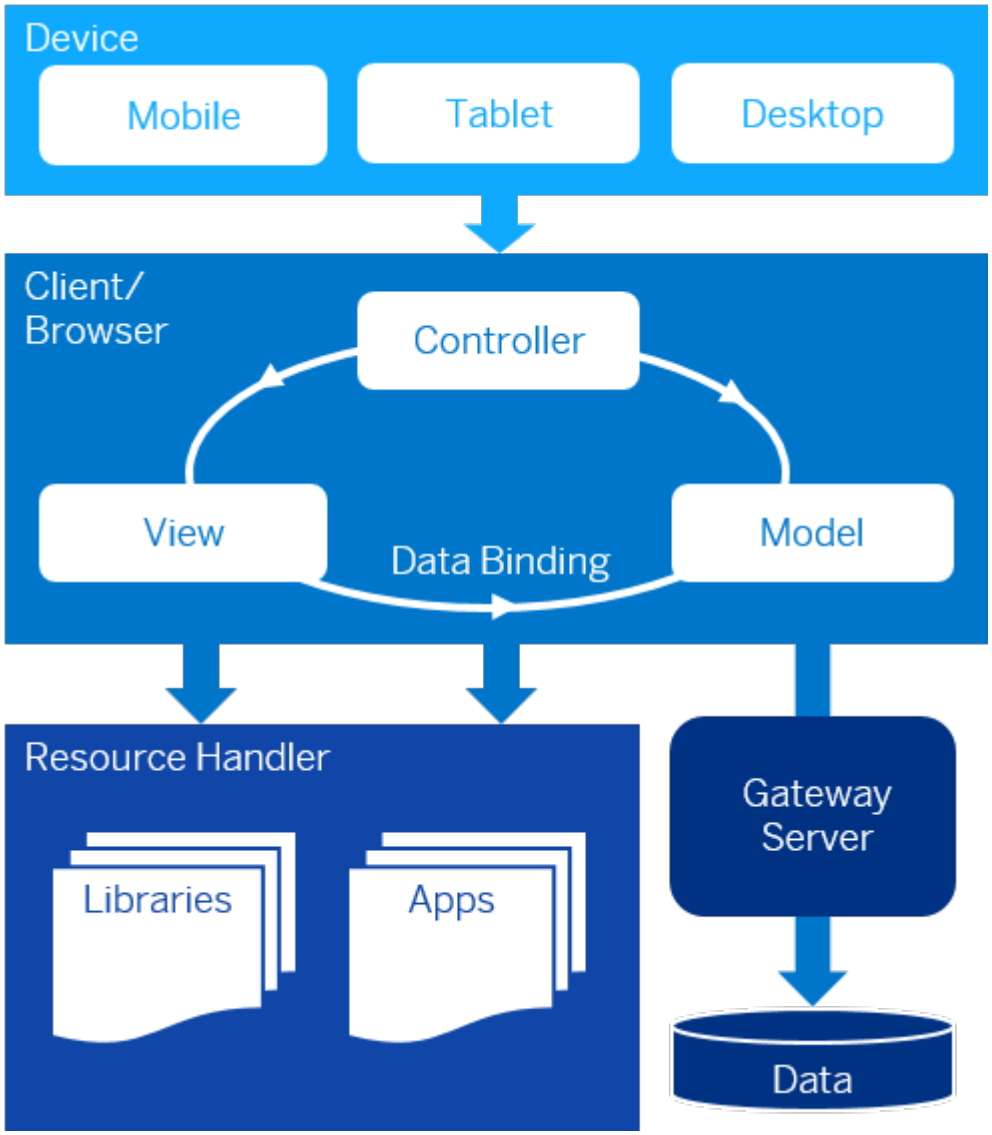
In addition to applying best practices, always stay up to date with the framework, for instance via the SAPUI5 Release Notes and the What's New in SAPUI5 [page 6].

1. Use the UI5 Support Assistant to Check for Known Issues [page 1339]
2. Enable Asynchronous Loading in the Bootstrap [page 1434]
3. Ensure the Root View and Routing are Configured to Load Targets Asynchronously [page 1435]
4. Make Use of Asynchronous Module Loading (AMD Style) [page 1436]
5. Use `manifest.json` instead of the Bootstrap to define Dependencies [page 1436]
6. Load SAPUI5 from the Content Delivery Network (CDN) [page 1437]
7. Ensure that all Resources are Available to Avoid 404 Errors [page 1438]
8. Use "manifest first" to load the Component [page 1438]
9. Ensure that Library Preloads are Enabled [page 1438]
10. Ensure that Application Resources are Loaded as Component Preload [page 1438]
11. Check Network Requests [page 1439]
12. Migrate `jquery.sap.*` Modules to their Modularised Variants [page 1439]
13. Migrate Synchronous Variants of UI5 Factories to Asynchronous Variants [page 1440]
14. Use the OData V2 Model Preload [page 1440]
15. Use OData V2 Metadata Caching [page 1440]
16. Check Lists and Tables [page 1440]
17. Further Optimize your Code [page 1441]

Essentials

This chapter and its sections describe the development concepts of SAPUI5, such as the Model View Controller, data binding, and components. Use this section as a reference.

SAPUI5 Architecture



SAPUI5 is a client UI technology based on JavaScript, CSS and HTML5.

Apps developed with SAPUI5 run in a browser on any device (mobile, tablet or desktop PC).

When users access an SAPUI5 app, a request is sent to the respective server to load the application into the browser. The view accesses the relevant libraries. Usually the model is also instantiated and business data is fetched from the database.

Depending on the environment in which SAPUI5 is used, the libraries or your applications can be stored, for example, on an SAP NetWeaver Application Server or an SAP Cloud Platform, and business data can be accessed, for example, using the OData model through a SAP Gateway.

Artifacts in the Framework

The top-level structural unit is called a **library**. Libraries are the master artifacts in the extensibility concept. They bundle a set of controls and related types and make them consumable by Web applications. There are predefined and standard libraries, like `sap.m`, with many commonly used controls. At the same time, it treats custom UI libraries as first-class citizens, making it easy for you to write and use your own controls alongside the predefined ones.

A UI **element** is the basic building block of our user interfaces; it is a reusable entity with properties, events, methods, and relations. The most important relations are aggregations to other UI elements, and in this way a tree structure of elements can be created.

From a developer's point of view, a **control** (e.g. `Button`, `Label`, `TextField`, or `Table`) is the most important artifact. It is an object which controls the appearance and user interaction of a rectangular screen region. It is a special kind of user interface element which can be used as the root of such a tree structure. In this way, it serves as an entry point, especially for rendering. Besides controls, there are also other **non-control elements**, which cannot be used as the root of such a tree structure, but only as a dependent part within it (e.g. `TableRow`, `TableCell`).

Data types are first-class entities in the meta model. This allows reuse of types across libraries and extensibility of the type system. The core library (technically, this is the `sap.ui.core` library) already defines a core set of types that can be used in other libraries.

Bootstrapping: Loading and Initializing

To use SAPUI5 features in your HTML page, you have to load and initialize the SAPUI5 library.

You can use the SAPUI5 bootstrap script in your page to initialize SAPUI5 runtime automatically as soon as the script is loaded and executed by the browser. For simple use cases as well as the default SAPUI5 installation, this is sufficient to build and run UIs. In addition to this, you can specify the set of SAPUI5 libraries and the theme used for your application in the configuration settings.

> **i** Note
>
> If you run your app standalone, the bootstrap is added to your HTML page. In an SAP Fiori launchpad environment, the launchpad executes the bootstrap and no additional HTML page is needed to display the app.

The following code snippet shows a typical bootstrap script tag:

```
<script id="sap-ui-bootstrap"
     type="text/javascript"
     src="resources/sap-ui-core.js"
     data-sap-ui-theme="sap_belize"
     data-sap-ui-libs="sap.m"
```

```
      data-sap-ui-compatVersion="edge">
</script>
```

The attributes `data-sap-ui-theme="sap_belize"` and `data-sap-ui-libs="sap.m"` already provide examples of how SAPUI5 runtime can be configured to the needs of an application.

Overview of Bootstrap Files

SAPUI5 provides several bootstrap files for different use cases. The following table gives an overview of the most important resources and the respective use cases. The resource names refer to the `resources/` folder in the SAPUI5 installation. The actual base URL depends on your platform and administrative setup.

Resource	Description
`sap-ui-core.js`	This is the standard bootstrap file, which we recommend to use for typical use cases. It already contains jQuery, `jquery-ui-position` and only the minimum required parts of the core library (`sap.ui.core`). Required files are loaded dynamically using XMLHttpRequest (XHR). For more information, see Standard Variant for Bootstrapping [page 694].
Content Delivery Network (CDN)	You can access the libraries externally from a CDN. For more information see Variant for Bootstrapping from Content Delivery Network [page 696].
`sap-ui-core-nojQuery.js`	You use this bootstrap file for applications with their own jQuery version. It also contains the minimum required parts of the core library, but **not** jQuery and `jquery-ui-position`. For more information, see noJQuery Variant for Bootstrapping [page 698].
`sap/ui/core/library-preload.js`	This file contains most of the modules that are contained in the `sap.ui.core` library, but the modules are parsed and executed only on demand, and not immediately. ⚠ Caution An application must not reference this file. If the configuration option is set to `preload`, SAPUI5 automatically loads the file. For more information, see Standard Variant for Bootstrapping [page 694].
`sap-ui-core-lean.js`	This bootstrap file is similar to the `sap-ui-core.js` file, but in this use case only the jQuery and one SAPUI5 file are

Resource	Description
	loaded immediately and the other files are loaded dynamically. **⚠ Caution** This use case is usually **not** used and may be removed in future.
`sap-ui-custom*.js`	File names that match this pattern are reserved for custom merged files used by the application. **i Note** The proposed naming scheme for these files needs to be adapted in future versions for the same encapsulation reasons as mentioned above.

Standard Variant for Bootstrapping

The standard variant for bootstrapping loads all JavaScript modules of a library in advance with one single request for performance reasons.

The library preload file `library-preload.js` contains all modules of a certain library. These modules will only be executed on demand, if the application requires them. Using preloads significantly reduces the number of roundtrips since the single modules are bundled in one file.

> **i Note**
>
> An application must **not** reference the `library-preload.js`. If preload files exist, SAPUI5 automatically loads them. The dependencies to libraries are defined as part of the manifest namespace `sap.ui5/dependencies/libs`. For further information, see Descriptor for Applications, Components, and Libraries [page 734].

Option 1 (Recommended)

By setting the `async=true` configuration parameter, the module loader loads the modules and preload files asynchronously. You can enable it in an existing application by specifying the `sap-ui-async` configuration parameter in the start URL, or by adding the `data-sap-ui-async` attribute to the bootstrap tag:

```
<script
    id="sap-ui-bootstrap"
    src="resources/sap-ui-core.js"
    data-sap-ui-theme="sap_belize"
    data-sap-ui-async="true"
    data-sap-ui-onInit="module:my/app/main"
```

```
    data-sap-ui-resourceRoots='{"my.app": "./"}'
></script>
```

> **i Note**
>
> Before you use the `async` configuration parameter, make sure your app is ready for asynchronous loading, see Best Practices for Loading Modules [page 1100] and Is Your Application Ready for Asynchronous Loading? [page 689].

Option 2

Alternatively, you can influence the loading behavior of the preload files without affecting other single modules by setting the `preload` configuration parameter to one of the following values:

- `async` (recommended)
  If you set the `preload` configuration option to `async`, the runtime loads the modules for all declared libraries asynchronously. Thus, for any code that follows the SAPUI5 bootstrap tag, the framework cannot make sure that the classes are already available. Therefore, the application must delay the access to the SAPUI5 APIs by using the `Core.attachInitEvent` method. SAPUI5 supports the `async` mode only for libraries that are loaded by the SAPUI5 core. Libraries that are loaded dynamically by using the `sap.ui.getCore().loadLibrary()` API will be loaded synchronously by default for compatibility reasons. Only when a configuration object with a property of `async:true` is passed, the bundle is loaded asynchronously.
- `sync`
  If you set the `preload` configuration parameter to `sync`, the runtime loads the modules for all declared libraries synchronously. After processing the bootstrap tag, all preload files of all libraries are loaded and the libraries are initialized as usual. The `preload=sync` mode should be transparent for most applications.
- `auto`
  The `preload=auto` configuration parameter is the default value. This mode checks whether SAPUI5 runtime uses optimized sources. If optimized sources are used, it enables the `preload=sync` option to further optimize the runtime. For normal or debug sources, the preload is deactivated.

You can easily check this with an existing application by specifying the `sap-ui-preload=<mode>` parameter in the start URL or by adding the `data-sap-ui-preload` attribute to the bootstrap tag:

```
<script
    id="sap-ui-bootstrap"
    src="resources/sap-ui-core.js"
    data-sap-ui-theme="sap_belize"
    data-sap-ui-preload="async"
    data-sap-ui-onInit="module:my/app/main"
    data-sap-ui-resourceRoots='{"my.app": "./"}'
></script>
```

> **i Note**
>
> Using the `async=true` or `preload=async` configuration parameters requires extensive testing and cooperation on application side to ensure a stable and fully working application. It is, therefore, not activated automatically, but only by configuration. If you encounter issues, or if you want to prepare your application in advance, see Is Your Application Ready for Asynchronous Loading? [page 689].

> **i Note**
>
> Preload sources are always optimized. However, using the `debug=true` configuration parameter always disables the loading of preload files.

> **i Note**
>
> You can combine the `async` or `preload` configuration parameters with other bootstrap variants such as `sap-ui-core-noJQuery`.

Configuration of the SAPUI5 Runtime [page 699]
Is Your Application Ready for Asynchronous Loading? [page 689]

Variant for Bootstrapping from Content Delivery Network

SAPUI5 can either be loaded locally with a relative path from an SAP Web server or externally from a Content Delivery Network (CDN).

> **i Note**
>
> Loading SAPUI5 from a CDN improves your app performance: You can load from a server that (in most cases) is much closer to your location, and you can benefit from the caching mechanism and the language fallback logic.

Bootstrapping From SAPUI5 CDN

SAPUI5 application hosted on SAP Cloud Platform are allowed to leverage the SAPUI5 CDN to retrieve the SAPUI5 distribution layer artifacts.

Specific Version

Check the available versions with the respective maintenance status at https://ui5.sap.com/versionoverview.html.

You can refer to a specific version by using a versioned URL as in the following example:

```
<script id="sap-ui-bootstrap"
    type="text/javascript"
    src="https://sapui5.hana.ondemand.com/1.42.6/resources/sap-ui-core.js"
    data-sap-ui-theme="sap_belize"
    data-sap-ui-libs="sap.m"></script>
```

The first segment of the URL after the host name is used to specify a concrete version.

Default Version

The default version of our libraries has the generic URL https://sapui5.hana.ondemand.com/resources/sap-ui-core.js (SAPUI5).

> ⚠ Caution
>
> The default version is constantly being upgraded and this might have an impact on the stability of your application. Use this version for testing purposes only.
>
> If you want to use the default version, you can use the following bootstrap scripts:

```
<script id="sap-ui-bootstrap"
    type="text/javascript"
    src="https://sapui5.hana.ondemand.com/resources/sap-ui-core.js"
    data-sap-ui-theme="sap_belize"
    data-sap-ui-libs="sap.m"></script>
```

Cache Control

The cache control is different for dynamic and static resources. If you refer to the latest maintenance version (dynamic), you have a maximum cache age of one week, if you refer to a specific (static) version, you have a maximum cache age of 10 years. In both cases, cross-origin resource sharing (CORS) headers are set, so that you can consume resources from the central location without any proxy in between.

> ℹ Note
>
> The Cache Buster is only needed if you consume SAPUI5 without a concrete version in the URL. When you consume SAPUI5 with the concrete version in the URL, this is not needed, as the content served by that unique URLs will never change and can be cached forever.

Bootstrapping from Custom CDN

SAPUI5 applications hosted on platforms other than SAP Cloud Platform can leverage a custom CDN to retrieve the SAPUI5 distribution layer artifacts. For this, the SAPUI5 distribution layer artifacts must be deployed on an SAP web server.

To use your custom CDN with the SAPUI5 ABAP repository, you need to configure this CDN as an external location in the customizing. For more information, see the documentation for the Customizing activity *Configure SAPUI5 Bootstrapping* in Customizing under *SAP NetWeaver* > *UI Technologies* > *SAPUI5*.

Multi-Version Availability of SAPUI5

Versioning of SAPUI5 [page 29]

noJQuery Variant for Bootstrapping

The noJQuery variant supports bootstrapping for an application that already integrates jQuery or uses a different jQuery version than SAPUI5.

In this variant, you include the `resources/sap-ui-core-noJQuery.js` file in your HTML page. Make sure that jQuery and `jquery-ui-position` have been loaded beforehand. The following code snippet shows an example:

```
    <!-- include some jQuery version -->
    <script src="my-jQuery-min.js" ></script>
    <!-- application does not have its own jquery-ui-position, so it might use
the one from SAPUI5 -->
    <script src="resources/sap/ui/thirdparty/jqueryui/jquery-ui-position.js" ></
script>
    <!-- now booting SAPUI5 -->
    <script
            id="sap-ui-bootstrap"
            src="resources/sap-ui-core-nojQuery.js"
            data-sap-ui-libs="sap.m"
            data-sap-ui-theme="sap_belize" >
    </script>
```

Initialization Process

The initialization process starts after SAPUI5 runtime is loaded.

The initialization of the SAPUI5 runtime comprises the following steps:

1. The jQuery plugins, which are mainly located in the `jQuery.sap` namespace, provide fundamental functionality of SAPUI5, such as the modularization concept, a logging framework, performance measurement, and so on.
2. The global object `sap` is defined.
3. The `sap.ui.core.Core` class is executed with all its dependencies.
4. The runtime configuration is determined from different sources.
5. All libraries and modules declared in the configuration as well as their dependencies are loaded.
6. For each loaded library, the CSS file of the configured theme is loaded.
7. When all libraries are loaded and the document is ready, the `initEvent` of the core is fired and all registered handlers are executed.

Initialization Readiness

The optimal point in time to execute or start an application is after the framework has been initialized. You can use the `attachInit` function to determine this point in time: The callback of the `attachInit` function is executed directly after the framework has been initialized.

```
sap.ui.getCore().attachInit(function(){
    // application can be started
});
```

As an alternative, you can also use a bootstrap module, see Standard Variant for Bootstrapping [page 694].

Loading of Additional Resources During Bootstrap

The SAPUI5 runtime loads and interprets additional resources for the control libraries during bootstrap.

The files are loaded in the following sequence:

1. Library bootstrap file `/<context-path>/resources/<library-name>/library.js`
   A JavaScript file that contains the JavaScript code for all enumeration types provided by the library as well as library-specific initialization code that is independent from the controls in the library. The file calls the `sap.ui.getCore().initLibrary` method with an object that describes the content of the library (list of contained controls, elements etc.). For libraries that have been developed with SAPUI5 application development tools or the SAPUI5 offline build tools, this file is generated automatically during the build
2. Library style sheet file `/<context-path>/resources/<library-name>/themes/<theme-name>/library.css`
   SAPUI5A standard CSS file that contains all styles relevant for this library. For application development tools, this file is generated automatically during the build.

Dynamic Loading of Libraries

SAPUI5 provides the `sap.ui.getCore().loadLibary()` method to load libraries at runtime in addition to the libraries declared in the runtime configuration.

After loading, you can use all controls from the library. For these additional libraries, the same restriction apply as for the declared libraries: Accessing the document object model (DOM) is only possible after the `document.ready` event of the HTML page. Also, rendering applies for these libraries in the same way as for the declared libraries.

Configuration of the SAPUI5 Runtime

SAPUI5 provides several options for the configuration of the SAPUI5 runtime, such as runtime default values and script tag attributes.

When the SAPUI5 bootstrap script is included in a page, the SAPUI5 runtime will automatically be initialized as soon as the script is loaded and executed by the browser. For simple use cases and for a default SAPUI5 installation, this should already be sufficient to build and run UIs. The only additional information that usually is specified, is the set of libraries and the theme that is used.

So a typical bootstrap script looks like this:

```
<script id="sap-ui-bootstrap"
            type="text/javascript"
            src="resources/sap-ui-core.js"
            data-sap-ui-theme="sap_belize"
            data-sap-ui-libs="sap.m"
            data-sap-ui-compatVersion="edge">
```

```
</script>
```

For more information see Bootstrapping: Loading and Initializing [page 692].

You can use the following ways to provide configuration information.

Default Values

The easiest way to specify a configuration value is **not to specify** it. The SAPUI5 runtime contains a default value for each configuration option. As long as you don't have to change the value, you don't specify it.

Individual Script Tag Attributes

For each configuration option, you can have one attribute in the bootstrap script tag.

The attributes have to provide the following information:

- Attribute name
  The attribute name is composed of the name of the configuration option and the `data-sap-ui-` prefix. The first part of the prefix (`data-`) is necessary to comply with the W3C recommendations for custom attributes in HTML. The second part (`-sap-ui-`) separates SAPUI5 attributes from custom attributes defined by any other framework.

  > **i Note**
  >
  > Attribute names in HTML are case-insensitive and this also applies to the configuration attribute names. However, SAPUI5 has defined some configuration options names in camel case, for example `originInfo`. SAPUI5 converts these names automatically to lower case when accessing the configuration.

- Value
  Element attributes in HTML have a `string` value by definition. For configuration options of type `string`, the attribute value is equivalent to the value of the option.

  > **i Note**
  >
  > If the value contains specific HTML characters, such as '<' or '>', or if the value contains the same quote character that is used to wrap the attribute value, the usual HTML escape mechanisms must be used: Use entities for the specific HTML characters, for example `<` instead of `<`, and switch the type of quotes from single to double or vice versa.

  For configuration options that are **not** of type `string`, the format of the allowed values has to be defined as follows:

Type	Notation/Values
`string`	String; escaped according to the HTML conventions

Type	Notation/Values
`boolean`	`true` and `x` are both accepted as true values (case-insensitive), all others are false. We recommend to use `false` for false values
`int`	Any integer value
`string array`	Comma-separated list of values; comma is not supported in the values (no escaping)
map from string to string	JavaScript object literal (preferably JSON syntax)

Single and Complex Configuration Attributes

The attribute `data-sap-ui-config` makes it possible to provide a single attribute with the configuration information for the SAPUI5 runtime.

You can use this attribute instead of attaching individual options with individual configuration attributes to the script tag. Its content is similar to the global configuration object, but without the enclosing parenthesis: It is a comma separated list of key-value pairs.

> **i** Note
>
> The usual HTML escape mechanisms must be used if the value contains specific HTML characters (<, >, &) or the quote character that is used to enclose the attribute value.

```
<script id="sap-ui-bootstrap"
    type="text/javascript"
    src="resources/sap-ui-core.js"
    data-sap-ui-config="theme:'sap_belize',
    libs:'sap.m'"
    >
</script>
```

Global Configuration Objects

The global configuration object is a property in the global `window` object with property name `sap-ui-config`. The property must be a simple object, where each property represents the configuration option of the corresponding name.

To avoid conflicts with typical JavaScript coding, the name of the `window` property is not a valid JavaScript identifier. The name structure is chosen to avoid conflicts with SAP objects. To define the object, quotes must be used. If a configuration option has a name that is not a valid JavaScript identifier or that is a reserved token in JavaScript, the property name in the configuration object must be quoted. Currently, such a configuration option does **not** exist.

As the configuration is evaluated during bootstrap, the configuration object must be created **before** SAPUI5 is bootstrapped. Otherwise, the contained configuration cannot be evaluated. As a consequence, using the global configuration object requires another script tag in front of the bootstrap script tag. It is up to the application

whether it uses an inline script tag or a separate JavaScript file, which is loaded via a script tag, for this purpose. If you use a dedicated file, it may require more work initially, but offers the following advantages:

- Several pages can share the file and, thus, use the same configuration.
- The Content Security Policy (CSP) mechanism as introduced, for example, by Firefox 4.0 and others requires the use of a file.

The following code snippet shows an example for an inline script tag:

```
<script type="text/javascript">
            window["sap-ui-config"] = {
            theme : "sap_belize",
            libs : "sap.m",
            };
</script>
<script id="sap-ui-bootstrap"
            src="resources/sap-ui-core.js"
        >
</script>
```

This option requires an additional script or script tag, but it offers the following advantages:

- Possibility to share configuration between pages
- Can be used in environments where the scrip tag cannot be influenced, for example, because it is created out of some configuration, like in some mashup frameworks
- Allows to provide configuration before the core boots

URL Parameters

Configuration parameters can be added to the URL of an app.

The URL parameter name is composed of the name of the configuration option and the `sap-ui-` prefix, for example like `index.html?sap-ui-debug=true`.

> **i Note**
>
> The W3C proposed that the `data-` prefix is not needed and not even allowed here as all URL parameters are kind of custom parameters.

The value of a URL parameter is of type `string` and the same type mapping as for HTML attributes applies. However, URLs require a different encoding than HTML; they use, for example % encoding instead of entity encoding.

For security reasons, only some configuration options can be set via URL parameters. An application can set the `ignoreUrlParameters` option to `true` to disable URL configuration parameters completely.

Runtime Configuration Object

The runtime configuration object enables you to modify a limited set of configuration options at runtime.

The configuration options above are evaluated during the SAPUI5 runtime boots. After that, all changes to these parameters are ignored. To read the final configuration result, you can use the `sap.ui.getCore().getConfiguration()` method.

The same object also provides set methods for a very limited set of configuration options that can be modified at runtime. The runtime and/or the controls can react on these configuration changes. The most prominent (and so far only) example for such a configuration option is the theme.

Order of Significance

1. Attributes of the DOM reference override the system defaults.
2. URL parameters override the DOM attributes; empty URL parameters reset the parameter to its system default.
3. If you call setters at runtime, any previous settings calculated during object creation are overwritten with the new value.

Configuration Options and URL Parameters

The complete list of configuration options available in SAPUI5 can be found in the *API Reference* under `sap.ui.core.Configuration`. The following table shows a subset of the available configuration options.

> **i** Note
>
> A subset of these configuration parameters can also be used as URL parameter ("URL: Yes"). The URL parameter name is composed of the name of the configuration option and the `sap-ui-` prefix, for example like `sap-ui-debug=true`.

Option	Type
`accessibility`	Type: `boolean` Default value: `true` URL: Yes Modifiable at runtime: No If set to `true`, the SAPUI5 controls are rendered for or running in accessibility mode.
`animationMode`	Type: `string` Default value: `full` URL: Yes Modifiable at runtime: Yes The following animation modes are available:

Option	Type
	• `full`: all animations are shown • `basic`: a reduced, more light-weight set of animations • `minimal`: no animations are shown, except animations of fundamental functionality • `none`: deactivates the animation completely This parameter replaces the deprecated Boolean `animation` parameter. For all controls that implement the `animation` parameter, the `animationMode` is set as follows: • If `animation` is set to `true`, this is interpreted as `animationMode full` • If `animation` is set to `false`, this is interpreted as `animationMode minimal`
`appCacheBuster`	Type: `true | string[]` Default value: [] URL: Yes Modifiable at runtime: Yes, with `AppCacheBuster` API (see Application Cache Buster: Enhanced Concept [page 1136]) If set to a non empty list of URLs, the `AppCacheBuster` will be activated and will load component version info files from the configured set of URLs (see Application Cache Buster [page 1134]).
`areas`	Type: `string[]` Default value: `null` URL: No This configuration parameter defines UI areas that shall be created in advance; use to create new UI areas and `sap.ui.getCore().getUIArea(id).destroy()` to delete existing UI areas at runtime.
`autoAriaBodyRole`	Type: `boolean` Default value: `true` URL: No Modifiable at runtime: No Determines whether the framework automatically adds the ARIA role `application` to the HTML body.

Option	Type
`bindingSyntax`	Type: `string` Default value: • As of SAPUI5 1.28, in combination with `data-sap-ui-compatVersion="edge"`: `complex` • `default` The meaning of the default value `'default'` depends on the compatibility version `sapCoreBindingSyntax`. If the compatibility version is at least 1.28, the 'complex' binding syntax is assumed, otherwise the 'simple' binding type. In other words: applications that configured a general compatibility version of 1.28 (or higher or 'edge'), will automatically run with the 'complex' binding syntax. URL: No Modifiable at runtime: No This configuration parameter defines whether the simple or the complex binding syntax is used. The parameter only affects bindings that are defined as strings, for example in the constructor of a control, or when specifying a binding in a declarative view, such as XML view or HTML view.
`calendarType`	Type: `gregorian | islamic | japanese | persian` (case-sentitive) Default value: If there is no value defined, the actual value is determined from the locale data for the configured locale. URL: Yes Modifiable at runtime: See API Reference: `sap.ui.core.Configuration.setCalendarType`. Defines the calendar type that is used for locale-dependent, date-related features (for example, formatting or parsing date and time).
`debug`	Type: `boolean` or `string` Default value: `false` URL: Yes Modifiable at runtime: No If set to `true`, the debug sources are loaded; if the bootstrap code is loaded from an optimized source, the

Option	Type
	bootstrap will be aborted and start anew from a debug source. You can also specify a comma-separated list as `string` that contains all modules that should be loaded as debug source. Example: `index.html?sap-ui-debug=sap/ui/model/odata/v2/` will load all debug sources for all modules of the OData V2 model. All others modules will be taken from the preload (if preload is active). You can use the following patterns: • A trailing slash (`/`) means that the complete package should be included (shortcut for `/**/*`) Example: `sap/ui/model/odata/v2/` loads everything from the `sap/ui/model/odata/v2/` package as debug source (also nested packages `sap/ui/model/odata/v2/**/*`). • `**/` matches any package or sequence of packages Example: `**/v2/` loads any package named `v2` as debug sources like `odata/v2`, `json/v2/` etc. • `*` matches any part of a simple name Example: `sap/ui/model/*` matches all files directly contained in the model package, but not in nested packages (for example, not `v2` or `v4`) **i Note** You can also select the debug sources in the technical information dialog. For more information, see Technical Information Dialog [page 1322].
`formatLocale`	Type: `string` Default value: `undefined` URL: Yes Modifiable at runtime: No This configuration parameter defines the locale used for formatting purposes; the default values for the locale are derived from the language.
`frameOptions`	Type: `string` Default value: `default` URL: No

Option	Type
	Modifiable at runtime: No Frame options mode; for more information, see Frame Options [page 1478]
`frameOptionsConfig`	Type: `object` Default value: undefined URL: No Modifiable at runtime: No Advanced frame options configuration; for more information, see Frame Options [page 1478]
`ignoreUrlParams`	Type: `boolean` Default value: `false` URL: No Modifiable at runtime: No Security-relevant parameter that allows applications to disable configuration modifications via URL parameters.
`inspect`	Type: `boolean` Default value: `false` URL: Yes Modifiable at runtime: No If set to `true`, the `sap-ui-debug.js` module is included and provides some supportability features
`language`	Type: `string` Default value: `user language` URL: Yes Modifiable at runtime: Yes, with restrictions. This configuration parameter defines the language that shall be used for localized texts, formatting, and so on. For more information, see API Reference: `sap.ui.core.Configuration.setLanguage` and Identifying the Language Code / Locale [page 1269].
`libs`	Type: `string[]` Default value: `[ ]` URL: No

Option	Type
	Modifiable at runtime: Yes This configuration parameter defines a list of libraries that shall be loaded initially; use the `loadLibrary()` method to load further libraries. For more information, see: loadLibrary
`logLevel`	Type: `0 | 1 | 2 | 3 | 4 | 5 | 6 | NONE | FATAL | ERROR | WARNING | INFO | DEBUG | ALL` Default value: `ERROR` URL: Yes Modifiable at runtime: Yes This configuration parameter sets the log level to the given value; for minified (productive) sources, the default level is `ERROR`, for debug sources it is `DEBUG`. At runtime, you can modify the log level by using the `sap/base/Log.setLevel` method.
`manifestFirst`	Type: `boolean` Default value: `false` URL: Yes Modifiable at runtime: Yes, by using option with same name in the `sap.ui.component` API If set to `true`, the descriptor for a component is read and evaluated first, before loading the component code (`Component.js`).
`modules`	Type: `string[]` Default value: `[ ]` URL: No This configuration parameter defines a list of JavaScript modules that shall be loaded after the core has been initialized.
`noConflict`	Type: `boolean` Default value: `false` URL: No Modifiable at runtime: No

Option	Type
	If set to `true`, SAPUI5 forces jQuery into `noConflict` mode.
`noDuplicateIds`	Type: `boolean` Default value: `true` URL: Yes Modifiable at runtime: No If set to `true`, this configuration parameter enforces that the same IDs are **not** used for multiple controls; we highly recommend this check as duplicate IDs may cause unforeseeable issues and side effects.
`onInit`	Type: `code` or `string` Default value: `undefined` URL: No Modifiable at runtime: No This configuration setting defines code that has to be executed after the initialization. The use of this parameter with string value as (like `"myinitfunction();"`) code is no longer recommended as it requires `eval` and therefore might conflict with stronger content security policies. Either use it only in the form `window["sap-ui-config"].onInit = function() { ... }` or use the runtime API `sap.ui.getCore().attachInit()` instead. If you define a `string`, this can be a reference to a function or a name of a module. Functions are resolved from the global namespace (like `"myapp.initFunction"`). Modules are indicated by the prefix `module:` (like `"module:myapp/main/Module")`. The module will be loaded and executed after the initialization.
`originInfo`	Type: `boolean` Default value: `false` URL: Yes Modifiable at runtime: No If set to `true`, additional information for text resources is provided that allows to determine the origin of a translated text on the UI

Option	Type
`preload`	Type: not specified, `auto`, `sync`, or `async` Default value: `auto` URL: No Modifiable at runtime: No This configuration parameter defines the loading behaviour of the so-called preload files. They contain all modules of a library. The contained modules are only loaded, but not executed until they are used by the application. The values are used as follows: • When set to `auto`, SAPUI5 runtime automatically uses `preload=sync` when the `async` bootstrap configuration parameter is set to false (`async=false`) or not set at all. The `preload` files are loaded asynchronously in case `async=true` is set. • When set to `sync`, the preload files for the declared libraries are loaded synchronously. • When set to `async`, the preload files are loaded asynchronously. However, we recommend to use the `async=true` configuration parameter in the bootstrap instead, because it switches more module/ related APIs to `async` including the loading behaviour of the preload files. • For any other value (for example blank), the preload feature is deactivated and modules are loaded on demand.
`async`	Type: `boolean` Default value: `false` URL: Yes Modifiable at runtime: No This configuration setting enables the module loader to load both, modules and library-preload files asynchronously. Activating this feature requires intensive testing and cooperation on application side to ensure a stable and fully working application. In case you encounter issues, or if you want to prepare your application in advance, see Is Your Application Ready for Asynchronous Loading? [page 689].
`preloadLibCss`	Type: `string[]` Default value: `[]`

Option	Type
	URL: Yes Modifiable at runtime: No This configuration setting specifies a list of UI libraries using the same syntax as the `libs` property, for which the SAPUI5 core does not include the `library.css` stylesheet in the head of the page. If the list starts with an exclamation mark (!), no stylesheet is loaded at all for the specified libs. In this case, it is assumed that the application takes care of loading CSS, for example, a manually merged, single CSS file. Otherwise, the Core instructs the backend to create a merged CSS for the specified libs. In both cases, if the first libraries name is an asterisk (*), it will be expanded to the list of already configured libraries. **i Note** The `merge` feature is currently only available for Java and only for apps that include the additional backend component `resource-ext`. Without the merge, applications can include their own merged CSS file and suppress the loading of the standard `library.css`.
`resourceRoots`	Type: `object` Default value: undefined URL: No Modifiable at runtime: With `sap.ui.loader.config({paths: ...})`, a map can be used to define locations for resources, see `sap.ui.loader` in the API reference. To provide a URL location that is **not** overwritten by a component later on, `final` can be set to `true`, for example: `{'url' : '/that/is/the/prefix/', 'final' : true}` For more information, see jQuery.sap.registerModulePath
`rtl`	Type: `boolean` Default value: `false` URL: Yes Modifiable at runtime: Yes, with restrictions. For more information, see API Reference: `sap.ui.core.Configuration.setLanguage` and

Option	Type
	API Reference: `sap.ui.core.Configuration.setRTL`. If set to `true`, all controls are rendered in right-to-left (RTL) mode; not yet determined automatically.
`statistics`	Type: `boolean` Default value: `false` URL: Yes Modifiable at runtime: No Activates end-to-end traces and measurement of response times For more information, see Interaction Tracking for Performance Measurement [page 1382]
`theme`	Type: `string` Default value: `base` URL: Yes Modifiable at runtime: Yes This configuration parameter defines the theme that shall be used for the current page; you can change the theme at runtime by calling `sap.ui.getCore().applyTheme()`. **Theme Root:** When the theme string contains an at-sign (`@`), anything before the `@` is assumed to denote the ID of the theme while anything after the `@` is assumed to represent the URL location of the theme. To defend against XSS attacks, only tthe server-relative part of the URL is used, any host or port prefix will be ignored.
`themeRoots`	Type: `object` Default value: undefined URL: No Modifiable at runtime: `sap.ui.getCore().setThemeRoot()` This configuration parameter defines the location of themes.
`trace`	Type: `boolean` Default value: `false`

Option	Type
	URL: No Modifiable at runtime: No If set to `true`, this configuration parameter activates an overlay div that contains a trace.
`trailingCurrencyCode`	Type: `boolean` Default value: `true` URL: Yes Modifiable at runtime: No By default the currency codes are shown after the amount. If set to `false`, the currency code will be shown as configured by the locale-specific patterns of the Common Locale Data Repository (CLDR).
`uidPrefix`	Type: `string` Default value: '--' URL: No Modifiable at runtime: No Prefix to be used for automatically generated control IDs; must be chosen carefully to avoid conflicts with IDs defined by the application or DOM IDs.
`versionedLibCss`	Type: `boolean` Default value: `false` URL: Yes Modifiable at runtime: No If set to `true`, the version parameters are included in requests to the library theme resource (for example, the parameter `library.css?version=1.0.1&sap-ui-dist-version=1.0.2` is added. `version` contains the library version and `sap-ui-dist-version` the version of the SAPUI5 distribution . This applies to the following resources: • `library(-RTL).css` (or any other variation) • `library-parameters.json` URLs within the CSS or parameters are not modified.
`weinreId`	Type: `string`

Option	Type
	Default value: URL: Yes Modifiable at runtime: No
`weinreServer`	Type: `string` Default value: URL: No Modifiable at runtime: No URL to a WEINRE server to be used for debugging purposes; if set, SAPUI5 automatically includes the WEINRE target modules.
`whitelistService`	Type: `string` Default value: URL: No Modifiable at runtime: No URL to a whitelist service; see Whitelist Service [page 1478]

Experimental Options

The options listed in the table below are 'experimental'. They may be removed in future versions, or their definition or behavior may change in an incompatible way. Experimental options are identified by the name prefix `xx-`. Experimental configuration options are used for support scenarios where SAPUI5 development needs the freedom to evolve supportability features over time. Others are related to experimental features where the underlying feature still may change. When an experimental configuration option becomes mature, the `xx-` prefix is removed from the definition. For compatibility reasons, the old name with the `xx-` prefix will still be supported.

Option	Type
`xx-componentPreload`	**i Note** This is an experimental feature and may be modified or removed in future versions. Type: `sync | async |off` Default value: same as `preload` URL: Yes Modifiable at runtime: No

Option	Type
	Allows to suppress the preload of component resources (`Component-preload.js`). By default, the component resources are automatically preloaded when preloads are active in general (e.g. when running against the optimized SAPUI5 runtime and not running in debug mode). With this parameter, the preload can be switched off without affecting the library preload. `sync` or `async` has no meaning, both are accepted to be compatible with the library preload, but the code that creates a component decides whether this happens synchronously or asynchronously. .
`xx-debugModuleLoading`	**i Note** This is an experimental feature and may be modified or removed in future versions. Type: `boolean` Default value: `false` URL: Yes Modifiable at runtime: No When set to `true`, the SAPUI5 module loading feature produces `DEBUG` output for every required, executed, or required but already loaded module. This can help to analyse issues with dependency order, and so on.
`xx-debugRendering`	**i Note** This is an experimental feature and may be modified or removed in future versions. Type: `boolean` Default value: `false` URL: Yes Modifiable at runtime: No When set to `true`, some components of the SAPUI5 rendering system (`RenderManager`, `UIArea`) create a far more verbose debug output for rendering steps, for example: • Which controls have to be rendered? • Who invalidated the control? (stacktrace) • Was one rendering run sufficient, or have there been multiple runs?
`xx-libraryPreloadFiles`	**i Note** This is an experimental feature and may be modified or removed in future versions. Type: `string[]` Default value: `both` URL: Yes Modifiable at runtime: No

Option	Type
	Allows to enforce the use of a specific preload file type: • for all libraries: `?sap-ui-xx-libraryPreloadFiles=json` • for individual libraries (might be a comma separated list): `?sap-ui-xx-libraryPreloadFiles=sap.m:none,sap.ui.layout:json` • for a combination of both: `?sap-ui-xx-libraryPreloadFiles=both,sap.m:none,sap.ui.layout:js` Possible values for the file types are • `none` (no preload at all) • `json` (only try to load `library-preload.json`) • `js` (only try to load `library-preload.js`) • `both` (first try `js`, then `json`). Any other value will be ignored. The default is `both` for all libraries.
`xx-noless`	**i Note** This is an experimental feature and may be modified or removed in future versions. Type: `boolean` Default value: `false` URL: Yes (only!) Modifiable at runtime: No Only useful at development time: when set to `true`, the browser-based compilation of LESS theming files is suppressed, only the CSS that is created at built-time will be loaded.
`xx-nosync`	**i Note** This is an experimental feature and may be modified or removed in future versions. Type: `boolean` | `warn` Default value: `false` URL: Yes Modifiable at runtime: No When set to `warn`, any use of synchronous XHRs will be reported with a warning in the console. When set to `true`, such calls will cause an error.
`xx-showLoadErrors`	**i Note** This is an experimental feature and may be modified or removed in future versions. When executing a loaded module synchronously, some browsers do not provide a proper error location. By setting this configuration parameter to `true`, SAPUI5 can be advised to load a failed script a second time,

Option	Type
	but asynchronously with a script tag. This usually results in an easier to understand syntax error message and a code location.
`xx-supportedLanguages`	**Note** This is an experimental feature and may be modified or removed in future versions. Type: `string[]` Default value: `[]` URL: Yes Modifiable at runtime: No With this option the client can be instructed to limit its backend requests for translatable texts to the configured set of languages. An empty value or the value `*` allows any language, the value `default` limits the requests to the set of languages that are delivered with SAPUI5.
`xx-test-mobile`	**Note** This is an experimental feature and may be modified or removed in future versions. Type: `boolean` Default value: `false` Modifiable at runtime: No This configuration parameter activates support for mobile device-specific events, such as touch events. This enables you to test standard SAPUI5 controls on mobile devices.
`xx-viewCache`	**Note** This is an experimental feature and may be modified or removed in future versions. Type: `boolean` Default value: `true` URL: Yes Modifiable at runtime: No Allows to disable the view caching, for example, during development. (See XML View Cache [page 797].)
`xx-waitForTheme`	**Note** This is an experimental feature and may be modified or removed in future versions. Type: `boolean` Default value: `false` URL: Yes

Option	Type
	Modifiable at runtime: No If set to `true`, the first (initial) rendering of the application will be delayed until the theme has been loaded and applied (until `Core.isThemeApplied()`). Helps to avoid FOUC (flash of unstyled content).

Compatibility Version Information

Compatibility version flags allow applications to react to incompatible changes in SAPUI5.

> ⚠ Caution
>
> The concept of compatibility versions has been abandoned as of version 1.28. Therefore, there will be no new compatibility version flags in the future. If you start building a new application please set `data-sap-ui-compatVersion="edge"` on your SAPUI5 bootstrap tag.

As described in the compatibility rules, changes to SAPUI5 features are compatible, see Compatibility Rules [page 17]. In some cases, however, it may make sense to change the behavior of a feature, for example, to change the default values or to use an optimized implementation and these changes may lead to incompatibilities.

> ℹ Note
>
> We recommend to adapt to new feature versions as soon as possible.

The compatibility version configuration works as follows:

- A version flag is introduced if a feature change is incompatible.
- The version flag has to be defined in the SAPUI5 bootstrap tag either globally (`data-sap-ui-compatVersion` or individually for each feature (for example `data-sap-ui-compatVersion-xyz`). Example with `compatVersion "1.18"`

```
<script id="sap-ui-bootstrap"
        type="text/javascript"
        src="resources/sap-ui-core.js"
        data-sap-ui-theme="sap_belize"
        data-sap-ui-libs="sap.m"
        data-sap-ui-compatVersion="1.18"
        data-sap-ui-compatVersion-xyz="1.16"
        >
</script>
```

- If no version is defined, the default behavior of the feature applies.
- If an explicit version is specified, the behavior of the specified version is applied.
- If a version edge is specified, the newest behavior of the feature is applied.

- A fallback mechanism is implemented. The following table is an example of possible configuration options for feature "xyz":

data-sap-ui-compatVersion	data-sap-ui-compatVersion-xyz	Default feature xyz	Resulting compatibility version
--	--	1.14	1.14
1.16	--	1.14	1.16
--	1.16	1.14	1.16
1.18	1.16	1.14	1.16
edge	..	1.14	1.18

SAPUI5 supports the following compatibility version flags:

Flag	Description
`data-sap-ui-compatVersion-flexBoxPolyfill`	The `flexBoxPolyfill` for Internet Explorer 9 was deprecated in 1.16 due to functional deficiencies. When the compatibility version is 1.16 or higher, the polyfill is not active at all. Otherwise, the buggy implementation behaves as before, so that it still works in existing applications. Default value: 1.14
`data-sap-ui-compatVersion-sapMeTabContainer`	The `TabContainer` was deprecated in 1.15. When the compatibility version is 1.16 or higher, an error is logged to the console indicating that `sap.m.IconTabBar` should be used instead. Default value: 1.14
`data-sap-ui-compatVersion-sapMeProgessIndicator`	--
`data-sap-ui-compatVersion-sapMGrowingList`	--
`data-sap-ui-compatVersion-sapMListAsTable`	--
`data-sap-ui-compatVersion-sapMDialogWithPadding`	By default, the content area of `Dialog` had paddings. To make the padding consistent with other popups, the padding is removed for compatibility versions 1.16 or higher. If the padding is still needed inside the content area of `Dialog`, add the CSS style class `sapUiPopupWithPadding` to `Dialog` by calling the `addStyleClass` function. Default value: 1.14
`data-sap-ui-bindingSyntax`	This configuration parameter defines whether the simple or the complex binding syntax is used. The parameter only

Flag	Description
	affects bindings that are defined as strings, for example in the constructor of a control, or when specifying a binding in a declarative view, such as XML view or HTML view. For versions lower than 1.28, the default value is `default` which only has very limited features. As of version 1.28, the default is `complex`.

Compatibility Rules [page 17]

Structuring: Components and Descriptor

SAPUI5 provides faceless components for services that deliver data from the back end system, and UI components that extend components and add rendering functionality. The descriptor provides a central, machine-readable and easy-to-access location for storing metadata associated with an application, an application component, or a library.

Components

Components are independent and reusable parts used in SAPUI5 applications.

An application can use components from different locations from where the application is running. Thus, components can be developed by different development teams and be used in different projects. Components also support the encapsulation of closely related parts of an application into a particular component. This makes the structure of an application and its code easier to understand and to maintain.

> **i** Note
>
> Constraints due to cross-origin issues also apply to components.

SAPUI5 provides the following two types of components:

- Faceless components (class: `sap.ui.core.Component`)
  Faceless components do **not** have a user interface and are used, for example, for a service that delivers data from a back-end system.
- UI components (class: `sap.ui.core.UIComponent`)
  UI components extend components and add rendering functionality to the component. They represent a screen area or element on the user interface, for example, a button or a shell, along with the respective settings and metadata. `sap.ui.core.UIComponent` extends `sap.ui.core.Component` and adds rendering functionality to the component.

The `sap.ui.core.Component` class is the base class for UI and faceless components and provides the metadata for both types of components. To extend the functionality, components can inherit from their base class or from another component.

Components are loaded and created via the component factory function `sap.ui.component`. You can either pass the name of the component or the URL of the descriptor file (`manifest.json`) to load it via the descriptor, see Manifest First Function [page 735]. We recommend loading the component using the descriptor (if available) - it improves performance during the initial load since the loading process can be parallelized and optimized.

After loading the descriptor, the component factory can load the dependencies (SAPUI5 libraries and other dependent components) in parallel next to the component preload, and also models can be preloaded.

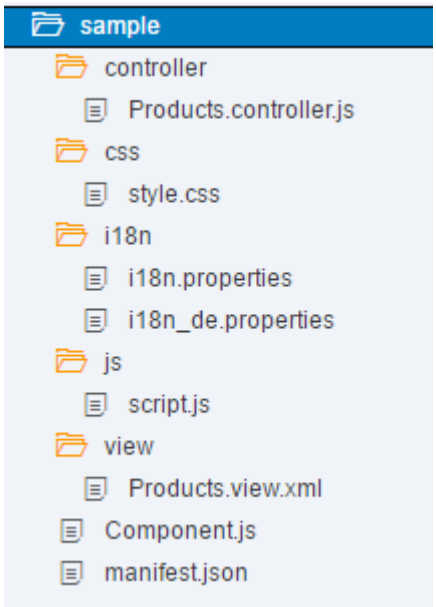
Structure of a Component

A component is organized in a unique namespace, the namespace of the component equals the component name.

Basically, a component consists of the component controller (`Component.js`) and a descriptor (`manifest.json`). Only the component controller is mandatory, but we recommend to also use the descriptor file. The descriptor then contains the component metadata, and also expresses the component dependencies and configuration (see Descriptor for Applications, Components, and Libraries [page 734]). All required and optional resources of the component have to be organized in the namespace of the component.

> **i Note**
>
> Optional resources are, for example, `CSS`, `js`, or `i18n` files, views, and controllers.

The following figure gives an example of a component folder structure.



The `ComponentContainer` control wraps a UI component. You use the `ComponentContainer` control in the SAPUI5 control tree in the same way as any other control.

Differentiation to Other Concepts in SAPUI5

The following list explains how other concepts used in SAPUI5 are distinguished from the SAPUI5 components concept:

- Composite controls
  Both concepts provide a set of controls behind a single interface. Composite controls are intended for reuse within control development and allow to include existing controls in a complex control whereas components are intended for reuse in application development.
- UI library
  The UI library is the deployable unit around controls: Controls are never deployed standalone, but as part of a control library. Components, however, are self-contained and should **not** be used to deploy controls.
- Notepad control
  A notepad control is another way to define a control. Notepad controls have all the characteristics of a control.
- MVC
  The MVC concept allows to define views and controllers and, thus, to structure and reuse parts within an application. As MVC can only be deployed separately and has no means to define dependent styles or scripts that are loaded together with a view, this concept is of limited use across different applications.

Related Information

Descriptor for Applications, Components, and Libraries [page 734]
API Reference: `sap.ui.core.Component`

Component.js File

The `Component.js` file is the component controller and provides the runtime metadata and the component methods.

A component controller is defined with the asynchronous module definition (AMD) syntax. In the `sap.ui.define` statement; the required dependencies can be declared which can be used in the controller.

To create an SAPUI5 component, you extend either the `Component` or `UIComponent` base class and pass the name of the module (namespace + `.Component`).

```
sap.ui.define(['jquery.sap.global', 'sap/ui/core/UIComponent'],
    function(jQuery, UIComponent) {
    "use strict";
    var Component = UIComponent.extend("samples.components.sample.Component", {
        metadata : {
            manifest : "json"
        }
    });
    return Component;
});
```

The metadata of the component controller should be used to declare the runtime metadata only (which are the properties, aggregations, associations and events).

We recommend to define the component metadata externally in the descriptor (`manifest.json`), because the descriptor for components is mandatory for modern components and allows performance optimizations.

Related Information

Using and Nesting Components [page 726]

Component Metadata

The component class provides specific metadata for components by extending the `ManagedObject` class. The `UIComponent` class provides additional metadata for the configuration of user interfaces or the navigation between views.

> **i** Note
>
> With the introduction of the descriptor for applications, components, and libraries, we recommend to migrate the component metadata to the descriptor. The descriptor is inspired by W3C's Web Application Manifest and provides comprehensive information for applications, components and libraries. For more information, see Descriptor for Applications, Components, and Libraries [page 734]. The metadata property `manifest` must be set to `json` to indicate that the `manifest.json` file should be loaded and used:
>
> ```
> sap.ui.core.Component.extend("some.sample.Component", {
>     "metadata": {
>         "manifest": "json"
>     }
> });
> ```
>
> You can also define the descriptor inline by just providing an object. However, we do **not** recommend this because this would prevent that the descriptor can be analyzed by tools.

The metadata defined in `Component.js` is common for faceless components and UI components. The following parameters are available:

- `manifest`: Specifies if your component uses the descriptor
- `abstract`: Specifies if your component class is an abstract class that serves as a base for other components
- `version`: Version of your component; this parameter belongs to the design time metadata and is currently not used; it may be used in the future in the design time repository
- `properties`, `aggregations`, `associations`, and `events`: Define these for your component in the same way as for a control. For more information, see Defining the Control Metadata [page 2188].
- `library`: Specifies the library to which your component belongs to

The following properties are deprecated and no longer needed if you use the descriptor:

- `includes`: Array of strings containing the paths to CSS and JavaScript resources for your component; will be added to the header of the HTML page and loaded by the browser. The resources will be resolved relative to the location of `Component.js`.

- `dependencies`: Used to specify all external dependencies, such as libraries or components. Like the includes for resources that are added to the application's HTML, the dependencies are loaded by SAPUI5 core before the component is initialized. Everything that is referenced here can be used in your component code right from the start. Specify here external dependences such as libraries or components, that will be loaded by SAPUI5 core in the initialization phase of your Component and can be used after it.
  - `libs`: Path to the libraries that should be loaded by SAPUI5 core to be used in your component
  - `components`: Full path to the components that should be loaded by SAPUI5 core to be used in your component
  - `ui5version`: Minimum version of SAPUI5 that the component requires; it helps to be ensure that the features of SAPUI5 runtime used in this component are available. As SAPUI5 currently does not enforce the use of the correct version, it is only used for information purposes.
- `config`: Static configuration; specify the name-value pairs that you need in the component
- `extensions`: Extensions for components and views, see Extending Apps [page 2143]
  - `sap.ui.viewExtensions`: Used for providing custom view content in a specified extension point in the standard application
  - `sap.ui.viewModifications`: Used for overriding control properties in the standard application
  - `sap.ui.viewReplacements`: Used for replacing a standard view with a custom view
  - `sap.ui.controllerExtensions`: Used for extending a controller in a delivered standard application with a custom controller
  - `sap.ui.controllerReplacements`: Used for replacing a controller in a delivered standard application with a custom controller

Example for metadata in `Component.js`:

```
sap.ui.core.Component.extend("some.sample.Component", {
    "metadata": {
        "manifest": "json", // Specifies that your Component class uses the
descriptor via the manifest.json file
        "abstract": true, // Specifies if your Component class is an abstract
one that serves as a base for your other components
        "library": "sap.ui.core", // Specifies the library the component belongs
to
        "version": "1.0", // Version of your Component
        "properties": { // Defined for components in the same way as for a
control or view
            "config": "any"
        }
    }
});
```

In addition to the common metadata for components, the `UIComponent` class provides the following metadata for UI compnents:

- `publicMethods`: Definition of public methods for your component
- `aggregations`: Defines aggregations for your component

The following properties are deprecated and no longer needed if you use the descriptor:

- `rootView`: Can be the view name as string or the view configuration object
- `routing`: Provides the default values for all views
  - `config`: Default values for routing that are applied, if no setting is specified by a route
    - `viewType`: View type of the view that is created, for example XML, JS or HTML
    - `viewPath`: Prefix that is preceding the view

- `targetParent`: ID of the view in which the `targetControl` is searched
- `targetControl`: ID of the control that contains the views
- `targetAggregation`: Name of the aggregation of the `targetControl` that contains views
- `clearTarget`: Boolean; if set to `true`, the aggregation should be cleared before adding the View to it

- `routes`: Contains the configuration objects
  - `name`: Mandatory parameter used for listening or navigating to the route
  - `pattern`: String that is matched against the hash. The {} means this segment of the URL is passed to a handler with the value it contains
  - `view`: Name of the view that is created

Example for UI component metadata:

```
sap.ui.core.UIComponent.extend("some.sample.UIComponent", {
    "metadata": {
        "publicMethods": [ "render" ],
        "aggregations": {
            "rootControl": {
                "type": "sap.ui.core.Control", multiple: false, visibility:
"hidden"
            }
        }
    }
}),
```

Properties Section in Component Metadata

You can add a properties section to the metadata for all properties that can adopt different values during runtime. The getters and setters for these properties are generated automatically, but you can overwrite them if you require additional functionality. The following example contains two properties at the end of the metadata section.

```
sap.ui.core.UIComponent.extend("samples.components.shell.Component", {
    "metadata": {
       "abstract": true,
       "version": "1.0",
[… omitting some lines to make the example shorter]
        "properties": {
          "appTitle": {
               "name":"appTitle",
                "type":"string",
                "defaultValue":"Default Value that will be replaced with
something meaningful through the setter for this property"
            },
            "someOtherProp": {
               "name":"myProperty",
                "type":"string",
                "defaultValue":"Some text"
            }
        }
    }
});
```

The getters and setters for these properties are generated automatically and can be overwritten if additional functionality is required.

Methods Controlling the Initial Instantiation

SAPUI5 provides two methods for the initial instantiation of the component.

You can use the following methods:

- `init`
  Overwrite this method for example to connect the model between the control and the component. This method is **not** called by the application directly, but called automatically when you create the instance of the component. The routing instance needs to be initialized here, see Initializing and Accessing a Routing Instance [page 1081].
- `createContent`
  By default, the UI component creates the `sap.ui5/rootView` declared in the manifest as the root control, see Descriptor Dependencies to Libraries and Components [page 778].
  Alternatively, you can overwrite this method and programmatically create the root control:

```
sap.ui.define(["sap/ui/core/UIComponent", "sap/m/Label"],
function(UIComponent, Label) {
    return UIComponent.extend("my.app.Component", {
        metadata: {
            manifest: "json"
        },
        createContent: function () {
            return new Label({ text: "Hello!" });
        }
    });
});
```

> **i Note**
>
> The configuration properties for a component, that is, the settings given in the constructor or the `sap.ui.core.Component.create` or `sap.ui.component` call, are not available in the `Init` and `createContent` methods. Use `componentData` instead. For more information, see `sap.ui.core.Component.create`.

You can also overwrite the getters and setters for component properties in the `Component.js` file.

Using and Nesting Components

You can use a `ComponentContainer` to wrap a `UIComponent` and reuse it anywhere within the SAPUI5 control tree. With the `ComponentContainer` you can nest components inside other components.

Component Containers

To render UI components, you must wrap them in a `sap/ui/core/ComponentContainer`. You **cannot** use the `placeAt` method to place UI components directly in a page. A `ComponentContainer` carries specific settings and also contains the lifecycle methods of a regular control, such as the `onBeforeRendering` and

`onAfterRendering` methods. The lifecycle methods of the `ComponentContainer` are forwarded to the corresponding methods of the nested component.

The `ComponentContainer` separates the application and the nested component. The control tree and data binding of the inner component are decoupled from the outer component.

If you want to share data with the inner component, you can use the `propagateModel` property on the `ComponentContainer` to forward models and binding contexts to the inner component.

You load and create a `UIComponent` in one of the following ways:

- Load the component asynchronously in "manifest first" mode by specifying the component name:

```
    // "ComponentContainer" required from module "sap/ui/core/
ComponentContainer"
    var oContainer = new sap.ui.core.ComponentContainer({
        name: "samples.components.sample",
        manifest: true,
        async: true
    });
    oContainer.placeAt("target");
```

- Load the component asynchronously before creating the container:

```
    // "Component" required from module "sap/ui/core/Component"
    // "ComponentContainer" required from module "sap/ui/core/
ComponentContainer"
    Component.load({
        name: "samples.components.sample",
    }).then(function(oComponent) {
        var oContainer = new ComponentContainer({
            component: oComponent
        });
        oContainer.placeAt("target");
    });
```

- Load the component asynchronously with "manifest first" mode by specifying the URL of the descriptor (`manifest.json`):

```
    // "Component" required from module "sap/ui/core/Component"
    // "ComponentContainer" required from module "sap/ui/core/
ComponentContainer"
    Component.load({
        manifest: "samples/components/sample/manifest.json",
    }).then(function(oComponent) {
        var oContainer = new ComponentContainer({
            component: oComponent
        });
        oContainer.placeAt("target");
    });
```

> **i Note**
>
> You can use the `lifecycle` property to determine whether the container or your application code will take care of destroying the component.
>
> See `ComponentContainer` for a detailed explanation of the lifecycle property and its possible values.

Using a Component Container to Load Components from a Different Location

You may want to load components from a location that is different from the location where the SAPUI5 libraries are located or a location that is not registered as a resource root in the SAPUI5 bootstrap.

You can do so by defining the URL of the additional components as a setting for the component factory or the component container.

- Loading the component asynchronously before creating the container:

```
    // "Component" required from module "sap/ui/core/Component"
    // "ComponentLifecycle" required from module "sap/ui/core/
ComponentLifecycle"
    Component.load({
        name: "samples.components.sample",
        url: "./myComponents"
    }).then(function(oComponent) {
        var oContainer = new ComponentContainer({
            component: oComponent
        });
        oContainer.placeAt("target");
    });
```

- Loading the component asynchronously when creating the container:

```
    // "ComponentContainer" required from module "sap/ui/core/
ComponentContainer"
    // "coreLibrary" required from module "sap/ui/core/library"
    var oContainer = new ComponentContainer({
        name: "samples.components.sample",
        lifecycle: coreLibrary.ComponentLifecycle.Container,
        async: true,
        url: "./myComponents"
    });
    oContainer.placeAt("target");
```

  Here you use the `lifecycle` property to make sure that the component is destroyed when the container is destroyed.

Reuse Components

To be able to reuse a component, the component has to be declared in the `componentUsages` section of the `manifest.json` descriptor file as follows:

```
"sap.ui5": {
  "componentUsages": {
    "myreuse": {
      "name": "sap.reuse.component",
      "settings": {},
      "componentData": {},
      "lazy": false
    }
  }
}
```

The reuse component is declared via its `componentUsage` ID as the key and the supported values are `name` (name of the component), `settings`, `componentData` and `lazy`. The values defined in the `manifest.json` file will be merged with the values specified in the instance-specific component factory function An exception

to this is the lazy flag which is an indicator for the Component factory function how to handle the dependency. Allowed values in the instance-specific factory function are `settings`, `componentData`, `async`, and `id`.

The `lazy` flag is used to indicate whether the Component should be already preloaded or not. By default, the Components defined in the usage are lazy. A Component preloaded with the flag `lazy: false` has to be explicitly maintained in the `manifest.json`.

For more information, see Descriptor for Applications, Components, and Libraries [page 734].

If you want to exchange the reuse component, for example, to extend an app, you simple exchange the reuse component in the `manifest.json` descriptor file.

The application index can also access the information in the `manifest.json` file and optimize the determination of dependencies when loading components.

Reuse components that are embedded by a library must have an explicit entry in the `manifest.json` in the `sap.app/embeddedBy` section:

```
"sap.app": {
  "embeddedBy": "../"
}
```

Under `embeddedBy`, you specify the relative path to the namespace root of the library. This ensures that tools like the application index can discover embedded libraries and won't include them in the transitive scope (otherwise you would get unwanted 404 requests). Additionally tools should declare a library dependency to the embedding library. This will ensure that the library containing the component preload will be loaded automatically instead of the trying to load the component preload by itself.

Instantiation

To instantiate the reuse component in the current component, you use an instance-specific factory function. The factory function requires at least the `componentUsage ID` as a parameter (simplified usage) or a configuration object that contains the `usage` and optionally `settings` and `componentData` (extended usage).

- Example for simplified usage (Async):

  ```
  this.createComponent("myreuse").then(function(oComponent) {
    // ...
  });
  ```

- Example for extended usage (Async):

  ```
  var oComponentPromise = this.createComponent({
    usage: "myreuse"
    settings: {},
    componentData: {},
    async: true
  });
  ```

Declarative Usage

You can also declare a reuse component directly, for example, in your JavaScript or XML code. In an XML view, the local service factory can only be used via the `ComponentContainer` that has a superordinate component.

```
<View ...>
  <ComponentContainer usage="myreuse" async="true"></ComponentContainer>
</View>
```

Migration

If you have been reusing components before we introduced the reuse feature described above, we recommend that you refactor your code and implement the new logic.

If you use a component that is embedded in a library, and the application declares a dependency to that library, remove the dependency to the library from the embedding application. Make sure that the application code does not contain any direct references to the component or the embedding application.

Old Code

`manifest.json` with dependency declaration only:

```
{
  "sap.ui5": {
    "dependencies": {
      "components": {
        "sap.reuse.component": {}
      }
    }
  }
}
```

Recommended Code

`manifest.json` with declaration of reuse components:

```
{
  "sap.ui5": {
    "dependencies": {
      "components": {
        "sap.reuse.component": {}
      }
    },
    "componentUsages": {
      "reuse": {
        "name": "sap.reuse.component",
        "lazy": false
      }
    }
  }
}
```

> **i Note**
>
> As of version 1.56 it is sufficient to declare the component usage and to indicate whether the component should be lazy loaded or not. The declaration of the component dependencies can and should be avoided in this case.

`Component.js` with nested reuse component:

```
createContent: function() {

  var oReuseComponent =
sap.ui.component({
    "name": "sap.reuse.component"
  });

}
```

`Component.js` that loads the reuse component

```
createContent: function() {

  var oReuseComponentPromise =
this.createComponent({ /* this =
Component instance */
    "usage": "reuse"
  });

}
```

Enabling Routing in Nested Components [page 1086]

API Reference: `sap.ui.core.ComponentContainer`

API Reference: `sap.ui.core.ComponentContainer.setLifecycle`

Descriptor for Applications, Components, and Libraries [page 734]

Declarative API for Initial Components

The declarative API enables you to define the initially started component directly in the HTML markup.

Using the `ComponentSupport` Module

With the declarative `sap/ui/core/ComponentSupport` API it is possible to define the initially started component directly in the HTML markup instead of the imperative way using JavaScript. The declarative `ComponentSupport` is not activated by default, but must be enabled via the bootstrap:

```
<!-- index.html -->
<script id="sap-ui-bootstrap"
    src="/resources/sap-ui-core.js"
    ...
    data-sap-ui-oninit="module:sap/ui/core/ComponentSupport"
    ...>
</script>
```

This module scans the DOM for HTML elements containing a special data attribute named `data-sap-ui-component`. All DOM elements marked with this data attribute will be regarded as container elements into which a `sap/ui/core/ComponentContainer` is inserted. Additional data attributes are then used to define the constructor arguments of the created `ComponentContainer` instance, e.g. `data-name` for the name of the component which should be instantiated:

```
<!-- index.html -->
<body id="content" class="sapUiBody sapUiSizeCompact" role="application">
    ...
    <div data-sap-ui-component
        data-id="container"
        data-name="sap.ui.core.samples.formatting"
        ...
        data-handle-validation="true"
        ...>
    </div>
    ...
</body>
```

Declarative Configuration of `ComponentContainer`

As HTML is case-insensitive, in order to define a property with upper-case characters, you have to "escape" them with the hyphen character. This is similar to CSS attributes. In the following sample the `handleValidation` argument of the `ComponentContainer` constructor is used:

```
<div data-sap-ui-component ... data-handle-validation="true" ...></div>
```

Asynchronouos loading with `ComponentSupport`

The `ComponentSupport` module enforces asynchronous module loading of the component with "manifest first". This means, that the `manifest.json` file is loaded before evaluating the component to optimize loading behavior. In this way libraries and other dependencies can be loaded asynchronously and in parallel. To achieve this, the following settings for the ComponentContainer are applied by default:

- `async` {*boolean*} (forced to `true`)
- `manifest` {*boolean|string*} (forced to `true` if no string is provided to ensure manifest first)
- `lifecycle` {*sap.ui.core.ComponentLifecycle*} (defaults to `Container`)
- `autoPrefixId` {*boolean*} (defaults to `true`)

For details on the manifest, see Descriptor for Applications, Components, and Libraries [page 734].

See also `ComponentSupport` and `ComponentContainer` for more information.

Delay the Initial Component Instantiation

In some cases, the component initialisation must wait until all pre-required modules have been loaded. If this is the case, the `ComponentSupport` module needs to be executed later, and you have to replace the `onInit` module execution in the bootstrap with a custom module:

```
<!-- index.html -->
<script id="sap-ui-bootstrap"
    src="resources/sap-ui-core.js"
    data-sap-ui-onInit="module:sap/ui/demo/myBootstrap"> <!-- Execute custom
module on init -->
</script>
```

The custom module can load dependencies and execute code before activating the `ComponentSupport` module:

```
// sap/ui/demo/myBootstrap.js
sap.ui.define(["sap/ui/demo/MyModule"], function(MyModule) {
    // Execute code which needs to be executed before component initialization
    MyModule.init().then(function() {
        // Requiring the ComponentSupport module automatically executes the
component initialisation for all declaratively defined components
        sap.ui.require(["sap/ui/core/ComponentSupport"]);
    });
});
```

Handling IDs in UI Components

Components are usually used with a root view and in this case, the component handles the prefixing of IDs of views, elements, or controls, with the component ID.

This works similar to the prefixing of control IDs in XML views, see Support for Unique IDs [page 814]. However, if you implement your own `createContent` function, you need to handle this yourself. The following two options exist:

- Set the `sap.ui5/autoPrefixId` attribute in the `manifest.json` file to `true`. This is the easiest option.
- Use the `createId` function of the UI component to prefix the respective ID of a view, element, or control yourself.

Use the `byId` function of the UI component to retrieve the views, controls, and elements that have been created in a UI component.

Advanced Concepts for SAPUI5 Components

Advanced concepts for components include routing and navigation and component data as well as the event bus.

The following advanced concepts for components exist.

- Routing and navigation
  UI components support the routing and navigation concept, see Initializing and Accessing a Routing Instance [page 1081].
- Extensibility and customizing
  The extensibility and customizing concept allows you to extend and modify components in order to replace and extend the views and controllers as well as to modify the views. A customization can be performed, for example, on a custom application that extends a delivered standard application.
  For more information, see Extending Apps [page 2143]
- Component data
  The JSON object `ComponentData` contains any initial values of parameters that can be used in the `createComponent()` method. Component data are already available for use in the `createComponent()` method, but not the parameters. The parameters are available in the `onBefore`, the `onAfterRendering` and the setter methods of the parameters.
  Component data is provided from outside and can be configured as desired. Configuration data is static and defined in the component. To change or extend the configuration, the component needs to be extended and a new configuration has to be created and merged with the configuration in the parent component.
- Event bus of the component
  The local event bus belongs to the component and can be used by all children of this component. Once a component instance is destroyed, the listeners registered in the event bus are destroyed automatically. For more information, see API Reference for the `getEventBus` method of `sap.ui.core.Component`.

Descriptor for Applications, Components, and Libraries

The descriptor for applications, components, and libraries is inspired by the Web Application Manifest concept introduced by the W3C. The descriptor provides a central, machine-readable and easy-to-access location for storing metadata associated with an application, an application component, or a library.

The data is stored in json format in the `manifest.json` file. The developer creates the file with attributes in different namespaces. It contains, for example, the app ID, the version, the data sources used, along with the required components and libraries. The existence of the `manifest.json` file must be declared in the component metadata, which is then delivered as part of the application archive. After delivery, the file is read-only.

General Information

Every new version of SAPUI5 implies a new version of the app descriptor. In the following table you can see how the SAPUI5 version is related to the descriptor version and the value of `_version`.

Table 11: AppDescriptor Release and SAPUI5 Version

AppDescriptor Release	SAPUI5 Version	_version
Version 2	>=1.30	1.1.0
Version 3	>=1.32	1.2.0
Version 4	>=1.34	1.3.0
Version 5	>=1.38	1.4.0
Version 6	>=1.42	1.5.0
Version 7	>=1.46	1.6.0
Version 8	>=1.48	1.7.0
Version 9	>=1.50	1.8.0
Version 10	>=1.52	1.9.0
Version 11	>=1.54	1.10.0
Version 12	>=1.56	1.11.0
Version 13	>=1.58	1.12.0
Version 14	>=1.61	1.13.0
Version 15	>=1.62	1.14.0
Version 16	>=1.66	1.15.0

AppDescriptor Release	SAPUI5 Version	_version
Version 17	>=1.70	1.16.0
Version 18	>=1.71	1.17.0

For more information on the new fields introduced in each version, check out Migration Information for Upgrading the Descriptor File [page 775]

Manifest First Function

The component factory function `Component.create`, as introduced with 1.58, loads the `manifest.json` by default before the component instance is created. With this, you can preload the dependencies (libraries and components) and, thus, improve the performance for loading the component. The preload is also available for models, which can be flagged for preload during component loading.

The `manifest` option allows to configure when and from where the descriptor is loaded:

- Default, equivalent to setting `manifest` to `true`.

```
// "Component" required from module "sap/ui/core/Component"
// load manifest.json from default location and evaluate it before creating
an instance of the component
Component.create({
  name: "sap.my.component",
});
```

- Specify an alternative URL as parameter for `manifest` for the component factory function:

```
// "Component" required from module "sap/ui/core/Component"
// load via manifest URL
Component.create({
  name: "sap.my.component",
  manifest: "any/location/sap/my/component/manifest.json"
});
```

- Suppress loading the manifest by setting the `manifest` flag to `false`, for example, when a legacy component does not have one:

```
// "Component" required from module "sap/ui/core/Component"
// load component without loading a manifest first
Component.create({
  name: "sap.my.component",
  manifest: false
});
```

> **i Note**
>
> When you enable `manifest`, all legacy component metadata needs to be migrated into the descriptor for applications/components. Only those entries in the descriptor for components will be respected by the component and all other entries will be ignored.

Descriptor Content

> **i Note**
>
> You can find an example `manifest.json` file with sample code for the descriptor content here [page 749].

The content for the descriptor is contained in the following namespaces: `without`, `sap.app`, `sap.ui`, `sap.ui5`, `sap.platform.abap`, `sap.platform.hcp` and `sap.fiori`. The following tables show the application-specific attributes provided by the respective namespaces:

No Namespace

Table 12: Attributes in the `without` namespace

Attribute	Description
`start_url`	Start page of your app, if available

`sap.app`

Table 13: Attributes in the mandatory `sap.app` namespace

Attribute	Description
`id`	Mandatory attribute: Unique identifier of the app, which must correspond to the component name **i Note** The ID must not exceed 70 characters. It must be unique and must correspond to the component name. This is checked in consistency check reports, for example, for the SAPUI5 application index which returns an error in case of duplicate IDs, see SAPUI5 Application Index [page 1525].
`type`	Possible values: • `application` • `component` • `library` • `card`

Attribute	Description
`i18n`	Relative URL to the properties file that contains the text symbols for the descriptor; default: `"i18n/i18n.properties"` **i Note** The path to the i18n file must not exceed 100 characters.
`applicationVersion`	Mandatory version of the app (semantic version with the following format `major.minor.patch`)
`embeds`	Array of relative paths to the nested `manifest.json` files; attribute is mandatory if a nested `manifest.json` exists
`embeddedBy`	Relative path back to the `manifest.json` file of an embedding component or library; attribute is mandatory for a nested `manifest.json`
`title`	Mandatory attribute: The entry is language-dependent and specified via `{{...}}` syntax
`subTitle`	Language-dependent entry for a subtitle; specified via `{{...}}` syntax
`shortTitle`	Short version of the title. Language-dependent entry has to be specified via `{{...}}` syntax
`info`	Needed for CDM (Common Data Model) conversion of tiles. Language-dependent entry has to be specified via `{{...}}` syntax
`description`	Description; language-dependent entry that is specified via `{{...}}` syntax
`tags`	Contains the following: • An array of language-dependent `keywords` that are specified via `{{...}}` syntax, for example `"keywords": ["{{keyWord1}}","{{keyWord2}}"]`. • An array of `technicalAttributes` (general technical attributes, for example, technical catalog, upper case and language-independent attributes).

Attribute	Description
`ach`	Application component hierarchy (SAP's component names for bug reports); attribute is mandatory for SAP apps, but is not used so far for apps developed outside SAP

`dataSources`	Unique key/alias for specifying the used data sources; contains the following information:
	• `uri`: Mandatory relative URL in the component; takes `embeddedBy` into account, if filled, or the server absolute of the data source, for example `"/sap/opu/odata/snce/PO_S_SRV;v=2/"`
	• `type`: OData `(default)or ODataAnnotation or INA or XML or JSON`
	• `settings`: Data source type-specific attributes (key, value pairs), which are:
	  ○ `odataVersion`: 2.0 (default), 4.0
	  ○ `localUri`: Relative URL to local metadata document or annotation uri
	  ○ `annotations`: Array of annotations which references an existing data source of type "ODataAnnotation" under **sap.app/dataSources**
	  ○ `maxAge`: Indicates the number of seconds the client is willing to accept with regard to the age of the data that is requested

`cdsViews`	Array of directly used CDS views This attribute is optional and only added if used via INA protocol directly, not if used via OData service.
`offline`	Indicates whether the app is running offline; default is `false` (online)
`sourceTemplate`	If an app has been generated from a template, this attribute is filled automatically by the generation tool (SAP Web IDE): • `id`: Mandatory ID of the template from which the app was generated • `version`: Mandatory version of the template from which the app was generated

Attribute	Description
`openSourceComponents`	Array of directly used open source libraries for documentation purposes; not used when open source libraries are used via SAPUI5 capsulation • `name`: Mandatory name of the open source component • `version`: Required if the open source component is part of the app; not required if the open source component is part of the SAPUI5 dist layer • `packagedWithMySelf`: Indicates if the open source component is part of the app (`true`) or not (`false`)
`provider`	Name of the provider that owns the application. Current supported enum value is `sfsf`.

Attribute	Description
`crossNavigation`	Cross-navigation for specifying inbounds and outbounds • `scopes`: Scope of a site `sapSite` • `inbounds`: Unique key or alias to specify inbounds (mandatory); contains: ○ `semanticObject` (mandatory) ○ `action` (mandatory) ○ `icon`: Used to overwrite `sap.ui/icons/icon` ○ `title`: Used to overwrite `sap.app/title` (language-dependent entry to be specified via {{...}} syntax) ○ `subTitle`: Used to overwrite `sap.app/subTitle` (language-dependent entry to be specified via {{...}} syntax) ○ `shortTitle`: Used to overwrite `sap.app/shortTitle` (language-dependent entry to be specified via {{...}} syntax) ○ `info`: Language-dependent entry to be specified via {{...}} syntax ○ `displayMode`: <`ContentMode` or `HeaderMode`> Display mode for an inbound which specifies what kind of tile is displayed. A static tile can be displayed in content mode or header mode. The tile in header mode is a text only tile without an icon which allows longer title and subtitle. ○ `hideLauncher` (`true/false`): Indicates that an inbound must not be represented as a tile/link ○ `indicatorDataSource`; specifies the data source; contains: ○ `dataSource`: reference to `sap.app/dataSources` (mandatory) ○ `path`: Relative path to `sap.app/dataSources uri` (mandatory) ○ `refresh`: Defines the refresh interval ○ `deviceTypes`: Contains objects with device types on which the app is running; if empty, use the default from `sap.ui/deviceTypes`; the following device types can be defined (`true/false`): ○ `desktop` ○ `tablet`

Attribute	Description
	○ `phone` ○ `signature`: Specifies the signature; contains: ○ `parameters` (mandatory): Contains parameter names with the following information: ○ `required` (`true/false`) ○ `filter`: Represents the filter only if the input parameter matches the filter; with a mandatory `value` and `format` attribute ("plain", "regexp", "reference") ○ `defaultValue`: Specifies the default value; has mandatory attributes `value` (depending on the format this is a verbatim default value) and `format` ("plain", "reference"). If the `format` is "reference", the syntax for the `value` is as follows: `"UserDefault.<parameterName>"` for single-value parameters, `"UserDefault.extended.<parameterName>"` for sets of values and value ranges, or `"User.env.<parameterName>"` for supported user-specific settings. ○ `renameTo`: Used for parameter mapping to specify the parameter name in legacy ABAP applications, for example, `RF05L_BUKRS` for the `CompanyCode` parameter ○ `launcherValue`: Represents a value to be used when creating an tile intent for this inbound with value and format ("plain", "array") ○ `additionalParameters` (mandatory): Indicates how additional parameters to the declared signature are handled; values can be, for example, "ignored", "notallowed", "allowed" • `outbounds`: Specifies outbounds with a unique key or alias containing: ○ `semanticObject` (mandatory) ○ `action` (mandatory) ○ `parameters`: Specifies the parameter name

Attribute	Description
	○ `value`: Represents a value to be used in the outbound; with `value` (verbatim value for format "plain", or not supplied, or a binding reference for format "binding") and `format` (indicates how value is to be interpreted, "plain", "binding") ○ `required`: Indicator whether paramter is required (`true`, `false`) ○ `additionalParameters`: Indicates whether additional context parameters are to be used: ○ `ignored`: Parameters are not used ○ `allowed`: Parameters are passed on to application

`sap.ui`

Table 14: Attributes in the mandatory `sap.ui` namespace

Attribute	Description
`technology`	Specifies the UI technology; value is `UI5`
`icons`	Contains object with app-specific icons, which are: • `icon`: Icon of the app, can be chosen from Icon Explorer . • `favIcon`: ICO file to be used inside the browser and for desktop shortcuts **i Note** `favIcon` is not set automatically by the framework. The icons can be set manually using the `sap/ui/util/Mobile` module and the `setIcons` function. • `phone`: 57x57 pixel version for non-retina iPhones • `phone@2`: 114x114 pixel version for retina iPhones • `tablet`: 72x72 pixel version for non-retina iPads • `tablet@2`: 144x144 pixel version for retina iPads

Attribute	Description
`deviceTypes`	Mandatory; contains objects with device types on which the app is running, such as: • `desktop`: Indicator for whether desktop devices are supported, `true` (default), `false` • `tablet`: Indicator for whether tablet devices are supported, `true` (default),`false` • `phone`: Indicator for whether phone devices are supported, `true` (default),`false`
`supportedThemes`	Optional; array of supported SAP themes, such as `sap_hcb`, `sap_belize`
`fullWidth`	Indicates whether an app shall run in full screen mode (`true`), or not (`false`)

`sap.ui5`

The `sap.ui5` namespace is aligned with the previous component metadata and contributes the following SAPUI5-specific attributes for the application descriptor, see Migrating from Component Metadata to Descriptor [page 756] for more details.

Table 15: Attributes in the `sap.ui5` namespace

Attribute	Description
`resources`	Relative URLs in the component, taking `embeddedBy` into account if filled, pointing to `js` (JavaScript) and `css` resources that are needed by the app for specifying the mandatory `uri` and an `id` (optional) for CSS. The JavaScript files are loaded by the `require` mechanism. The CSS files are added to the head of the HTML page as a link tag. The resources are resolved relative to the location of the `manifest.json` file.

Attribute	Description
`dependencies`	Mandatory; specifies the external dependencies that are loaded by the SAPUI5 core during the initialization phase of the component and used afterwards. These are the following libraries or components: • `minUI5Version`: Mandatory; Minimum version of SAPUI5 that your component requires; this information ensures that the features of the SAPUI5 runtime version of the component are available. As SAPUI5 does not currently enforce use of the correct version, the `minUI5Version` is used for information purposes only. If the minimum SAPUI5 version criteria is not fulfilled, a warning is issued in the console log. • `libs`: ID (namespace) of the libraries that the SAPUI5 core should load for use in the component. If your app requires a minimum version of the lib, specify the `minVersion` for information purposes. Specify `lazy` to indicate that the lib shall be lazy loaded. • `components`: ID (namespace) of the components that the SAPUI5 core should load for use in your component. If your app requires a minimum version of the component, specify the `minVersion` for information purposes. Specify `lazy` to indicate that the component shall be lazy loaded. For more information, see Descriptor Dependencies to Libraries and Components [page 778].
`componentUsages`	Specifies the used components with the a unique key/alias. Contains the following: • `name`: Mandatory name of the reuse component • `settings`: Settings of the component • `componentData`: Component data of the component • `lazy`: Indicates whether the component usage should be lazily loaded. Default value: `true` For more information see:Using and Nesting Components [page 726]

Attribute	Description
`models`	Defines models that should be created or destroyed along the component's lifecycle. The key represents the model name. Use an empty string ("") for the default model. • `type`: Model class name • `uri`: Relative URL in the component, taking `embeddedBy` into account if filled, or server for absolute model • `settings`: Object that is passed to the model constructor. **Example** You can overwrite the default binding mode with the `defaultBindingMode` attribute (enumeration of type `sap.ui.model.BindingMode`, with values. `Default`, `OneTime`, `OneWay`, `TwoWay`). For OData models constructor see the following: ○ sap.ui.model.odata.ODataModel ○ sap.ui.model.odata.v2.ODataModel ○ sap.ui.model.odata.v4.ODataModel For ResourceModel constructor see: ○ sap.ui.model.resource.ResourceModel The attribute `enhanceWith` can be specified with `bundleUrl`, `bundleUrlRelativeTo` (default: `component` or `manifest`) or `bundleName` to provide a list of additional resource bundle configurations to enhance the `ResourceModel` with. • `dataSource`: String of key or alias from `sap.app dataSources` to reference an existing data source; the `type`, `uri` and `settings` properties are set according to the data source's `type`, `uri` and `settings` (if not already defined). If the type under `sap.app dataSources` is `OData`, an OData Model V2 is created automatically. If you need an OData Model V1, specify the `type` as well. • `preload`: Optional; Boolean with `true`, `false` (default) Defines whether or not the model is initialized (preloaded) before the component instance is created and while loading the component preload and its dependencies. For more information, see Manifest Model Preload [page 781].

Attribute	Description
`rootView`	Specifies the root view that shall be opened; can be the view name as a string for XML views, or the view configuration object with `viewName` for the view name as a string and `type` for the type (enumeration of sap.ui.core.mvc.ViewType), **id**, **async** and other properties of `sap.ui.core.mvc.view`.
`autoPrefixId`	true, false (default), Enables the auto prefixing for the UIComponent for IDs of ManagedObjects (controls or elements) which are created in the context of the `createContent` function, or any other invocation of the `Component.prototype.runAsOwner()` function (for example a component's router uses this method when creating new views). In former SAPUI5 releases this prefixing of the ID needed to be done with `oComponent.createId` by overwriting the method `getAutoPrefixId`. The same can now be achieved declaratively by setting `autoPrefixId` to true.
`handleValidation`	Possible values: `true` or `false` (default); used to enable or disable validation handling by the message manager for this component, see Error, Warning, and Info Messages [page 1063]
`config`	Static configuration; specify the name-value pairs that you need in your component.
`routing`	Provides configuration parameters for route and router, see Routing and Navigation [page 1072]
`extends`	Used to extend another component. • `component`: ID (namespace) of the component being extended • `minVersion`: Specifies the minimum version of the component being extended, for information purposes if your app requires a minimum version of the component • `extensions`: Component or view extensions, which enable you to replace and extend views and controllers and also to modify the views, see Extending Apps [page 2143]

Attribute	Description
`contentDensities`	Mandatory; contains an object with the content density modes that the app supports, see Content Densities [page 1142] • `compact`: Mandatory; indicates whether compact mode is supported (`true`, `false`) • `cozy`: Mandatory; indicates whether cozy mode is supported (`true`, `false`)
`resourceRoots`	Map of URL locations keyed by a resource name prefix; only relative paths inside the component are allowed and no ".." characters This attribute is intended for actual sub-packages of the component only, meaning that it must not be used for the component namespace itself. **i Note** When loading with *manifest first* (by using the property `manifest`), the `resourceRoots` are evaluated before the component controller is loaded. Otherwise, the defined resource roots will be registered after the component controller is loaded and do not affect the modules being declared as dependencies in the component controller.
`componentName`	Name of the SAPUI5 component
`appVariantIdHierarchy`	Needed for an app variant scenario to reference UI flex changes from layers below. An array of `appVariantId` hierarchy with origin layer and version, calculated attribute and filled automatically during variant merge.
`i18n`	Determines if the library contains a i18n resource or not. If using a string instead of a boolean value, an alternative name for the i18n resource could be defined. **i Note** If your SAP Fiori library benefits from the new attribute `sap.ui5/library/i18n`, adoption is recommended. This is only the case if the main resource bundle (properties file) used by the SAP Fiori Library is different than the default name `messagebundle.properties`

Attribute	Description
`flexEnabled`	Determines whether the app is enabled for adaptation flex enabled (for example, using stable IDs); possible values are `true`, `false` or `undefined` (default) For more information, see SAPUI5 Flexibility: Enable Your App for UI Adaptation [page 1450].
`commands`	Specifies provided commands with a unique key/alias. Contains: • `shortcut`: String that describes a key combination. When the user presses the key combination, the command is triggered.

`sap.platform.abap`

Table 16: Attributes in the `sap.platform.abap` namespace

Attribute	Description
`uri`	Specifies the app's URI in the ABAP system, for example `/sap/bc/ui5_ui5/sap/appName`; filled during deployment.

`sap.platform.hcp`

Table 17: Attributes in the `sap.platform.hcp` namespace

Attribute	Description
`uri`	Specifies the URI inside the SAP Cloud Platform HTML5 application; filled during deployment, default is ""
`providerAccount`	Specifies the name of the provider account; filled during deployment
`appName`	Specifies the name of the deployed HTML5 application; filled during deployment
`appVersion`	Specifies the version of the deployed HTML5 application; filled during deployment

`sap.fiori`

Table 18: Attributes in the `sap.fiori` namespace

Attribute	Description
`registrationIds`	Array of registration IDs, for example, the Fiori IDs for SAP Fiori apps

Attribute	Description
`archeType`	Mandatory archetype of the app, possible values `transactional`, `analytical`, `factsheet`, `reusecomponent`, `fpmwebdynpro`, `designstudio`

`sap.card`

Table 19: Attributes in the `sap.card` namespace

Attribute	Description
`type`	Describes the card type; possible values are `list` and `analytical`
`header`	Specifies the card's header area
`content`	Specifies the type-dependent card content

`_version`

- On root level (no namespace) Describes the descriptor format version (mandatory). Needs to be updated when migrating to a new descriptor format version, see Migrating from Component Metadata to Descriptor [page 756]
- Inside namespace: Describes the namespace format version (optional from version 1.38 on)

Example

Current version of the `manifest.json`

```

For the following namespaces, the indicated teams are responsible:

- sap.mobile - in Mobile responsibility
- sap.flp - in SAP Fiori Launchpad responsibility
- sap.ui.generic.app - in SAP Fiori Elements responsibility
- sap.ovp - in Overview Page responsibility
- sap.ui.smartbusiness.app - in Smart Business responsibility
- sap.wda - in Web Dypro ABAP responsibility
- sap.gui - in SAP GUI responsibility
- sap.cloud.portal - in SAP Cloud Portal responsibility
- sap.apf - in Analysis Path Framework responsibility
- sap.platform.cf - in Cloud Foundry/XSA responsibility
- sap.map - in SAP Visual Business responsibility
- sap.fe - in SAP Fiori Elements responsibility
- sap.url - in SAP Fiori Launchpad responsibility
- sap.platform.sfsf - for SAP SuccessFactors specific attributes
- sap.wcf - for WCF Application specific attributes
- sap.cloud - for SAP Cloud Platform specific attributes
- sap.card - in SAPUI5 responsibility
- sap.platform.mobilecards - in Mobile Cards responsibility

Declaration in Component Metadata

The component declares the existence of the application descriptor by specifying `manifest: "json"` in the component metadata. Setting this flag makes the component load the `manifest.json` file and read the relevant entries for SAPUI5. This metadata is used to define the dependencies that need to be loaded in order to start the component. The following code snippet shows how to add the manifest link:

```
sap.ui.define(['sap/ui/core/UIComponent'], function(UIComponent) {

    return UIComponent.extend("sap.samples.Component", {
        metadata  : {
            manifest: "json"
        }
    });
});
```

SAPUI5 API

At runtime, the `manifest.json` content can be accessed from the component via the component metadata:

```
// get the component class
sap.ui.require(['sap/samples/Component'], function(SampleComponent) {
    // getting complete manifest from component metadata
```

```
    SampleComponent.getMetadata().getManifest();
    //or getting a namespace
    SampleComponent.getMetadata().getManifestEntry("sap.app");

});
```

sap.ui.core.UIComponent
Component Metadata [page 723]

Migrating from Component Metadata to Descriptor

Overview, how the component metadata are mapped to the descriptor.

For compatibility reasons, the mapping to the `manifest.json` file is done automatically. If a metadata property has been defined, it can also be consumed via the corresponding property of the `manifest.json` file. For a detailed step-by-step guide, see Creating a Descriptor File for Existing Apps [page 764].

> **i Note**
>
> To benefit from the performance improvements that can be achieved by using “manifest first”, we recommend to migrate the component metadata to the descriptor (`manifest.json`). For more information about manifest first, see the *Manifest First Function* section in Descriptor for Applications, Components, and Libraries [page 734].

Table 20: Mapping Table

Metadata	Descriptor	Comment
Component namespace	`sap.app/id`	-
`version`	`sap.app/applicationVersion/version`	-
`config`	`sap.ui5/config`	-
`dependencies`	`sap.ui5/depedencies`	Different format, see *Dependencies* section below
`customizing`	`sap.ui5/extends/extensions`	-
`handleValidation`	`sap.ui5/handleValidation`	-
`includes`	`sap.ui5/resources`	Different format, see *Resources* section below

Metadata	Descriptor	Comment
`rootView`	`sap.ui5/rootView`	-
`routing`	`sap.ui5/routing`	-

Dependencies

Libraries and components are objects and not arrays. For the descriptor part, we use `ui5version` instead of `minUI5Version`.

Metadata

```
"dependencies": {
    "ui5version": "1.30.0",
    "libs": [
        "sap.m",
        "sap.ui.unified"
    ],
    "components": [ "sap.app.otherComponent" ]
}
```

Descriptor

```
"dependencies": {
    "minUI5Version": "1.30.0",
    "libs": {
        "sap.m": {},
        "sap.ui.unified": {}
    },
    "components": {
        "sap.app.otherComponent": {}
    }
}
```

Resources

Includes are renamed to resources and are objects and not an array.

Metadata

```
"includes": ["script.js", "style.css"]
```

Descriptor

```
"resources": {
    "js": [
        {
            "uri": "script.js"
        }
    ],
    "css": [
```

```
        {
            "uri": "style.css"
        }
    ]
}
```

Descriptor for Libraries

The descriptor for libraries contains a subset of the attributes in the descriptor for applications and components.

manifest.json	.library	Available for SAPUI5 dist libraries?	Comment
`sap.app/id`	`name`	x	
`sap.app/type`	-	x	Generated with value `library`
`sap.app/embeds`	-	x	Generated
`sap.app/i18n`	`appData/manifest/i18n`		New in `.library`
`sap.app/applicationVersion/version`	`version`	x	
`sap.app/title`	`title`	x	Text symbol syntax with leading curly brackets (`{{`) and trailing curly brackets (`}}`); new in `.library`
`sap.app/description`	`documentation`	x	Text symbol syntax with leading curly brackets (`{{`) and trailing curly brackets (`}}`)
`sap.app/ach`	`appData/ownership/component`	x	
`sap.app/openSourceComponents`	`appData/manifest/openSourceComponents`		New in `.library`
`sap.app/resources`	-	x	Generated with value `resources.json`

manifest.json	.library	Available for SAPUI5 dist libraries?	Comment
sap.app/offline	appData/manifest/offline	x	New in .library
sap.app/sourceTemplate	appData/manifest/sourceTemplate		New in .library, to be filled by SAP Web IDE only
sap.ui/technology	-	x	Generated with value UI5
sap.ui/deviceTypes	appData/manifest/deviceTypes		New in .library
sap.ui/supportedThemes	-	x	Generated and merged
sap.ui5/dependencies/minUI5Version	-	x	Generated
sap.ui5/dependencies/libs	dependencies	x	
sap.ui5/contentDensities	appData/manifest/contentDensities		New in .library
sap.platform.abap/uri	appData/manifest/sap.platform.abap/uri		New in .library
sap.platform.hcp/uri	appData/manifest/sap.platform.hcp/uri		New in .library
sap.fiori/registrationIds	appData/manifest/sap.fiori/registrationId		New in .library
sap.fiori/archeType	appData/manifest/sap.fiori/archeType		New in .library

Descriptor for Components (Inside Libraries)

The descriptor for components contains a subset of the attributes in the descriptor for applications

Table 21: Attributes in the `sap.app` namespace

Attribute	Comment
`id`	Mandatory
`type`	With value `component`; mandatory
`i18n`	Path relative to component; default is `"i18n/i18n.properties"` Path back to library is also possible, for example via `"../i18n/i18n.properties"`
`embeddedBy`	Mandatory, for example, `"../"`
`title`	Mandatory
`subTitle`	
`description`	
`ach`	
`dataSources`	
`cdsViews`	
`resources`	Mandatory; must have value `resources.json` as file; it is generated by the library build with this name
`offline`	
`sourceTemplate`	

Table 22: Attributes in the `sap.ui` namespace

Attribute	Comment
`technology`	With value `UI5`; mandatory
`deviceTypes`	
`supportedThemes`	

Table 23: Attributes in the `sap.ui5` namespace

Attribute	Comment
`resources`	
`dependencies`	`libs` `components`
`models`	
`rootView`	
`handleValidation`	
`config`	
`routing`	
`extends`	`component` `minVersion`
`contentDensities`	
`componentName`	

Table 24: Attributes in the `sap.mobile` namespace

Attribute	Comment
`definingRequests`	

Library Name Determination

SAPUI5 determines the library name by analyzing the component namespace (package) up to the part where the segment starts with a capitalized letter. If the library name that has been determined, does not fit your component, an additional library attribute needs to be filled in the component metadata in `Component.js` to specify the library your component belongs to.

Example:

```
sap.ui.core.UIComponent.extend("com.sap.fancylibrary.sub.CompLib.Component", {
    metadata : {
        "manifest" : "json",
        "library" : "com.sap.fancylibrary",
    ...
}
```

Resources.json File

The `Resources.json` file lists all resources in a component or library folder. It resides next to each `manifest.json` in the generated results.

The file is generated during build time and its main purpose is for mobile packaging, as `resources.json` mentions all files inside the application. If an app has a `resources.json` file, it is mentioned in the `manifest.json` under `sap.app/resources`.

> **i Note**
>
> This file is used by SAP Tools like the SAP Fiori Client Packager. It will be generated automatically when using SAP WebIDE.

The list of resources is stored in an array in the `resources` property of the top level JSON object. The top level object can also contain the `_version` property, which can be omitted if the value is `1.0.0`. For each resource, the following entries are possible:

Property	Type	Description
`name`	`string`	Relative path of the resource as accessible in a server; starts with the first name segment, for example `Component.js` (mandatory)
`isDebug`	`Boolean`	When set to `true`, the resource is a debug source, the SAPUI5 build derives the flag from the naming convention (`-dbg(.controller .view .fragment).js`) (optional)
`locale`	`string`	Locale of the resource for known i18n resources; the SAPUI5 build derives the locale from the naming convention (`*_[locale].properties`) (optional)
`raw`	`string`	Name of the corresponding resource in the raw (developer) language for known i18n resources; for `messagebundle.en.properties`, for example, the corresponding raw file is `messagebundle.properties` (optional)
`merged`	`boolean`	Indicates whether the resource is a merged resource (optional)

Property	Type	Description
		By default, the SAPUI5 build determines this from naming conventions (`library-preload.json`, `library-all.js`, `Component-preload.js`), but it also allows to add more merged files by manual configuration of the build step. SAP Web IDE may use other knowledge for this; it knows, for example, that it merges the `Component-preload.js`.
`theme`	`string`	Indicates a theme-dependant resource (optional) The SAPUI5 build determines this from the naming convention `**themes<theme>/ **`

Example

```
{
    "resources":[
        {
            "name": ".library"
        },
        {
            "name": ".theming"
        },
        {
            "name": "DynamicSideContent-dbg.js",
            "isDebug":true
        },
        {
            "name": "DynamicSideContent.js"
        },
        {
            "name": "DynamicSideContentRenderer-dbg.js",
            "isDebug":true
        },

        ...

        {
            "name": "library-preload.json",
            "merged":true
        },

        ...

        {
            "name": "messagebundle_de.properties",
```

```
            "raw":"messagebundle.properties",
            "locale":"de"
        },

        ...

        {
            "name": "themes/sap_belize/library.less",
            "theme":"sap_belize"
        }

        ...

    ]
}
```

Creating a Descriptor File for Existing Apps

Detailed description of the steps needed to create a descriptor V2 for applications file for an existing transactional app created by the customer based on SAP Fiori.

1. Create the `manifest.json` file.
   You create the file in the web context root of your app on the same level as the `Component.js` file, using the content according to the instructions described from step 2 onwards. You can use the following code sample as a template. Make sure that you exchange or remove all placeholders (`<...>`) according to the instructions below.

   ```
   {
       "_version": "1.1.0",

       "start_url": "<startUrl>",

       "sap.app": {
           "_version": "1.1.0",
           "id": "<id>",
           "type": "application",
           "i18n": "<i18nPathRelativeToManifest>",
           "applicationVersion": {
               "version": "<version>"
           },
           "title": "{{<title>}}",
           "tags": {
               "keywords": [
                   "{{<keyword1>}}", "{{<keyword2>}}"
               ]
           },
           "dataSources": {
               "<dataSourceAlias>": {
                   "uri": "<uri>",
                   "settings": {
                       "localUri": "<localUri>"
                   }
               }
           }
       },
       "sap.ui": {
           "_version": "1.1.0",
           "icons": {
               "icon": "<icon>",
               "favIcon": "<favIcon>",
               "phone": "<phone>",
   ```

```
            "phone@2": "<phone@2>",
            "tablet": "<tablet>",
            "tablet@2": "<tablet@2>"
        },
        "deviceTypes": {
            "desktop": true,
            "tablet": true,
            "phone": true
        },
        "supportedThemes": [
            "sap_hcb",
            "sap_belize"
        ]
    },
    "sap.ui5": {
        "_version": "1.1.0",
        "resources": {
            "js": [
                {
                    "uri": "<uri>"
                }
            ],
            "css": [
                {
                    "uri": "<uri>",
                    "id": "<id>"
                }
            ]
        },
        "dependencies": {
            "minUI5Version": "<minUI5Version>",
            "libs": {
                "<ui5lib1>": {
                    "minVersion": "<minVersion1>"
                },
                "<ui5lib2>": {
                    "minVersion": "<minVersion2>"
                }
            },
            "components": {
                "<ui5component1>": {
                    "minVersion": "<minComp1Version>"
                }
            }
        },
        "models": {
            "i18n": {
                "type": "sap.ui.model.resource.ResourceModel",
                "uri": "<uriRelativeToManifest>"
            },
            "": {
                "dataSource": "<dataSourceAlias>",
                "settings": {}
            }
        },
        "rootView": "<rootView>",
        "handleValidation": <true|false>,
        "config": {

        },
        "routing": {

        },
        "extends": {
            "component" : "<extendedComponentId>",
            "minVersion": "<minComp1Version>",
            "extensions": {}
        }
```

```
        "contentDensities": {
            "compact": <true|false>,
            "cozy": <true|false>
        }
    },
    "sap.platform.abap": {
        "_version": "1.1.0",
        "uri": "<uri>"
    },
    "sap.platform.hcp": {
        "_version": "1.1.0",
        "uri": "<uri>"
    }
}
```

2. Fill the `start_url` (W3C namespace).
   If applicable, replace the `<start_url>` placeholder with the start URL of your app, for example `index.html`. If no start URL is shipped, remove the `"start_url"` section in the `manifest.json` file.

```
{
    "start_url": "index.html",
    ...
}
```

3. Fill the `id` and `applicationVersion/version` attributes of the `sap.app` namespace.

> ⚠ Caution
>
> `id` in the `sap.app` namespace must correspond to the component name in the `Component.js` file, for example `jQuery.sap.declare("cust.emp.myleaverequests.Component");`.

   To fill the ID and version information, open the `Component.js` file of your app and add the ID / namespace and version information:

```
jQuery.sap.declare("cust.emp.myleaverequests.Component");
...
    metadata :  {
        "name" : "My Leave Requests",
        "version" : "1.2.6"
```

   Open the `manifest.json` file and enter the values from the `Component.js` file as follows:

   - Replace the `<id>` placeholder with the the id / namespace value from `jQuery.sap.declare ("cust.emp.myleaverequests.Component"` in the example above).
   - Replace the `<version>` placeholder with the `version` value (`"1.2.6"` in the example above).

   Example: `sap.app/id` **and** `sap.app/applicationVersion/version` **in the** `manifest.json` **file**:

```
"sap.app": {
    "_version": "1.1.0",
    ...
    "id": "cust.emp.myleaverequests",
    ...
    "applicationVersion": {
        "version": "1.2.6"
    },
```

4. Fill the `i18n` and `title` attributes of the `sap.app` namespace.
   You find the respective information in the `Component.js` file under `resourceBundle` for the `i18n` attribute, and under `titleResource` for the `title` attribute:

```
"config" : {
```

```
    "titleResource": "app.Identity",
    "resourceBundle": "i18n/i18n.properties",
```

Open the `manifest.json` file and enter the values from the `Component.js` file as follows:

- Replace the `<title>` placeholder with the `titleResource` value (`"app.Identity"` in the example above)
- Replace the `<i18nPathRelativeToManifest>` placeholder with the `resourceBundle` value (`"i18n/i18n.properties"` in the example above).

Example: `sap.app/i18n` **and** `sap.app/title` **in the** `manifest.json` **file**

```
"sap.app": {
    "_version": "1.1.0",
    ...
    "i18n": "i18n/i18n.properties",
    ...
    "title": "{{app.Identity}}",
```

5. Fill the `tags/keywords` attribute of the `sap.app` namespace.
   If you maintain keywords for the SAP Fiori launchpad tile configuration (optional), enter one or more text symbols from the `sap.app/i18n` file in the `keywords` attribute of the `manifest.json` file. If not, remove the tags/keywords section from the `manifest.json` file.
   Example: `sap.app/tags/keywords` **in the** `manifest.json` **file**

```
"sap.app": {
    "_version": "1.1.0",
    ...
    "tags": {
        "keywords": [
            "{{Leave}}"
        ]
    },
```

6. Fill the `dataSource` attribute of the `sap.app` namespace with the data source you use for your app.
   For this, open the location where the service URL and the mock data source is defined.
   - Open the `Component.js` file of your app to see the data source under `serviceUrl`, see the following example for `name`, `serviceUrl` and mock data URL in `Component.js`:

```
metadata : {
    ...
    "config" : {
        ...
        "serviceConfig" : {
            name: "LEAVEREQUEST",
            serviceUrl: "/sap/opu/odata/GBHCM/LEAVEREQUEST;v=2/"
        }
    },
...

init : function() {
    ...
        oMockServer.simulate(rootPath + "/model/metadata.xml", rootPath +
"/model/");
```

   Return to the `manifest.json` file and do the following:
   - Enter the `name` value in the placeholder for `<dataSourceAlias>`.
   - Enter the value from the `serviceUrl` in the placeholder for `<uri>` to fill the value for the URI attribute.

- Enter the value from the URI of `oMockServer.simulate...` in the `Component.js` file in the placeholder for `<localUri>` to fill the value for the `localUri` attribute.

Example: `dataSources` **with alias and URI in the** `sap.app` **namespace of the** `manifest.json` **file**

```
"sap.app": {
    "_version": "1.1.0",
    ...
    "dataSources": {
        "LEAVEREQUEST": {
            "uri": "/sap/opu/odata/GBHCM/LEAVEREQUEST;v=2/",
            "settings": {
                "localUri": "model/metadata.xml"
            }
        }
    }
```

7. Fill the `icons` attribute of the `sap.ui` namespace.
   Open the `Component.js` file of your app to see the `icons` in the `config` section.
   Example: `icons` **in the** `Component.js` **file:**

```
"config" : {
    ...
    "icon": "sap-icon://Fiori2/F0394",
    "favIcon": "./resources/sap/ca/ui/themes/base/img/favicon/
My_Leave_Requests.ico",
    "homeScreenIconPhone": "./resources/sap/ca/ui/themes/base/img/launchicon/
My_Leave_Requests/57_iPhone_Desktop_Launch.png",
    "homeScreenIconPhone@2": "./resources/sap/ca/ui/themes/base/img/
launchicon/My_Leave_Requests/114_iPhone-Retina_Web_Clip.png",
    "homeScreenIconTablet": "./resources/sap/ca/ui/themes/base/img/launchicon/
My_Leave_Requests/72_iPad_Desktop_Launch.png",
    "homeScreenIconTablet@2": "./resources/sap/ca/ui/themes/base/img/
launchicon/My_Leave_Requests/144_iPad_Retina_Web_Clip.png"
},
```

   Return to the `manifest.json` file:
   - Enter the `icon` value in the `<icon>` placeholder.
   - Enter the `favIcon` value in the `<favIcon>` placeholder.
   - Enter the `homeScreenIconPhone` value in the `<phone>` placeholder. Do the same for the `<phone@2>`, `<tablet>` and `<tablet@2>` placeholders.

   Example: `icons` **in the** `sap.ui` **namespace of the** `manifest.json` **file**

```
"sap.ui": {
    "_version": "1.1.0",
    ...
    "icons": {
        "icon": "sap-icon://Fiori2/F0394",
        "favIcon": "./resources/sap/ca/ui/themes/base/img/favicon/
My_Leave_Requests.ico",
        "phone": "./resources/sap/ca/ui/themes/base/img/launchicon/
My_Leave_Requests/57_iPhone_Desktop_Launch.png",
        "phone@2": "./resources/sap/ca/ui/themes/base/img/launchicon/
My_Leave_Requests/114_iPhone-Retina_Web_Clip.png",
        "tablet": "./resources/sap/ca/ui/themes/base/img/launchicon/
My_Leave_Requests/72_iPad_Desktop_Launch.png",
        "tablet@2": "./resources/sap/ca/ui/themes/base/img/launchicon/
My_Leave_Requests/144_iPad_Retina_Web_Clip.png"
    },
```

   If your app does not have icons, remove the icons section or the corresponding icon attributes from the `manifest.json` file.

8. Fill the `deviceTypes` and `supportedThemes` attributes in the `sap.ui` namespace in the `manifest.json` file.
   Return to the `manifest.json` file and ensure that the `deviceTypes` and `supportedThemes` attributes in the `manifest.json` are correct for your application. If not, adapt the entries accordingly.
   Example: `deviceTypes` **and** `supportedThemes` **in the** `sap.ui` **namespace in the** `manifest.json` **file**

```
"sap.ui": {
    "_version": "1.1.0",
    ...
    "deviceTypes": {
        "desktop": true,
        "tablet": true,
        "phone": true
    },
    "supportedThemes": [
        "sap_hcb",
        "sap_belize"
    ]
```

9. Fill the `resources` attribute in the `sap.ui5` namespace.
   Open the `Component.js` file of your app to see the js and CSS resources under `includes`.
   Example: `includes` **in the** `Component.js` **file**

```
"includes": ["css/shopStyles.css", "myfile.js"],
```

   Return to the `manifest.json` file:
   - Enter the js resource value under `"js"` in the `<uri>` placeholder.
   - Enter the CSS resource value under `"css"` in the `<uri>` placeholder.

> ⚠ Caution
>
> The format in the `Component.js` file is an array, whereas the format in the `manifest.json` file is a map.

   Example: `resources` **attribute in the** `sap.ui` **namespace in the** `manifest.json` **file**

```
"sap.ui5": {
    "_version": "1.1.0",
    ...
    "resources": {
        "js": [
            {
                "uri": "myfile.js"
            }
        ],
        "css": [
            {
                "uri": "css/shopStyles.css"
            }
        ]
    },
```

   If your app does not include resources, remove the `resources` section from the `manifest.json` file.
10. Fill the `dependecies` attribute of the `sap.ui5` namespace with the SAPUI5 dependencies that are used.
    Open the `Component.js` file of your app to see the dependencies for the `ui5` libs and components.
    Example: `dependencies` **in the** `Component.js` **file**

```
"dependencies": {
    "libs": [
```

```
        "sap.m",
        "sap.me"
    ],
    "components": ["sap.app.otherComponent"]
}
```

Return to the `manifest.json` file and fill the corresponding entries in the `manifest.json`. Enter a value for the minimum SAPUI5 version in the `<ui5Version>` placeholder.

> ⚠ Caution
>
> The format in the `Component.js` file is an array, whereas the format in the `manifest.json` file is a map. Ensure that **all** of the SAPUI5 libraries used by your app are mentioned under libs. Also make sure that all of the SAPUI5 components used by your app are mentioned under `components`. If there are no dependent components, remove the `components` entry.

Example: `dependencies` **in the** `sap.ui5` **namespace in the** `manifest.json` **file**

```
"sap.ui5": {
    "_version": "1.1.0",
    ...
    "dependencies": {
        "minUI5Version": "1.30",
        "libs": {
            "sap.m": {
                "minVersion": "1.30"
            },
            "sap.me": {
                "minVersion": "1.30"
            }
        },
        "components": {
            "sap.app.otherComponent": {
                "minVersion": "1.2.0"
            }
        }
    },
```

If your app requires a minimum version of a lib or component, specify the version under `minVersion` for information purposes. If not, remove the `minVersion` attribute.

11. Fill the `models` attribute of the `sap.ui5` namespace.
    If a `model` is entered in `sap.ui5/models` in the `manifest.json` file, SAPUI5 creates the model automatically and the coding for model creation inside the app can be removed.
    Example: `model` **creation in** `Component.js`**:**

```
init : function() {
    ...
    // set i18n model
    var i18nModel = new sap.ui.model.resource.ResourceModel({
        bundleUrl : rootPath + "/i18n/i18n.properties"
    });
    this.setModel(i18nModel, "i18n");

    // set data model
    var m = new sap.ui.model.odata.v2.ODataModel(sServiceUrl);
    this.setModel(m);
```

    Return to the `manifest.json` file:
    - i18n model

Use the same model name as in the `Component.js` file, for example "i18n", and the type `sap.ui.model.resource.ResourceModel`. Enter the URI from the `Component.js` file in the `<uriRelativeToManifest>` placeholder relative to `manifest.json`, for example, `i18n/i18n.properties`

- OData model
  Use the same model name as in the `Component.js` file, for example "leave" or "" for the default model. Enter a reference to a data source from `sap.app/dataSource` in the `<dataSourceAlias>` placeholder; if needed, enhance it with more settings for SAPUI5.

Example: Models in the `sap.ui5` namespace in the `manifest.json` file

```
"sap.ui5": {
    "_version": "1.1.0",
    ...
    "models": {
        "i18n": {
            "type": "sap.ui.model.resource.ResourceModel",
            "uri": "i18n/i18n.properties"
        },
        "": {
            "dataSource": "LEAVEREQUEST",
            "settings": {
            }
        }
    },
```

12. Fill the `rootView`, `handleValidation`, `config` and `routing` attributes in the `sap.ui5` namespace.
    Open the `Component.js` file of your app to see the `rootView`, `handleValidation`, `routing`, `config` in the component metadata section.
    Example: `rootView`, `handleValidation`, `config`, `routing` in `sap.ui5` namespace of the `manifest.json` file:

    ```
    ...
    "rootView": "myRootView",
    "handleValidation": true,
    "config": {
        ...
    },
    "routing": {
        ...
    }
    ```

    Return to the `manifest.json` file and copy this metadata from the `Component.js` file to the `sap.ui5` namespace in the `manifest.json` file.
    Only transfer those config parameters in the `config` section to the `manifest.json` file that have not yet been transferred in the steps before. In other words, do not transfer `resourceBundle`, `titleResource`, `icon`, `favicon`, `homeScreenIconPhone`, `homeScreenIconPhone2`, `homeScreenIconTablet` and `homeScreenIconTablet2`.
    Example: `rootView`, `handleValidation`, `config` and `routing` in the `sap.ui5` namespace of the `manifest.json` file

    ```
    "sap.ui5": {
        "_version": "1.1.0",
        ...
        "rootView": "myRootView",
        "handleValidation": true,
        "config": {
            ...
        },
    ```

```
    "routing": {
        ...
    },
```

If there is no corresponding entry in the `Component.js` file, remove the section in the `manifest.json` file.

13. Fill the `extends` attribute of the `sap.ui5` namespace.
    Open the `Component.js` file of your app to see the component which your app extends:

```
hcm.emp.myleaverequests.Component.extend("cust.emp.myleaverequests.Component",
 {
```

Return to the `manifest.json` file and enter the value from the `component` namespace in the `<extendedComponentId>` placeholder, for example `hcm.emp.myleaverequests`.
Example: `extends/component` **in** `sap.ui5` **namespace in** `manifest.json` **file**

```
"sap.ui5": {
    "_version": "1.1.0",
    ...
    "extends": {
        "component": "hcm.emp.myleaverequests",
        "minVersion": "1.1.0"
    }
```

If your app requires a minimum version of a component, specify the version under `minVersion` for information purposes, otherwise remove the attribute. If your app uses the SAPUI5 extension concept with a `customizing` entry under component metadata in the `Component.js` file, move the content of that entry to `sap.ui5/extends/extensions` in the `manifest.json` file, or remove the `customizing` entry. If your app does **not** extend another component, remove the `extends` section from the `manifest.json` file.

14. Fill the `contentDensities` attribute of the `sap.ui5` namespace.
    Enter the correct values for the `compact` and `cozy` attributes (`true` or `false`) under `contentDensities` in the `manifest.json` file. The attributes specify the content density modes that your app supports, see Content Densities [page 1142].
    Example: `contentDensities` **in** `sap.ui5` **namespace of the** `manifest.json` **file:**

```
"sap.ui5": {
    "_version": "1.1.0",
    ...
    "contentDensities": {
        "compact": true,
        "cozy": true
    }
```

15. Verify that **no** placeholders exist.
    Return to the `manifest.json` file and make sure there are **no more** placeholders within it (`<...>`). If the file still contains placeholders, remove the corresponding sections.

Code Changes

1. Adapt the `Component.js` file.
   Example: `Component.js` **before making changes**

```
jQuery.sap.declare("cust.emp.myleaverequests.Component");
jQuery.sap.require("cust.emp.myleaverequests.Configuration");

hcm.emp.myleaverequests.Component.extend("cust.emp.myleaverequests.Component",
 {
    metadata :  {
        "name" : "My Leave Requests",
        "version" : "...",
        "library" : "cust.emp.myleaverequests",
        "includes" : [],
        "dependencies" : {
            "libs" : ["sap.m", "sap.me"],
            "components" : ["sap.app.otherComponent"]
        },
        "rootView": ...,
        "handleValidation": ...,
        "config": {
            ...
        },
        "routing": {
            ...
        },
        "config" : {
            "titleResource": "app.Identity",
            "resourceBundle": "i18n/i18n.properties",
            "icon": "sap-icon://Fiori2/F0394",
            "favIcon": "./resources/sap/ca/ui/themes/base/img/favicon/
My_Leave_Requests.ico",
            "homeScreenIconPhone": "./resources/sap/ca/ui/themes/base/img/
launchicon/My_Leave_Requests/57_iPhone_Desktop_Launch.png",
            "homeScreenIconPhone@2": "./resources/sap/ca/ui/themes/base/img/
launchicon/My_Leave_Requests/114_iPhone-Retina_Web_Clip.png",
            "homeScreenIconTablet": "./resources/sap/ca/ui/themes/base/img/
launchicon/My_Leave_Requests/72_iPad_Desktop_Launch.png",
            "homeScreenIconTablet@2": "./resources/sap/ca/ui/themes/base/img/
launchicon/My_Leave_Requests/144_iPad_Retina_Web_Clip.png"
        });
        });
```

Apply the following changes:

- Comment or remove the line for the `require` statement for configuration (if available) `sap.ui.require("cust.emp.myleaverequests.Configuration");`
- Add the manifest reference to the metadata: `"manifest": "json"`.
- Remove the `name` section.
- Remove the `library` section.
- Remove the `version` section.
- Remove the `includes` section.
- Remove the `dependencies` section.
- Remove the `rootView` section.
- Remove the `handleValidation` section.
- Remove the `routing` section.
- Remove the `config` section.

Example: `Component.js` **after making changes**

```
jQuery.sap.declare("cust.emp.myleaverequests.Component");
//jQuery.sap.require("cust.emp.myleaverequests.Configuration");

hcm.emp.myleaverequests.Component.extend("cust.emp.myleaverequests.Component",
 {
    metadata : {
```

```
        "manifest": "json",
        ...
});
```

2. Adapt the data source reference in the `Component.js` file.
   Example: Data source reference in `Component.js` file before making changes

```
metadata : {
    ...
    "config" : {
        ...
        "serviceConfig" : {
            name: "LEAVEREQUEST",
            serviceUrl: "/sap/opu/odata/GBHCM/LEAVEREQUEST;v=2/"
        }
    },
...

init : function() {
    ...
    var oServiceConfig = this.getMetadata().getConfig()["serviceConfig"];
    var sServiceUrl = oServiceConfig.serviceUrl;
    ...
    oMockServer.simulate(rootPath + "/model/metadata.xml", rootPath + "/
model/");
```

   Apply the following changes:
   - Remove `serviceConfig` under `config` in the component metadata.
   - If you are still using the service URL in your coding for purposes other than model creation, change the lines for getting the service config / url and read the URI from the manifest via your component metadata, for example, `this.getMetadata().getManifestEntry("sap.app")...`; otherwise, remove that coding.
   - Change the line for `oMockServer.simulate...` and read the URI from the manifest via your component metadata, for example, `this.getMetadata().getManifestEntry("sap.app")...`

   Example: Data source reference in `Component.js` file after making changes

```
metadata : {
    "manifest": "json",
    ...

init : function() {
    ...
    var sServiceUrl =
this.getMetadata().getManifestEntry("sap.app").dataSources["LEAVEREQUEST"].uri
;
    ...
    oMockServer.simulate(rootPath + "/" +
this.getMetadata().getManifestEntry("sap.app").dataSources["LEAVEREQUEST"].set
tings.localUri, rootPath + "/model/");
```

3. Remove the SAPUI5 model creation in the `Component.js` file.
   Example: `Component.js` file before making changes

```
init : function() {
    ...
    // set i18n model
    var i18nModel = new sap.ui.model.resource.ResourceModel({
        bundleUrl : rootPath + "/i18n/i18n.properties"
    });
    this.setModel(i18nModel, "i18n");

    // set data model
```

```
    var m = new sap.ui.model.odata.v2.ODataModel(sServiceUrl);
    this.setModel(m);
```

Apply the following changes:

- Delete the lines for the i18n model creation and model setting.
- Delete the lines for the data model creation and model setting.

Smoke Test

To verify that your app works as before, perform checks to make sure the following is true:

- OData service works as before
- Mock data works as before
- Title, icons in SAP Fiori launchpad work as before
- Navigation works as before

Migration Information for Upgrading the Descriptor File

Information how to add new attributes of descriptor versions higher than V2 (SAPUI5 1.30) to the descriptor file.

Attribute	Version*	Description	Example
`_version`	V3 (1.32)	Needs to be updated in the `manifest.json` file when migrating to a new descriptor version: • `_version` for V3 is 1.2.0 • `_version` for V4 is 1.3.0 • `_version` for V5 is 1.4.0 (see example)	`{ "_version": "1.4.0", "sap.app": { ...`
`sap.app/ crossNavigation`	V3 (1.32)	Contains navigation information and is a mandatory attribute in the `manifest.json` file for SAP Fiori apps; the attribute contains two sections: • `sap.app/ crossNavigation/ inbounds` - Contains	

Attribute	Version*	Description	Example
		inbound intents and signature information • `sap.app/crossNavigation/outbounds` - Contains required intents that are called explicitely by the app, for example, if a business process is split among different apps A and B. If A calls B, A has outbound the intent to address B.	
`sap.app/subTitle`	V4 (1.34)	Added to the `manifest.json` file by using the `{{...}}` syntax **i Note** Text symbols must be part of the properties file which is defined in `sap.app/i18n` (default `"i18n/i18n.properties"`) .	`"sap.app": { "_version": "1.3.0", ... "title": "{{title}}", "subTitle": "{{subtitle}}",`
`sap.app/crossNavigation/inbounds/<inboundname>/subTitle`	V4 (1.34)	Used to overwrite the `subTitle` attribute per inbound; use the `{{...}}` syntax to add the attribute to the `manifest.json` file **i Note** Text symbols must be part of the properties file which is defined in `sap.app/i18n` (default `"i18n/i18n.properties"`) .	`"sap.app": { "_version": "1.3.0", ... "crossNavigation" : { "inbounds": { "contactCreate": { "semanticObject": "Contact", "action": "create", "icon": "sap-icon://add-contact",`

Attribute	Version*	Description	Example

			<pre>"title": "{{title}}",
			
			"subTitle": "{{subtitleOther}}",</pre>

sap.ui/fullWidth	V4 (1.34)	Indicates whether an app shall run in full screen mode (true)	<pre>"sap.ui": {
			"_version": "1.3.0",
			
			"technology": "UI5",
			...
			"fullWidth": true</pre>

sap.ui5/dependencies/components/<componentname>/lazy and dependencies/libs/<libname>/lazy	V4 (1.34)	If dependencies/components/<componentname>/lazy and dependencies/libs/<libname>/lazy are set to true, the attribute indicates in an SAP Fiori app that a dependency shall be lazy loaded (default is false), see the example for manifest.json for the SAP Fiori app.	Example for manifest.json for the SAP Fiori app:
			<pre>"sap.ui5": {
			"_version": "1.2.0",
			...
			
			"dependencies": {
			
			"minUI5Version": "1.34.0",
			"libs": {
			
			"sap.m": {
			
			"minVersion": "1.34.0"
			},
			
			"sap.ui.commons": {
			
			"minVersion": "1.34.0",
			
			"lazy": true
			}
			},
			
			"components": {
			
			"sap.ui.app.other": {
			
			"minVersion": "1.1.0"
			
			"lazy": true
			}</pre>

Attribute	Version*	Description	Example
			} },

sapui5/routing/config/async	V4 (1.34)	General setting for routing that indicates how the views are loaded; if set to true, the views are loaded asynchronously (default is false)
		
		For performance reasons, we recommend to always use the async setting. This recommendation implies that you have followed the SAPUI5 programming model in general and do **not** rely on any sync-execution depending event-orders.
			"sap.ui5": {
			"_version": "1.2.0",
			...
			"routing": {
			
			"config": {
			
			"viewType": "XML",
			
			"async": true
			...
			},
			...

sap.ui5/models/preload	V5 (1.38)	Defines whether or not the model is initialized (preloaded) before the component instance is created and while loading the component preload and its dependencies	"equipment": {
			"preload": true,
			
			"dataSource": "equipment",
			...
			}

* Available as of descriptor version (SAPUI5 version)

Descriptor Dependencies to Libraries and Components

Description of the performance-relevant attributes that are available for the descriptor for applications, components and libraries

The performance-relevant attributes have been introduced with the version 3 of the descriptor for applications, components, and libraries.

Dependencies to Libraries

The following dependencies to libraries can be implemented:

- To benefit from the asynchronous library preload, add the mandatory libraries to sap.ui5/dependencies/libs.

- To expose the necessary dependencies for offline packages for mobile devices, add optional libraries to `sap.ui5/dependencies/libs` and flag them as `lazy`.

For **applications and components**, modify the `manifest.json` as follows:

```
"sap.ui5": {
    ...
    "dependencies": {
      ...
      "libs": {
        "sap.m": {},
        "sap.suite.ui.commons": {
          "lazy": true
        }
      }
      ...
    },
    ...
```

For **libraries**, modify the `.library` file as shown in the follown code sample. This file is available because the `manifest.json` for libraries is generated based on this metadata.

```
<dependencies>
    <dependency>
       <libraryName>sap.m</libraryName>
    </dependency>
    <dependency>
       <libraryName>sap.suite.ui.commons</libraryName>
       <lazy>true</lazy>
    </dependency>
    ...
```

In a second step, modify the `library.js` file as follows:

```
sap.ui.getCore().initLibrary({
   ...
   dependencies : ["sap.ui.core","sap.m"], // lazy libs are not declared here
```

ℹ Note

In all cases, the lazy libraries need to be loaded manually in the application or library via the `loadLibrary` API:

```
// lazy lib loaded synchronously (avoid if possible!)
sap.ui.getCore().loadLibrary("sap.suite.ui.commons");
// lazy lib loaded asynchronously (the preferred way!)
sap.ui.getCore().loadLibrary("sap.suite.ui.commons", { async:
true }).then(...);
```

→ Tip

Execute the `loadLibrary` before any resource of the library is required to preload the complete library instead of loading each resource individually.

Always use the async API as this is the preferred and performant way. Only use the sync API as an exception if your coding relies on synchronous loading.

Dependencies to Components

Scenario 1: UI library contains multiple components

In this scenario, the library is the leading container and **no** component preload is available. This means, that you maintain the library dependency as described above. This is true for all kinds of component dependencies, also for `sap.ui5/extends/component`. If the extended component originates in a library, do **not** use `sap.ui5.extends/component`, but only declare the library dependency. Otherwise, the component dependency causes a 404 request.

For loading lazy components inside a library, proceed with the library mechanisms as described above:

```
// lazy lib loaded synchronously (avoid if possible!)
sap.ui.getCore().loadLibrary("sap.suite.ui.commons");
// lazy lib loaded asynchronously (the preferred way!!!)
sap.ui.getCore().loadLibrary("sap.suite.ui.commons", { async: true }).then(...);
```

Scenario 2: Standalone component

In this scenario, you only maintain a dependency to the component. The component preload is available for this scenario:

- To benefit from the asynchronous components preload, add the mandatory components to `sap.ui5/dependencies/components`
- Add the **optional** components to `sap.ui5/dependencies/components` and flag them as `lazy`.

For applications and components, modify the `manifest.json` as follows:

```
"sap.ui5": {
    ...
    "dependencies": {
      ...
      "libs": {
        ...
      },
      "components": {
        "samples.components.sample": {},
        "samples.components.samplelazy": {
          "lazy": true
        }
        ...
      }
    },
    ...
```

For loading/instantiating the lazy standalone components, use the component factory functions:

```
// "Component" required from module "sap/ui/core/Component"
// Asynchronously loads a component class without instantiating it.
Component.load({
  name: "..."
}).then(function(ComponentClass) {
  ...
});
// Asynchronously creates a new component instance from the given configuration.
// If necessary the component class is loaded.
Component.create({
  name: "..."
}).then(function(oComponentInstance) {
  ...
});
```

Manifest Model Preload

The `preload` flag enables a preload mode for a model, thus improving the startup performance of an app or component.

The `preload` flag is located in `manifest.json` under `sap.ui5/models`:

```
"sap.ui5": {
  ...
  "models": {
      "mymodel": {
          "preload": true,
          ...
```

The flag is not active by default, as there are some prerequisites:

- `sap.ui.component` is set to `"async=true"` and `manifest` (API parameter name of `sap.ui.component`).
- `Model` implementation class is loaded before `sap.ui.component` is called; otherwise the model will not be created.
- As model events (for example `attachMetadataLoaded`) may be missed because they are fired before the component coding runs, we recommend using the `Promise` API (e.g. `metadataLoaded`) instead, depending on the model type.
- Use the model preload flag for `sap.ui.model.resource.ResourceModel` if one of the following applies:
  - There is no component preload.
  - The corresponding resource files are not part of the component preload.

This means: The preload flag only makes sense for models which load their data from other locations than the component itself. Local JSON, XML or resource model does not make sense as it interferes with the component preload which will result in loading the model data twice and should be omitted. But for the V2 OData model, for example, using preload speeds up the performance as the OData metadata can already be loaded in parallel to the component preload.

Before enabling the preload for the V2 ODataModel, make sure that you listen properly to metadata loaded by using the `Promise` API instead of the `Event` API (`metadataLoaded`) since the preload could have loaded the metadata already before the application code is executed. The Promise will be executed even if the metadata loaded event has been raised already.

Listen properly to metadata loaded by using the Promise:

```
oModel.metadataLoaded().then(function() {  /* TODO: add the event handling here!
*/  });
```

Enabling the Automatic SAP Fiori 2.0 Header Adaptation in the Descriptor

Application developers can enable automatic adaptation of their existing applications from the manifest.json app descriptor. This helps to easily convert applications to the new look-and-feel of SAP Fiori 2.0.

SAP Fiori 2.0

SAP Fiori 2.0 is the next evolution step of the SAP Fiori UX. SAP Fiori 2.0 features new themes, a more unified user experience, and smoother, more intuitive application interactions.

Application headers, written based on older SAP Fiori design guidelines, can now be easily adapted to the new SAP Fiori 2.0 look-and-feel by using the automatic adaptation mechanism in the app descriptor.

The SAP Fiori 2.0 Header

The SAP Fiori 2.0 design concept requires changes with regards to the headers of applications and the SAP Fiori launchpad (FLP). If your application has a header, it needs to be merged into the standardized SAP Fiori 2.0 header. SAPUI5 offers an adapter mechanism to let existing apps automatically adjust their header layout according to the SAP Fiori 2.0 guidelines.

> **i Note**
>
> The screenshots in this topic are mockups and are used to visually outline the adaptations. The final apps will look somewhat different.

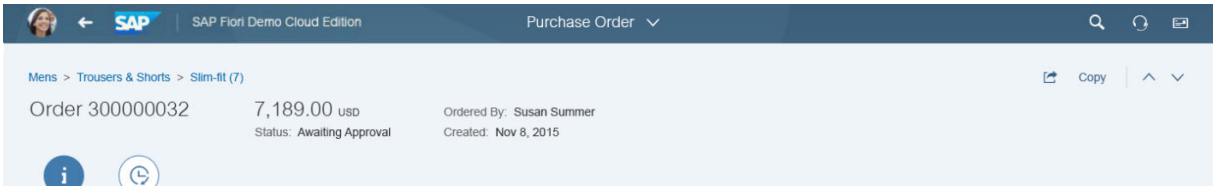

Figure 210: SAP Fiori 2.0 header of a fullscreen application

The complete adaptation of a fullscreen app to SAP Fiori 2.0 consists of five main steps:

1. Remove the app-specific header bar. The header is made transparent and collapsed if there is no content in it after the adaptation.
2. Display the title in the center of the FLP header
3. Move the action buttons from the app header to the header content area below the FLP header.
4. Move the *Back* button from the app-specific header to the FLP header.
5. Drill-down hierarchy levels can be added to the dropdown menu adjacent to the FLP title.

You can see how the elements are moved and transformed from the old SAP Fiori version (below) to the new SAP Fiori 2.0 design in the screenshot below.

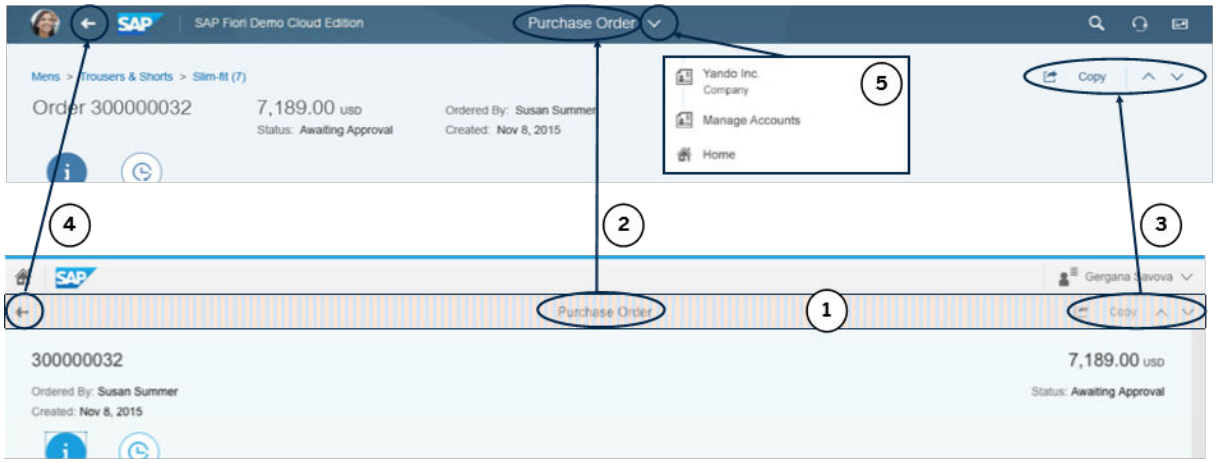

Figure 211: SAP Fiori 2.0 header adaptation

> **i** Note
>
> These adaptations are primarily valid only for **fullscreen** apps. Other floorplans, like Master-Detail, are affected differently and the adaptation there will not be the same.

Enabling the Adaptation in the App Descriptor

You can override the adapter default behavior for a single application by adding an entry in the app descriptor in the `sap.ui5/config` section. Setting `sapFiori2Adaptation` to **true** enables the full functionality of the SAP Fiori 2.0 Adapter.

```
"config": {
            ...
            "sapFiori2Adaptation": true,
            ...
}
```

Alternatively, you can use five fine-grained settings to enable only some of the adaptations. In the following example, you can see how to trigger transparent headers (`style` attribute) and title propagation to FLP (`title` attribute). The other adaptations are not applied.

```
"config": {
            ...
            "sapFiori2Adaptation": {
                  "style": true,
                  "collapse": false,
                  "title": true,
                  "back": false,
                  "hierarchy": false
            },
            ...
}
```

In the list below, you can see what each of the settings enables.

- `style` - Triggers header transparency

- `collapse` - Triggers collapsing of the header when empty
- `title` - Triggers moving the header to FLP
- `back` - Triggers the *Back* button visibility in the app
- `hierarchy` - Triggers propagation of the hierarchy to FLP

> **i** Note
>
> In rare cases this automatic adaptation of the header area may not work, due to the application structure or other reasons. In this case the headers will still appear in the old design, but the apps will continue to be usable.

Some old SAP Fiori applications do not have an app descriptor yet. If you consider the effort to provide proper app descriptors for all applications as too high, there is a second way to do this configuration. This alternative configuration is done in the `metadata` section of **`Component.js`** (the app's root component), which also has a `config` section. The configuration options can be done there in the same manner.

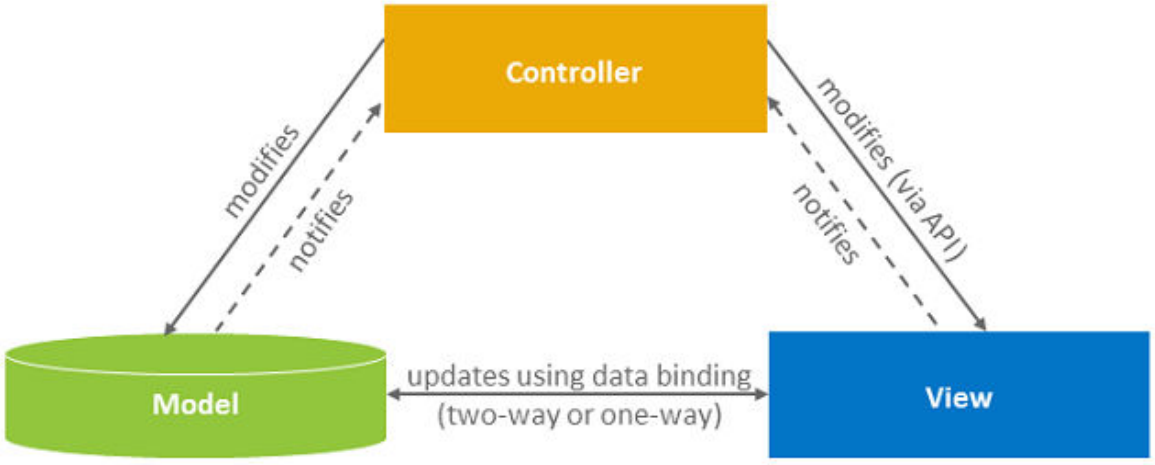
> **i** Note
>
> If both the metadata and manifest are configured, and contradict each other, the configuration in **manifest.json** is applied.

Model View Controller (MVC)

The Model View Controller (MVC) concept is used in SAPUI5 to separate the representation of information from the user interaction. This separation facilitates development and the changing of parts independently.

Model, view, and controller are assigned the following roles:

- The **view** is responsible for defining and rendering the UI.
- The **model** manages the application data.
- The **controller** reacts to view events and user interaction by modifying the view and model.



- Models [page 882]

- Controller [page 807]
- Views [page 787]

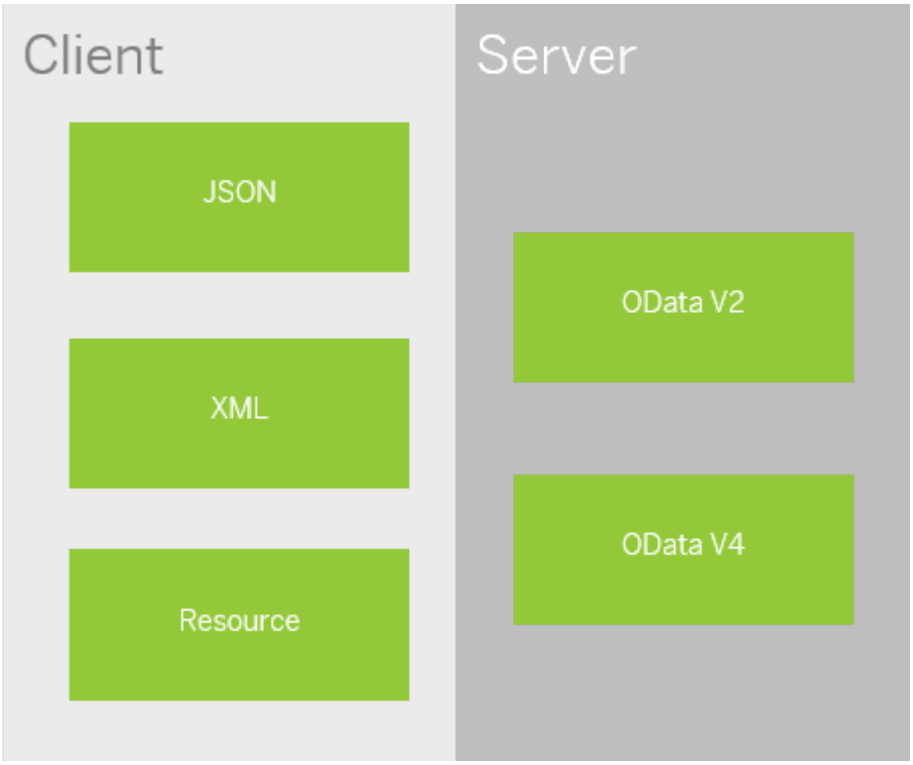
The purpose of data binding in the UI is to separate the definition of the user interface (view), the data visualized by the application (model), and the code for the business logic for processing the data (controller). The separation has the following advantages: It provides better readability, maintainability, and extensibility and it allows you to change the view without touching the underlying business logic and to define several views of the same data.

Views and controllers often form a 1:1 relationship, but it is also possible to have controllers without a UI, these controllers are called application controllers. It is also possible to create views without controllers. From a technical position, a view is a SAPUI5 control and can have or inherit a SAPUI5 model.

View and controller represent reusable units, and distributed development is highly supported.

Models

A model in the Model View Controller concept holds the data and provides methods to retrieve the data from the database and to set and update data.



- JSON Model [page 991]
- XML Model [page 993]
- Resource Model [page 995]

- OData V2 Model [page 883]
- OData V4 Model [page 918]

SAPUI5 provides the following predefined models:

- **OData model**: Enables binding of controls to data from OData services. The OData model supports two-way, one-way and one-time binding modes. However, two-way binding is currently only supported for properties, and not for aggregations.

  > **i** Note
  >
  > The OData model currently supports the following OData versions:
  >
  > - OData V2
  > - OData V4 (limited feature scope)

- **JSON model**: Can be used to bind controls to JavaScript object data, which is usually serialized in the JSON format. The JSON model is a client-side model and, therefore, intended for small data sets, which are completely available on the client. The JSON model supports two-way (default), one-way and one-time binding modes.
- **XML model**: A client-side model intended for small data sets, which are completely available on the client. The XML model does not contain mechanisms for server-based paging or loading of deltas. The XML model supports two-way (default), one-way and one-time binding modes.
- **Resource model**: Designed to handle data in resource bundles, mainly to provide texts in different languages. The resource model only supports one-time binding mode because it deals with static texts only.

The JSON model, XML model, and the resource model are **client-side models**, meaning that the model data is loaded completely and is available on the client. Operations such as sorting and filtering are executed on the client without further server requests.

The OData (V2 or V4) model is a **server-side model** and only loads the data requested by the user interface from the server.

You can not only define one model for your applications, but define different areas in your application with different models and assign single controls to a model. You can also define nested models, for example, a JSON model defined for the application and an OData model for a table control contained in the application.

A Web application should support several data sources, such as JSON, XML, Atom, or OData. However, the way in which data binding is defined and implemented within the UI controls should be independent of the respective data source. It is also possible to create a custom model implementation for data sources that are not yet covered by the framework or are domain-specific.

Related Information

API Reference: `sap.ui.model`

Views

The view in the Model View Controller concept is responsible for defining and rendering the UI. SAPUI5 supports predefined view types.

The following predefined view types are available:

- **XML view** (file or string in XML format); the `XMLView` type supports a mix of XML and plain HTML.
- **JSON view** (file or string in JSON format)
- **JS view**, constructed in a traditional manner
- **HTML view** (file or string in HTML format)

> **i** Note
>
> We recommend to use XML views, because XML views force a clear separation of the UI definition from the application logic (which has to be implemented in the controller). This makes the code more readable and easier to support.
>
> Therefore, we concentrate on XML views and only provide examples for XML views throughout this documentation.

Related Information

API Reference

XML View

The XML view type is defined in an XML file. The file name either ends with `.view.xml` or as an XML string. The file name and the folder structure together specify the name of the view that equals the SAPUI5 module name.

> **✤** Example
>
> For `resources/sap/hcm/Address.view.xml`, the view name is `sap.hcm.Address`. The application uses this view name for displaying an instance of this view. If you define the XML view by means of an XML string, no file or define/require is needed.
>
> The file looks as follows:

```
<mvc:View controllerName="sap.hcm.Address" xmlns="sap.m"
xmlns:mvc="sap.ui.core.mvc">
   <Panel>
      <Image src="http://www.sap.com/global/ui/images/global/sap-logo.png"/>
      <Button text="Press Me!"/>
   </Panel>
</mvc:View>
```

Nest the XML tags analogous to the nesting sequence of SAPUI5 controls and add the property values as attributes (see Namespaces in XML Views [page 788]).

Each control or element is represented by an XML tag with the name the control. If you, for example, want to create an instance of a `sap.m.Button`, you use tag `<Button>` with namespace `sap.m`. You can create a context binding for the control by using attribute `objectBinding` or `Binding`. For more information, see Context Binding (Element Binding) [page 824].

Related Information

API Reference: `sap.ui.html.xmlview`

Namespaces in XML Views

The names of the SAPUI5 control libraries and the related subpackages are mapped to XML namespaces.

One of the required namespaces can be defined as the default namespace (`xmlns="..."`). The control tags for this namespace do not need a prefix.

The `View` tag is required and in the example below, the `sap.ui.core.mvc` namespace is defined with alias `mvc`. Technically, you can define any alias for namespaces. However, the convention is to use the last part of the full package name.

A control can be located in a subpackage of a control library, for example `sap.ui.layout.form.Form` is located in the `sap.ui.layout` library, but the full package name is `sap.ui.layout.form`. You have to specify this subpackage as a separate XML namespace, even if `sap.ui.layout` is already defined as namespace.

```
<mvc:View
     xmlns:mvc="sap.ui.core.mvc"
     xmlns:layout="sap.ui.layout"
     xmlns:form="sap.ui.layout.form"
     xmlns="sap.m">
</mvc:View>
```

Aggregation Handling in XML Views

In XML views, aggregated child controls can be added as child tags.

Aggregations of XML Views

On root level, you can only define content for the default aggregation, e.g. without adding the `content` tag. If you want to specify content for another aggregation of a view like `dependents`, place it in a child control´s `dependents` aggregation or add it by using the `addDependent` method.

Aggregations of Controls Inside the View

Some controls have more than one content area, for example the shell control that has the main content area, a menu bar, a `headerItems` aggregation, a `worksetItems` aggregation, and so on. An aggregation tag usually serves as a direct child of a container and contains children. You can only add children directly if the container control has marked one of the child aggregations as default.

> **i Note**
>
> Some containers may not have default content, for example, the splitter container has two equally important content areas.
>
> The framework supports you by issuing error message in case of errors in the aggregation handling in XML views.

You fill aggregations as shown in the following example. The namespace of the parent control tag and the aggregation tag must be the same.

```
<mvc:View controllerName="sap.hcm.Address" xmlns="sap.m"
xmlns:mvc="sap.ui.core.mvc">
   <Panel>
      <content>  <!-- this is the general way of adding children: use the
aggregation name -->
         <Image src="http://www.sap.com/global/ui/images/global/sap-logo.png"/>
         <Button text="Press Me"/>
      </content>
   </Panel>
</mvc:View>
```

If an aggregation of **cardinality** `0..1` has an alternative type and if you want to specify a value of that alternative type, you have to do this as an attributes, not as a nested element.

> **Example**
>
> For the `noData` aggregation of the `sap.ui.comp.smarttable.SmartTable` control, you can either define a string or a nested text control.

String

```
<SmartTable noData="No data
available">
    ...
</SmartTable>
```

Nested text control

```
<SmartTable ....>
    <noData>
        <Text text="No data
available" icon="sap-icon://..." />
    </noData>
    ...
</SmartTable>
```

You can also use attributes to define binding information for aggregations with cardinality `0..n`. For more information, see *Declarative List Binding in XML Views* under List Binding (Aggregation Binding) [page 828].

Control Properties and Associations in XML Views

Properties

Property values for controls in XML views are specified as attributes of the XML element tag of the control. The name of the attribute corresponds to the name of the property in the API reference, for example, the property `text` of a the `sap.m.Button` control is specified as `text="value"`.

> **i** Note
>
> Escape characters that have a special meaning in XML (like `<`, or `&`) when they occur in a property value. Use XML entities instead (like `<` instead of a `<`, or `&` instead of `&`).

Attributes in XML views use the same binding syntax as constructors of controls. For example, `"{customerName}"` is used to bind a property against the model property with name `"customerName"`.

Associations

- Associations of **cardinality** `1`: Define the ID of the associated element in an attribute that has the same name as the association in the XML view.
- Associations of **cardinality** `0..n`: You can define multiple IDs separated by a blank.

Using Native HTML in XML Views

The use of native HTML in XML views depends on the XHTML feature set.

Context

When mixing XHTML and SAPUI5 controls, observe the following rules:

- XHTML elements can be used instead of the SAPUI5 type control, for example, in the root of an XML view or in the content aggregation of a layout container.
- When embedding XHTML in an aggregation of a SAPUI5 control, the XHTML must not consist of a single text node. The topmost node of an embedded XHTML tree must be an XHTML element. Embedding pure text into an aggregation is not supported.
- The XHTML nodes are converted 1:1 to HTML, the XML view does not deal with any differences between XHTML and HTML (for example rewriting and auto-closing tags)
- The created HTML DOM nodes are preserved during re-rendering of an XML view: Modifications to the DOM are not lost.

> **i** Note
>
> As an alternative to embedding XHTML, you can use the `sap.ui.core.HTML` control. As this requires content encoding it is, however, less convenient.

Procedure

To mix SAPUI5 controls with native XHTML, you only need the XHTML namespace to use (X)HTML:

```
<mvc:View controllerName="sap.hcm.Address" xmlns="sap.m"
xmlns:mvc="sap.ui.core.mvc"
          xmlns:html="http://www.w3.org/1999/xhtml">
   <Panel>
      <Button text="Press Me. I am an SAPUI5 Button"/>
      <html:button>No, press me. I am native HTML Button.</html:button>
   </Panel>
</mvc:View>
```

Using CSS Style Sheets in XML Views

Style sheets are included in XML views in the same way as plain HTML. To add further CSS classes to SAPUI5 controls, use the `class` attribute.

Context

The effect is the same as calling `myButton.addStyleClass(...)`.

> → Tip
>
> We recommend to carefully choose the elements that you style as the CSS always affects the whole page and is **not** restricted to the view.

Procedure

To add a style sheet, add the style definition.
To add a style class and define a button that uses it, add the following coding:

```
<mvc:View controllerName="sap.hcm.Address" xmlns="sap.m"
xmlns:mvc="sap.ui.core.mvc"
          xmlns:html="http://www.w3.org/1999/xhtml">
   <html:style>
      .mySuperRedButton {
         color: red;
```

```
      }
    </html:style>
    <Panel>
       <Button class="mySuperRedButton" text="Press Me"/>
    </Panel>
</mvc:View>
```

Handling Events in XML Views

XML views use event handlers as attributes: The attribute name is the event name, such as "press" for a button, and the attribute value is the event handler name.

Addressing the Event Handler

Depending on the syntax of its name, the event handler will be looked up by this name in different locations:

- Names starting with a dot ('.') are always assumed to represent a method in the controller. They are resolved by removing the leading dot and reading the property with the resulting name from the controller instance. These names are relative to the view/controller. For example, `press=".myLocalHandler"` is resolved by `attachPress(oController["myLocalHandler"], oController);`

  > **i Note**
  >
  > This syntax is by intention consistent to the complex binding syntax for formatter functions.

- Names defined in a `core:require` statement can be used to access static functions of the required modules. For example, `press= "Util.handler"` sets the static `handler` function of the required `Util` module as press handler for the respective control. For more information, see Require Modules in XML View and Fragment [page 799].
- Names containing a dot at a later position are assumed to represent:
  - Static functions from the modules which are loaded through the XML view required modules (See Require Modules in XML View and Fragment [page 799])
  - Global functions if the function cannot be resolved within the XML view require modules and are resolved by calling `ObjectPath.get` with the full name. For example, `name press= "some.global.handler"` is resolved by calling `attachPress(ObjectPath.get("some.global.handler"), oController);`.

    > **i Note**
    >
    > The use of globals is not recommended and they should be replaced, see Require Modules in XML View and Fragment [page 799].

- Names without dot are interpreted as a relative name; if nothing is found, they are interpreted as an absolute name. This variant is only supported for backward compatibility.

> **i Note**
>
> When specified without parameters, the event handler will be called with one argument, the event object. This object can be used to retrieve the event parameters documented by the control's respective event documentation.

The `"this"` Context

As long as no event handler parameters are specified and regardless of where the function was looked up, it will be executed with the controller as the context object (`this`). This is also true for global event handlers and makes the implementation of generic global handlers easier that may need an easy way back to the controller/ view in which they are actually used, for example, to call `createId` or `byId`. This should make the development of global event handlers more consistent with controller local event handlers.

Therefore, the following declaration is equivalent to a call of `controller.doSomething()` when the button is pressed:

```
<Button text="Press Me" press=".doSomething"/>
```

However, once event parameters are specified using the syntax described below, the `this` context is always the object on which the handler function is defined. For controller methods, the controller remains the `this` context, but for methods defined in the XML view required modules or on global objects, that owner object is used as `this` context. In case the controller is still required in such global handler functions, it can be explicitly passed as `$controller` parameter (see the *Passing Parameters* section below). Functions defined directly on the XML view required modules or on the `window` object have an undefined `this` context.

By invoking the special JavaScript function `.call(...)` on your event handler function, you can also provide a different `this` context. For example, you can still have the controller as `this` in an event handler in a global helper object, even when you pass parameters, by doing:

```
<Button core:require="{Helper:'path/to/Helper'}" text="Press Me"
press="Helper.doSomething.call($controller, 'Hello World')"/>
```

Passing Parameters

In XMLViews and JSONViews it is also possible to directly specify the parameters that should be passed into the event handler function. These parameters then are passed instead of the event object. The syntax mimics the JavaScript syntax for function calls:

```
<Button text="Press Me" press=".doSomething('Hello World')"/>
```

Any JavaScript literals including objects and arrays can be passed:

```
<Button text="Press Me" press=".doSomething('string', 0, 5.5, {key1: 'value1',
key2: 'value2'}, ['value1', 'value2'])"/>
```

It is also possible to access model properties. The syntax to be used is the one used within Expression Binding – binding paths are enclosed in **${...}** :

```
<Button text="Press Me" press=".doSomething(${products>unitPrice})"/>
```

The binding context from which relative binding paths are resolved is the context of the control which triggers the event. This means that for a control in a table row, relative binding paths like the one above, always pass the data from the table row where the event occurred. This is very convenient, because it is no longer required to find out the data element to which the table row is bound.

Complex binding syntax can also be used (to add formatters, types etc.), as well as all expressions allowed by Expression Binding [page 845]:

```
<Button text="Press Me" press=".doSomething(${path: 'products>unitPrice',
formatter: '.formatPrice'})" />
<Button text="Press Me" press=".doSomething(10 * ${products>unitPrice})" />
<Button text="Press Me" press=".doSomething(${products>type} === 'Laptop')" />
```

! Restriction

Even though complex bindings can have multiple parts (use multiple data properties) instead of just one data property path, this is not possible for the event parameters. Therefore, you cannot use `parts` in bindings.

Formatters are resolved the same way as the event handlers: a leading dot means the formatter is member of the controller.

i Note

While it seems like regular JavaScript can be written directly in the event handler specification, this is not the case. The entire expression is evaluated as expression binding and only the syntax elements allowed there can be used.

There are two special named models available in event handlers to make accessing certain values easier:

The first one is named `$parameters` and contains the event parameters:

```
<Select change=".doSomething(${$parameters>/selectedItem})" />
```

Here the event parameter `selectedItem` is passed into the event handler.

The other one is named `$source` and is a `ManagedObjectModel` which wraps the control firing the event:

```
<Button text="Press Me" press=".doSomething(${$source>/text})" />
```

Here the text of the pressed button is passed into the event handler.

There are also two special values which can be used as parameters.

The first special value is named `$event` and represents the original event object. This event object is no longer passed to event handlers, once parameters are specified. This is because of the `$parameters` model, which provides access to the event parameters, and it is not needed in most cases. However, when access to the event object is still needed in the event handler, it can be explicitly passed:

```
<Button text="Press Me" press=".doSomething($event)" />
```

This leads to the same result as specifying `.doSomething` without any parameters, but further parameters can of course be given.

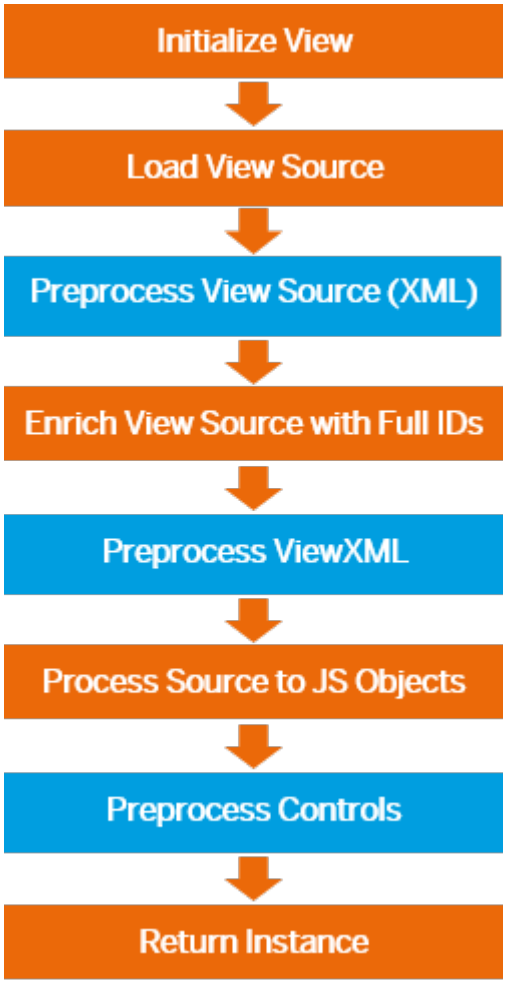
The second special value is `$controller`. As described above, as soon as parameters are specified, the `this` context inside the event handler function is always the object on which this function is defined. However, sometimes it is still required to access the controller even in a handler function which is NOT defined in the controller, but on some other helper object. In this case, the controller can be explicitly passed as one of the parameters:

```
<Button text="Press Me" press=".doSomething($controller)" />
```

Preprocessing XML Views

Applying preprocessing to views enables you to use features like XML templating. This feature is currently only enabled for XML views. On an abstract level, preprocessing means that a view can be modified during runtime before it is rendered. This makes it possible to use the templating syntax, as it is interpreted by the preprocessor. It also makes it possible to apply user customization.

The following figure shows the different stages of view initialization. There are three hooks, XML, ViewXML and controls, which differ mainly in the source that is passed to the preprocessor.



- XML
  The raw view source in the XML format is passed to the preprocessor. This enables example templating on XML level.
- ViewXML
  The raw view source with all XML preprocessing results gets enhanced with its full IDs for the controls and passed on to the preprocessor. Adaptions on a valid view source can now be made before the XML is being parsed into a control tree.
- Controls
  The view source is already processed to the JavaScript object and the control tree is available. This enables you to make changes to the view after design time, like special customizations, stored at some persistence layer or similar, the user has made previously. Or customizations depending on the user role which are not applicable during design time.

For preprocessor for view sources of type XML or ViewXML which create cacheable results, see VML View Cache: Preprocessor Integration [page 798].

Using the Preprocessor

First, you need a preprocessor implementation. SAPUI5 provides a default preprocessor for XML templating which can be enabled by default. You can also build your own preprocessor based on the `Preprocessor` interface. For more information, see the API Reference and the sample in the Demo Kit.

To use the preprocessor, you can choose one of the following options:

- Global availability
  Makes the preprocessor available to all XML views and processes it every time a View is initialized. This maybe the right case for essential operations you want to apply to every view in your application. Therefore you can make use of the `registerPreprocessor` method:

  ```
  // "XMLView" required from module "sap/ui/core/mvc/XMLView"
  XMLView.registerPreprocessor("xml", "sap.ui.sample.samplepreprocessor",
  /* bSyncSupport = */ false, {sampleInfo: "this is a global preprocessor",
  moreInfo: "…"});
  ```

  For more information, see API Reference: `sap.ui.core.mvc.XMLView.registerPreprocessor`.
- Local availability
  Make a preprocessor available to one instance. This can be achieved by passing the preprocessor to the view factory function, which then processes it for this special instance. This would be the choice for smaller tasks the preprocessor should perform.

  ```
  // "XMLView" required from module "sap/ui/core/mvc/XMLView"
  XMLView.create({
         viewName: "sap.ui.core.sample.View.preprocessor.Sample",
         preprocessors: {
                xml: [{
                      preprocessor: "sap.ui.sample.samplepreprocessor",
                      sampleInfo: "this is a local preprocessor",
                      moreInfo: "…"
                },
                {
                      preprocessor: "another.preprocessor"
                }]
         }
  }).then(function(oView) {
  ```

```
        oView.doSomething();
});
```

- On demand availability
  This enables the developer to activate a preprocessor for a view instance, without the need to provide an implementation, by just specifying a preprocessor, which has been registered globally earlier. This is currently used by the XML templating.

> **i Note**
>
> Preprocessors are per default only available for async views. Although it is possible to enable the preprocessor for sync views, we strongly recommend to only use them with async views.

> **i Note**
>
> The information that is provided when using a preprocessor locally will be passed to the preprocessor according to the `mSettings` of the register method.

Related Information

XML View Cache [page 797]

XML View Cache

To be able to speed up processing times of XML views that make heavy use of the preprocessor feature, you can use the view cache to store its processed XML source. Then according network requests for the source and all preprocessor runs that modify the XML source are skipped and the source is taken from the cache.

To make sure that the cache always contains the latest view data, the cache has to be invalidated whenever the data changes that is needed for preprocessing. When the cache is invalidated, all resources are processed again and the cache gets filled with new data.

> **⚠ Caution**
>
> Parts of this feature are currently still experimental. For more information, see API Reference: `sap.ui.xmlview`.

The following data changes are handled automatically by SAPUI5:

- SAPUI5 version changes
- Descriptor file (`manifest.json`)
- Locale (for each locale one cached resource is being created)

> **i Note**
>
> For each additional component that may have an influence on the preprocessing results of the view source, like OData metadata, you have to implement the invalidation by adding additional keys to the cache configuration.

Prerequisites

This feature is only enabled for the following browsers:

- Google Chrome as of version 49 for desktop
- Internet Explorer as of version 11 for desktop

The XML view has to be loaded asynchronously.

Cache Configuration

If you want to keep things simple, you can use the following cache configuration:

```
var sCalculatedCacheKey = oKeyProvider.getCacheKey();
sap.ui.xmlview({
    async: true,
    id: "cacheableView",
    viewName: "my.cacheableView",
    cache: {
        // one key is mandatory
        keys:[sCalculatedCacheKey]
    }
});
```

If you want to pass on multiple keys, for example strings or promises that resolve with a string, you use the following syntax:

```
var pCalculatedCacheKey = oKeyProvider1.getCacheKeyPromise();
var sAnotherKey = oKeyProvider2.getCacheKey();
sap.ui.xmlview({
    async: true,
    id: "cacheableView",
    viewName: "my.cacheableView",
    cache: {
        keys: [
        // several key providers, at least one
        pCalculatedCacheKeyPromise,
        sAnotherKey
        ]
    }
});
```

Preprocessor Integration

If you want to implement a preprocessor that has influence on the creation of views, for example, by changing the XML code, you can use function `getCacheKey`. With this function, the view can find out whether the preprocessor triggers changes that invalidate the cache. The function returns a cache key or a promise that resolves a cache key. For more information, see API Reference: `sap.ui.core.mvc.View.Preprocessor`.

```
// Example preprocessor implementation
sap.ui.define(['jquery.sap.global', 'sap/ui/base/Object'],
    function(jQuery, BaseObject) {
        'use strict';
```

```
        var TestPreprocessor = BaseObject.extend("smy.TestPreprocessor", {});
        TestPreprocessor.process = function(vSource, sCaller, mSettings) {
            return doSomething(vSource));
        };
        TestPreprocessor.getCacheKey = function(oViewInfo) {
            return sCacheKey;
        };
        return TestPreprocessor;
    }, /* bExport= */ true);
```

Preprocessing XML Views [page 795]

Require Modules in XML View and Fragment

Modules can be required in XML views and fragments and assigned to aliases which can be used as variables in properties, event handlers, and bindings.

The `require` attribute with namespace URI `sap.ui.core` can be used to define the module aliases and paths. In the following sections we assume that the namespace prefix `core` is used to define the URI `sap.ui.core` which makes the attribute to be written as `core:require`. This attribute can be used at every element of an XML view or fragment. You can specify a list of required modules as Unified Resource Names, similar to `sap.ui.require`, and assign aliases to them using a JSON-like syntax.

```
<mvc:View xmlns:core="sap.ui.core" xmlns:mvc="sap.ui.core.mvc"
   core:require="{
      Box: 'sap/m/MessageBox',
      Toast: 'sap/m/MessageToast'
   }">
   ...
</mvc:View>
```

> **i Note**
>
> The modules defined in the `core:require` attribute are loaded first before any other attributes of the element with `core:require` are processed. Therefore, they can be used in the same element for bindings, event handlers, and so on.

`core:require` can only handle static imports which require the module path to be defined by using a string literal. It is not possible to use a binding or an expression for defining the module path. As `core:require` is not interpreted as a binding expression, it is not necessary to escape the curly braces in `core:require` which is different than in the other attributes.

The aliases can then be used to access the modules' static functions. The alias is valid for the element where the alias is defined and the subtree of that element.

> **i Note**
>
> When you use the view in combination with fragments, keep in mind that the alias does not work in embedded fragments. In this case, define a separate `core:require` inside the fragments.

Example With Event Handler

You can use the XML `require` to reference static functions of a module which can serve as event handlers. This works with static strings as well as with any model data. For a description how this is done, see Handling Events in XML Views [page 792]. As the `Box` module is defined on the root element, it can be used in the whole view.

```
<mvc:View controllerName="some.Controller" xmlns="sap.m"
      xmlns:core="sap.ui.core" xmlns:mvc="sap.ui.core.mvc"
      core:require="{Box:'sap/m/MessageBox'}">
   <Panel>
      <Image src="http://www.sap.com/global/ui/images/global/sap-logo.png"/>
      <Button text="Press Me!" press="Box.show('Hello!')"/>
   </Panel>
</mvc:View>
```

> **i Note**
>
> `$controller`, `$event`, `$parameters`, and `$source` are reserved keywords for resolving an event handler. Avoid using these keywords as aliases for the required modules with `core:require`.

Example With Data Binding

You can also use the `require` module with data binding. Formatters and factory functions can be defined with the `require` modules, as well as expression bindings. The following code extract also shows, that the `Factory` module, which is defined on the List element, can only be used there, and not in sibling or parent controls:

```
<mvc:View controllerName="some.Controller" xmlns="sap.m"
      xmlns:core="sap.ui.core" xmlns:mvc="sap.ui.core.mvc"
      core:require="{Util:'some/Util'}">
  <Panel>
      <Image src="http://www.sap.com/global/ui/images/global/sap-logo.png"/>
      <Text text="{formatter: 'Util.format', path: '/text'}"/>
      <List core:require="{
              Factory:'some/Factory'
          }" id="list" items="{path:'/items', factory:'Factory.createItem'}">
      </List>
   </Panel>
</mvc:View>
```

`core:require` in Fragments

`core:require` can be used in fragments and set on every element, including `FragmentDefinition`. However, `core:require` on `FragmentDefinition` node does not have any effect in the following use cases:

- The view where a fragment is used is preprocessed. For more information about preprocessing, see Preprocessing XML Views [page 795].
- A fragment is defined inline within a View.

```
<mvc:View controllerName="some.Controller" xmlns="sap.m"
      xmlns:core="sap.ui.core" xmlns:mvc="sap.ui.core.mvc">
  <FragmentDefinition>
      <!-- core:require can't be defined on the above FragmentDefinition -->
      ...
  </FragmentDefinition>
  ...
</mvc:View>
```

`core:require` does not work as expected in both of the above use cases because the `FragmentDefinition` node is **not** part of the resulting view. Therefore, the module information which is defined in the `core:require` on `FragmentDefinition` node is not available for its child nodes.

JSON View

The JSON view type is defined in a file. The file name has to either end with `.view.json` or as a JSON string. The file name and the folder structure together specify the name of the view that equals the SAPUI5 module name within the modularization concept.

For the file `resources/sap/hcm/Address.view.json`, the view name is `sap.hcm.Address`. The application uses this view name for displaying an instance of this view.

The file looks as follows:

```
{
   "Type":"sap.ui.core.mvc.JSONView",
   "controllerName":"sap.hcm.Address",
   "content": [{
      "Type":"sap.m.Image",
      "id":"MyImage",
      "src":"http://www.sap.com/global/ui/images/global/sap-logo.png"
   },
   {
      "Type":"sap.m.Button",
      "id":"MyButton",
      "text":"Press Me"
   }]
}
```

Nest the JSON objects analogous to the nesting of SAPUI5 controls and add the property values as attributes. The syntax is the same as the syntax of a JSON constructor for any control.

> **i Note**
>
> You can use strings, Boolean values, and null in your JSON view.

Aggregation Handling

You add child controls as arrays. This is shown in the example above where an image and a button have been added to the view content aggregation.

Event Handling

In JSON views, event handlers are bound as attributes with the attribute name as event name like `press` for a button and the attribute value as event handler name.

The following declaration causes `controller.doSomething()` to be executed when the button is pressed:

```
...
   {
      "Type":"sap.m.Button",
      "id":"MyButton",
      "text":"Press Me",
      "press":"doSomething"
   }
...
```

The location in which an event handler is looked up, are similar to XML views (see Handling Events in XML Views [page 792]).

Data Binding

You can bind data in JSON views. To bind the texts of a control to a language-dependent resource bundle, define the resource bundle via name (`resourceBundleName` property) or a URL (`resourceBundleUrl` property) and assign an alias (`resourceBundleAlias` property) for the bundle within the view definition. The binding path is the same for all other SAPUI5 data bindings.

Resource bundle content:

```
MY_TEXT=Hello World
```

Example

```
{   "Type": "sap.ui.core.JSONView",
    "controllerName":"my.own.views.test",
    "resourceBundleName":"myBundle",
    "resourceBundleAlias":"i18n",
    "content": [{
        "Type":"sap.m.Panel",
        "id":"myPanel",
        "content":[{
            "Type":"sap.m.Button",
            "id":"Button1",
            "text":"{i18n>MY_TEXT}",
            "press": "doIt"
        }]
    }]
}
```

The `ResourceModel` for binding this texts is created during view instantiation. The model is set as secondary model with the given alias to the view instance. To bind other properties to another model, create the model in the corresponding controller or HTML page and attach it to the view with another alias.

JS View

You create a JS (JavaScript) view in the same way as a controller and use the suffix `.view.js` for the file.

SAPUI5 provides the following two default methods for implementation:

- `getControllerName()`: Specifies the controller belonging to this view
  If this method is not implemented or returns `NULL`, the view has no controller.
- `createContent()`: Called initially once after the controller has been instantiated
  This method is used to create the UI. As the method knows the controller, it can directly attach the event handlers.

Example

```
   sap.ui.jsview("sap.hcm.Address", {  // this View file is called
Address.view.js

   getControllerName: function() {
      return "sap.hcm.Address";     // the Controller lives in
Address.controller.js
   },
   createContent: function(oController) {
      var oButton = new sap.m.Button({text:"Hello JS View"});
      oButton.attachPress(oController.handleButtonClicked);
      return oButton;
   }
});
```

The string in quotes denotes the view name that equals the SAPUI5 module name within the define/require concept.

Caution

In event handlers for controls "this" usually denotes the control itself. This is unexpected when it happens in event handlers that are implemented inside controllers: The controller would usually expected to be denoted as "this". This is no issue for declarative view types, but for JSViews the view developer may need to modify the "this" context as follows:

```
   ...
      oButton.attachPress(jQuery.proxy(oController.handleButtonClicked,
oController));
   ...
```

Alternatively, the view developer can give the event handler method in an array where the second element is the "this" object:

```
   ...
      var oButton = new sap.m.Button({
         text: "Hello JS View",
```

```
          press: [oController.handleButtonClicked, oController]
        });
    ...
```

⚠ Caution

If you want to define IDs for controls inside a JSView to guarantee their uniqueness when reusing views, you can **not** give hardcoded IDs, but have to give the view the opportunity to add its own instance ID as a prefix. This is done by using the `View.createId(...)` method. For the example above, this is done as follows:

```
var oButton = new sap.m.Button(this.createId("myButton"), {text:"Hello JS
View"});
```

This is not required for declarative view types as the view parser can manage this automatically, see Support for Unique IDs [page 814].

HTML View

An HTML View is defined by declarative HTML. Like the declarative support, the HTML view supports embedded HTML. The view file ends with `view.html`, for example `myview.view.html`.

Example

```
  <template data-controller-name="example.mvc.test">
   Hello
  <h1>Title</h1>
  <div>Embedded HTML</div>
  <div class="test test2 test3" data-sap-ui-type="sap.m.Panel" id="myPanel">
  <div class="test test2 test3" data-sap-ui-type="sap.m.Button" id="Button1"
data-text="Hello World" data-press="doIt"></div>
  <div data-sap-ui-type="sap.m.Button" id="Button2" data-text="Hello"></div>
  <div data-sap-ui-type="sap.ui.core.mvc.HTMLView" id="MyHTMLView" data-view-
name="example.mvc.test2"></div>
  <div data-sap-ui-type="sap.ui.core.mvc.JSView" id="MyJSView" data-view-
name="example.mvc.test2"></div>
  <div data-sap-ui-type="sap.ui.core.mvc.JSONView" id="MyJSONView" data-view-
name="example.mvc.test2"></div>
  <div data-sap-ui-type="sap.ui.core.mvc.XMLView" id="MyXMLView" data-view-
name="example.mvc.test2"></div>
  </div>
</template>
```

All view-specific properties can be added to the `<template>` tag as `data-*` attributes.

Related Information

Declarative Support [page 1057]

Instantiating Views

To instantiate views asychronously, SAPUI5 provides the factory method `View.create` defined in module `sap/ui/core/mvc/View`.

To pass the required information for the instantiation, use an object with the following properties:

- `type`: The type can be `JSON`, `JS`, `XML` or `HTML`. All possible types are declared in the enumeration `sap.ui.core.mvc.ViewType`.
- `viewName`: View name corresponding to the module concept
- `viewContent`: Only relevant for XML views and JSON views. Defines the XML or JSON string representation of the view definition. If `viewName` and `viewContent` are given, the `viewName` property is used to load the view definition.
- `Controller`: Any controller instance; the given controller instance overrides the controller defined in the view definition
- `viewData`: Only used for JS views; this property contains user-specific data that is available during the whole lifecycle of the view and the controller

All regular properties of a view (control) can be passed to the object as usual.

Loading Views

The default mode is the asynchronous loading of a view: The advantage of asynchronous loading compared to synchronous loading is that the UI does not freeze for the duration of the loading process and there is no blockage of functionalities during view initialization.

With the asynchronous loading of views, the instance is not fully available at the moment of creation, instead you may receive a `Promise` via the `View.prototype.loaded` method. The following code snippet shows how the view instance is available in the resolve function of the `promise`.

> **i** Note
>
> If you access the view in the controller's `onInit` callback, the view instance is available in any case. The behavior does not change.

```
// "View" required from "sap/ui/core/mvc/View"
// "coreLibrary" required from "sap/ui/core/library"
// "my.own.controller" was defined earlier
View.create({
    viewName: "my.own.view",
    controller: "my.own.controller",
    type: coreLibrary.mvc.ViewType.XML
}).then(function(oView) {
    // the instance is available in the callback function
    oView.placeAt("uiArea");
});
```

Synchronous Mode

> **i** Note
>
> We do **not** recommend this mode. Use the asynchronous mode instead.

The following code snippet creates a view instance, loads the view source, places the instance to the `uiArea`, and renders it later on.

```
var oController = sap.ui.controller("my.own.controller");
var oView = sap.ui.view({
    viewName: "my.own.view",
    controller: " my.own.controller",
    type: sap.ui.core.mvc.ViewType.XML
});
// the instance is available now
 oView.placeAt("uiArea");
...
```

Lazy Loading for XML Views

The following code snippet shows how to do a lazy loading for XML views:

```
<!-- File: view/CustomView.view.xml -->
<mvc:View xmlns="sap.m" xmlns:mvc="sap.ui.core.mvc">
    <Text text="Custom View loaded ..."/>
</mvc:View>
```

```
// File: controller/MainController.controller.js
sap.ui.require(["sap/ui/core/mvc/XMLView", "sap/ui/core/mvc/Controller"],
function(XMLView, Controller) {
    return Controller.extend("samples.controller.MainController", {
        // ...
        onSomeEventTriggered: function() {
            // instantiate view using create-factory
            XMLView.create({
                viewName: "samples.view.CustomView"
            })
            .then(function(oCustomView) {
                // View loaded ...
            })
        }
    });
 });
```

For an example, see the `sap.ui.core.sample.View.async/preview` sample in the Demo Kit.

View Cloning

For normal controls, view cloning bases on control settings that are described by SAPUI5 metadata, such as properties, aggregations, associations, and event handlers. The clone operation collects these settings and creates a new instance.

Another important aspect of SAPUI5 views is their cloning behavior. As you might know, SAPUI5 aggregation bindings can use template control to create a series of similar controls based on a collection of data, for example, items in a `RowRepeater` for each entry in a model array. The data binding uses a `ManagedObject.clone` operation to create multiple controls out of a single template.

For views there is a conflict between this basic, generic approach and the way how views usually define their content: via hooks (JSView) or via persisted XML or JSON files. Furthermore, it is allowed and documented

best practice to modify the view in the onInit hook of its controller. To avoid conflicts between the generic cloning and the MVC concepts, views implement a slightly modified clone operation: only a subset of the view settings are cloned, the remainder is re-created by calling the hook (JSView) or applying the external view description (XML or JSON file), depending on the view type.

Cloned in a generic way are the following settings:

- any models that have been set (`setModel()`)
- registered control event listeners (`attachSomeEvent`)
- registered browser event listeners (`attachBrowserEvent`)
- bindings (`bindProperty`, `bindAggregation`)

Not cloned, but recreated are all aggregations, namely the content.

In scenarios where the above clone approach still leads to undesirable behavior, factory functions can be used for the aggregation binding instead.

Related Information

List Binding (Aggregation Binding) [page 828]

Controller

A controller contains methods that define how models and views interact.

You define a simple controller as follows:

```
sap.ui.controller("sap.hcm.Address", {
   // controller logic goes here
});
```

The string in quotes specifies the controller name. The controller file's name should be named as the string in the quotes, `Address.controller.js`.

> **i Note**
>
> The suffix `.controller.js` is mandatory for controllers.

Lifecycle Hooks

SAPUI5 provides predefined lifecycle hooks for implementation. You can add event handlers or other functions to the controller and the controller can fire events, for which other controllers or entities can register.

SAPUI5 provides the following lifecycle hooks:

- `onInit()`: Called when a view is instantiated and its controls (if available) have already been created; used to modify the view before it is displayed to bind event handlers and do other one-time initialization

- `onExit()`: Called when the view is destroyed; used to free resources and finalize activities
- `onAfterRendering()`: Called when the view has been rendered, and therefore, its HTML is part of the document; used to do post-rendering manipulations of the HTML. SAPUI5 controls get this hook after being rendered.
- `onBeforeRendering()`: Called every time the view is rendered, before the renderer is called and the HTML is placed in the DOM tree.

> **i** Note
>
> For controllers without a view, no lifecycle hooks are called.

> **Example**
>
> ```
> sap.ui.controller("sap.hcm.Address", {
>    onInit: function() {
>       this.counter = 0;
>    }
> });
> ```

Event Handlers and Other Functions

In addition to lifecycle hooks, a controller can define additional methods that serve as event handlers or additional functionality offered by the controller.

> **Example**
>
> ```
> sap.ui.controller("sap.hcm.Address", {
>    increaseCounter: function() {
>       this.counter++;
>    }
> });
> ```

`Methods` Section in the Controller Metadata

By default, all methods that **do not** start with an underscore or with prefix "on", "init" or "exit" are public. You can get all public methods of a controller by using the `oController.getMetadata().getPublicMethods()` API.

When you use the new `methods` section in the controller metadata, only functions prefixed by "_" become private by default. In addition, you get the possibility to control the visibility, flag methods as final, or define an `overrideExecution` strategy. The same applies for the new controller extension metadata. This makes the definition of a public interface more flexible.

Only public methods and methods that are not flagged as final could be overridden by a controller extension.

Note

If you don't use the new `methods` definition for controllers, you could override the `onInit`, `onExit`, `onAfterRendering` and `onBeforeRendering` methods of the controller even if they are private by default.

The following sample code shows how to define an extension to an existing controller.

Example

Sample controller extension:

```
sap.ui.define(['sap/ui/core/mvc/Controller', 'sap/ui/core/mvc/
OverrideExecution'], function (Controller, OverrideExecution) {
    "use strict";
    return Controller.extend("sap.hcm.Address", {
        metadata: {
            // extension can declare the public methods
            // in general methods that start with "_" are private
            methods:{
                publicMethod: {public: true /*default*/, final: false /
*default*/, overrideExecution: OverrideExecution.Instead /*default*/},
                finalMethod: {final: true},
                onMyHook: {public: true /*default*/, final: false /
*default*/, overrideExecution: OverrideExecution.After},
                couldBePrivate: {public: false}
            }
        },
        // adding a private method, only accessible from this controller
        _privateMethod: function() {
        },
        // adding a public method, might be called from, but not overridden
by other controllers or controller extensions as well
        publicMethod: function() {
        },
        // adding a final method, might be called from, but not overridden by
other controllers or controller extensions as well
        finalMethod: function() {
        },
        // adding a hook method, might be called from, but not overridden by
a controller extension
        // override these method does not replace the implementation, but
executes after the original method
        onMyHook: function() {
        },
        // method public by default, but made private via metadata
        couldBePrivate: function() {
        }

    });
});
```

Controller Extensions Implementation Guidelines

All public methods need to stay compatible:

- Parameters of the method can be enhanced only with new optional parameters.
- It is recommended to use a JS object to pass the parameters. Extension can be done by adding an optional key, while working with parameters needs to stick to the sequence.

- Documentation should be maintained for all public methods.
- Use the `@since` version to tell the consumer on which version this method was introduced.

> **i Note**
>
> Within the methods of a controller extension, the reserved base member allows access to the public functions of the extended controller.
>
> Functionality can be called by using `this.base.basePublicMethod()`.

For more information on how to use controller extensions, see Using Controller Extension [page 810].

API Reference

sap.ui.core.mvc.Controller

Using Controller Extension

Controller extensions allow you to add functionality to existing applications. This can be used for extensibility purposes, for example a customer extending SAP-delivered applications, or as a reusable part that is added to the original application.

Overview

The following sample code shows how to define an extension for an existing controller.

```
sap.ui.define(['sap/ui/core/mvc/ControllerExtension', 'sap/ui/core/mvc/
OverrideExecution'], function(ControllerExtension, OverrideExecution) {
  "use strict";
  return ControllerExtension.extend("my.extension.SampleExtension", {
    metadata: {
      // extension can declare the public methods
      // in general methods that start with "_" are private
      methods: {
        publicMethod: {
          public: true /*default*/ ,
          final: false /*default*/ ,
          overrideExecution: OverrideExecution.Instead /*default*/
        },
        finalMethod: {
          final: true
        },
        onMyHook: {
          public: true /*default*/ ,
          final: false /*default*/ ,
          overrideExecution: OverrideExecution.After
        },
        couldBePrivate: {
          public: false
        }
```

```
      }
    },
    // adding a private method, only accessible from this controller extension
    _privateMethod: function() {},
    // adding a public method, might be called from or overridden by other
controller extensions as well
    publicMethod: function() {},
    // adding final public method, might be called from, but not overridden by
other controller extensions as well
    finalMethod: function() {},
    // adding a hook method, might be called from but not overridden by other
controller extensions
    // overriding these method does not replace the implementation, but executes
after the original method
    onMyHook: function() {},
    // method public by default, but made private via metadata
    couldBePrivate: function() {},
    // this section allows to extend lifecycle hooks or override public methods
of the base controller
    override: {
      // override onInit of base controller
      onInit: function() {},
      // override public method of the base controller
      basePublicMethod: function() {}
    }
  });
});
```

For more detailed information on lifecycle hooks and controller metadata, see Controller [page 807].

Custom Lifecycle Events

If you want to have additional lifecycle events like the standard `onInit` or `onExit` for developers extending the controller, you can define them as described in this section.

Controller extensions allow you to define custom lifecycle hooks. In the `Sample`, the `ReuseExtension.js` defines a custom lifecycle hook by specifying an `overrideExecution` function:

```
return ControllerExtension.extend("sap.my.ReuseExtension", {
        metadata: {
            methods: {
                "onFilterHook": {"public": true, "final": false,
overrideExecution: OverrideExecution.After}
            }
        },
        //...
        /**
         * @abstract
         */
        onFilterHook: function(aFilter) {
        }
    });
```

With `OverrideExecution.After`, the extensions are called in the order they are provided, with `OverrideExecution.Before` the order is reversed and the last extension is called first.

Final Methods in Controller Extensions

Adding `"final": true` metadata to the public method makes it available for execution (call) but not for overriding in the next controller extension.

```
return ControllerExtension.extend("sap.my.ReuseExtension", {
        metadata: {
            methods: {
```

```
                "myPublicMethod": {"public": true, "final": true}
            }
        },
        myPublicMethod: function() {
        }
    });
```

Accessing Controls in Controller Extensions

Only controls that belong to an extension are accessible by the `byId` function in a controller extension. These controls must be prefixed by the namespace of the controller extension. The namespace can be retrieved by calling `getMetadata().getNamespace()`. Here is an example of a valid ID: `my.controller.extension.MyControlId`.

Using the `byId` of the base controller allows the accessing of all controls of the corresponding view by calling `this.base.byId(myControlId)`.

Integrating Controller Extensions into Controllers

Controller extensions can serve for reuse purposes. You can achieve this by including a controller extension to your controller as a member.

```
sap.ui.define(['sap/ui/core/mvc/Controller', 'my/extension/SampleExtension'],
function(Controller, SampleExtension) {
    "use strict";
    return Controller.extend("sample.Main", {
        //include the extension
        sample: SampleExtension,

        _basePrivateMethod: function() {
            ...
        },
        basePublicMethod: function() {
     ...
    });
});
```

If the controller is instantiated, all members that have a `ControllerExtension` associated will create an instance of these controller extensions.

You can also override an extension directly in a controller.

Sample Code

```
sap.ui.define(['sap/ui/core/mvc/Controller', 'my/extension/SampleExtension'],
    function(Controller, SampleExtension) {
    "use strict";
    return MainController = Controller.extend("sample.Main", {
        //inline override of an extension. E.g. to provide a hook
implementation
        sample: SampleExtension.override({
            someHook: function() {},
            someOtherMethod: function() {}
        }),
        onLifecycleHook: function() {
        }
    });
});
```

File Names and Locations (View and Controller)

In SAPUI5, controllers and views are defined and instantiated via a name that equals an SAPUI5 module name within the define/require concept.

By default, all files have to be located in a subfolder of the `resources` folder of the Web application. If this location is not appropriate, deviations can be configured as described in the following example:

The following example assumes that your views and controllers are located on your local machine where the SAPUI5 runtime is loaded from another machine. When you instantiate a view or a controller, SAPUI5 runtime loads them in relation to the `resources` folder of the machine where SAPUI5 runtime was loaded. To inform SAPUI5 runtime that your views and controllers are located on your local machine, use the following code:

```
sap.ui.loader.config({
  paths: {
    "<moduleNamePrefix>": sUrl
  }
});
```

If your files are located at `http://<localhost:8080>/<myapp>/`, for example, you can use `sap.ui.loader.config` as follows:

```
sap.ui.loader.config({
  paths: {
    "my/app": "./myapp"
  }
});
```

All views and controllers with a name starting with `my.app`, for example `my.app.MyView`, will then be loaded from your local machine.

Folder Structure: Where to Put Your Files [page 1428]

Typed Views and Controllers

More complex use cases may require a more formal way to define views and controllers. For this, typed views and controllers are used.

To create a controller that is a new type of its own, you need to write a boilerplate code and declare the functions of the new prototype:

```
/* boilerplate code for typed Controller */
jQuery.sap.declare({modName:"sap.hcm.AddressController", type:"controller"}); //
declaring a special type of module
```

```
sap.hcm.AddressController = function () { // the constructor
   sap.ui.core.mvc.Controller.apply(this, arguments);
};
jQuery.sap.require("sap.ui.core.mvc.Controller"); // this is currently required,
as the Controller is not loaded by default
sap.hcm.AddressController.prototype =
jQuery.sap.newObject(sap.ui.core.mvc.Controller.prototype); // chain the
prototypes
/* end of boilerplate code for typed Controller */

// to avoid the above we could in the future offer it behind a simple call to:
// sap.ui.defineController("sap.hcm.Address");

sap.hcm.AddressController.prototype.onInit = function() {
   // modify control tree - this is the regular lifecycle hook
};

// implement an event handler in the Controller
sap.hcm.AddressController.prototype.doSomething = function() {
   alert("Hello World");
};
```

Support for Unique IDs

Stable IDs are used to identify and modify the controls within the controller during runtime. However, if you reuse or nest these views, these stable IDs are no longer unique. To avoid ambiguity, each view adds its own ID as prefix to all its child controls.

If the ID is created during instantiation of the control, it is unique by default. If you create further controls during runtime, the controller creates a unique ID by calling the `oController.createId("ID")` method. These methods add the necessary prefix to the ID.

If you want to modify the control with the ID `<ID>`, you can call the `byId(<ID>)` method on your view to get the correct control directly. You do not have to handle all the prefix stuff on your own.

The following view defines a button with the stable ID `aButton` (in the `ButtonView`):

```
<mvc:View viewName="sap.hcm.ButtonView" controllerName="sap.hcm.myController"
xmlns="sap.m" xmlns:mvc="sap.ui.core.mvc">
      <Button id="aButton" text="Click me"/><mvc:View>
```

The following view defines a view embedding the same view several times (`ContainerView`):

```
<mvc:View viewName="sap.hcm.ContainerView" controllerName="sap.hcm.Address"
xmlns="sap.ui.commons" xmlns:core="sap.ui.core"
           xmlns:html="http://www.w3.org/1999/xhtml">
      <mvc:View id="ButtonView1" viewName="sap.hcm.ButtonView"/>
      <mvc:View id="ButtonView2" viewName="sap.hcm.ButtonView"/>
<mvc:View>
```

The view is created as follows:

```
...
   // "View" required from module "sap/ui/core/mvc/View"
   View.create().then(function(oView) {/* code */});
...
```

The container view has the following IDs:

Both child view IDs have the prefix `myContainerView--`:

`myContainerView--ButtonView1`

`myContainerView--ButtonView2`

To get one of the child views, use the following code: Essentials [page 691]

```
...
var oButtonView1 = oView.byId("ButtonView1");
...
```

The button view has the following IDs:

`ButtonView1--aButton`

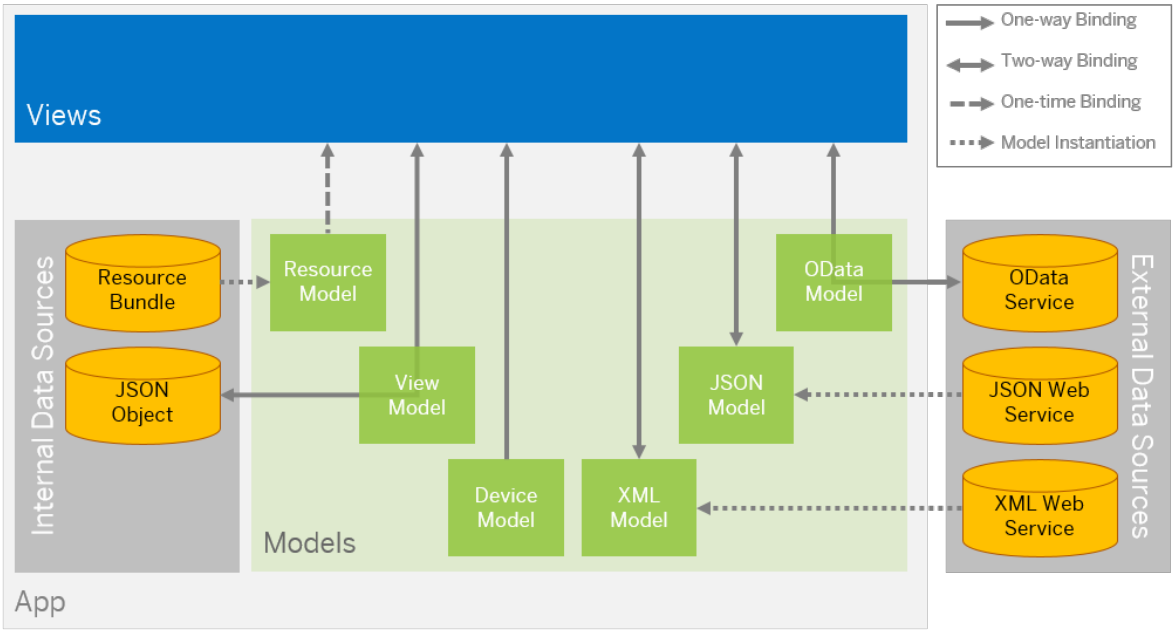
`ButtonView2--aButton`

To get the button control, use the following code:

```
...
   var oButton = oButtonView1.byId("aButton");
...
```

Data Binding

You use data binding to bind UI elements to data sources to keep the data in sync and allow data editing on the UI.



- Views [page 787]

- Models [page 882]
- Resource Bundles [page 1272]

SAPUI5 follows the "Model View Controller" (MVC) paradigm, which means that we clearly separate data sources (model), UI (view), and application logic (controller) from each other. Data binding defines how models and views communicate with each other.

Depending on which external data source you use, you can choose between different model types to represent it. SAPUI5 supports OData V4 (with restrictions), OData V2, JSON, and XML models.

There are also internal data sources that are defined in the app for specific purposes. For those, an app contains the following models:

- The **resource model** is used to communication with the resource bundle that contains translatable texts in multiple languages
- The **device model** is provided by the framework and defines device-specific settings
- **View models** can be, for example, JSON models that communicate with a corresponding JSON object. JSON data can also be edited in the app, but they are not stored - as soon as you refresh the browser or restart the app, the changes are reset.

Most of the models are client-side models. This means that all data is initially loaded to the model when the app is started. All actions performed on the data are only executed on the client, and only sent back to the data source when this is triggered by the app. Client-side models are therefore only recommended for small data sets.

The OData models (V2 and V4) are server-side models, which means that data is only requested on demand from the back end. Filtering, sorting, and paging actions are performed on the server. This means, for example, that you don't have to load a complete table on the UI to be able to sort the entries.

In the view, you bind data by specifying the **binding path** for a control. You can use **data types** and **formatters** to validate and format the data on the UI.

> **i** Note
>
> To learn more about data binding use the tutorial: Data Binding [page 219]

Binding Modes: One-time Binding, One-way Binding, and Two-way Binding

The binding mode defines how the data sources are bound. SAPUI5 provides the following binding modes:

- One-way binding means a binding from the model to the view; value changes in the model update all corresponding bindings and the view
- Two-way binding means a binding from the model to the view and from the view to the model, changes in the model and in the view fire events that automatically trigger updates all corresponding bindings and the view and model
- One-time binding means from model to view once.

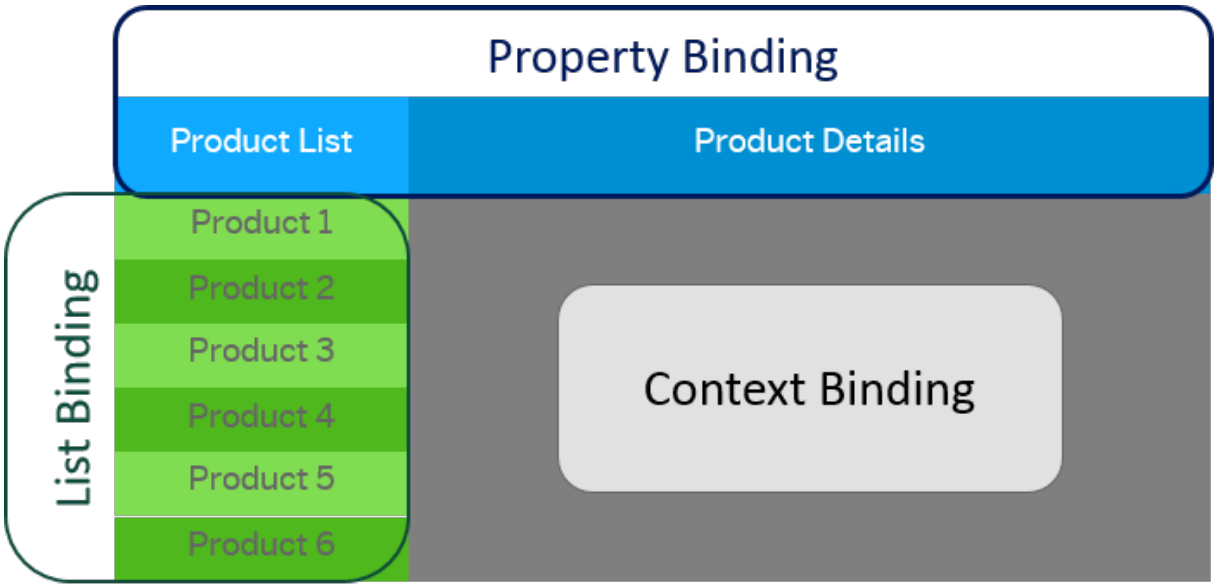
The following table shows which binding modes the respective binding models support:

Model	One-time	One-way	Two-way
OData V4 model	✓	✓	✓ (default)
OData V2 model	✓	✓ (default)	✓
ODataMetaModel V4	✓ (default)	✓	✗
ODataMetaModel	✓ (default)	✗	✗
JSON model	✓	✓	✓ (default)
XML model	✓	✓	✓ (default)
Resource model	✓	✓ (default)	✗

For more information, see API Reference: `sap.ui.model.BindingMode`.

Binding Types

Depending on the different use cases, you can use different binding types: Propety binding, context binding, and list binding.



- Property Binding [page 818]
- List Binding (Aggregation Binding) [page 828]

- Context Binding (Element Binding) [page 824]
- **Property binding** allows properties of the control to get automatically initialized and updated from model data. You can only bind control properties to model properties of a matching type, or you use a formatter or a data type to parse and convert the data as needed For more information, see Formatting, Parsing, and Validating Data [page 854].
- **Context binding** (or **"element binding"**) allows to bind elements to a specific object in the model that creates a binding context and allows relative binding within the control and all of its children. This is especially helpful in master-detail scenarios.
- **List binding** (or **"aggregation binding"**) can be used to automatically create child controls according to model. This can be done either by cloning a template control, or by using a factory function. Aggregations can only be bound to lists defined in the model, that is, to arrays in a JSON model or a collection in the OData model.

> **i** Note
>
> The model has a default size limit to avoid too much data being rendered on the UI. This size limit determines the number of entries used for the list bindings. The default size limit is 100 entries.
>
> This means that controls that don't support paging or don't request data in chunks (e.g. `sap.m.ComboBox`) only show 100 entries even though the model contains more items.
>
> To change this behavior, you can set a size limit in the model by using `oModel.setSizeLimit`.

Property Binding

With property binding, you can initialize properties of a control automatically and update them based on the data of the model.

To define property binding on a control, you have the following options:

- As part of the control's declaration in an XML view
- Using JavaScript, in the `settings` object in the constructor of a control, or in special cases, using the `bindProperty` method of a control

Once you have defined the property binding, the property is updated automatically every time the property value of the bound model is changed, and vice versa.

Let's say, we have the following JSON data:

```
{
"company" : {
        "name"   : "Acme Inc."
        "street": "23 Franklin St."
        "city"   : "Claremont"
        "state" : "New Hampshire"
        "zip"    : "03301"
        "revenue": "1833990"
          }
}
```

To define property binding in the control declaration in the **XML view**, just include the binding path within curly brackets (see also Binding Path [page 842]):

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Input
        value="{/company/name}"
    />
</mvc:View>
```

In **JavaScript**, you can include the binding path within curly brackets as a string literal in the `settings` object:

```
// "Input" required from module "sap/m/Input"
var oInput = new sap.m.Input({
    value: "{/company/name}"
});
```

You can also use a complex syntax for property bindings. This complex syntax allows you to define additional binding information to be contained in the `settings` object, such as a formatter function.

If you are working with **XML views**, make sure that you've turned on complex binding syntax in your bootstrap script, as shown here:

```
<script
       id="sap-ui-bootstrap"
      src="https://openui5.hana.ondemand.com/resources/sap-ui-core.js"
      data-sap-ui-theme="sap_belize"
     data-sap-ui-bindingSyntax="complex"
      data-sap-ui-async="true"
      data-sap-ui-onInit="module:sap/ui/sample/main"
       data-sap-ui-resourceRoots='{"sap.ui.sample": "./"}'
></script>
```

You can also use `data-sap-ui-compatVersion="edge"` to enable complex bindings.

You can then set the `bindingMode` or other additional properties like this:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Input
        value="{
            path:'/company/name',
            mode: 'sap.ui.model.BindingMode.OneWay'
        }"
    />
</mvc:View>
```

In **JavaScript** views or controllers, you use a JS object instead of a string literal. This must contain a `path` property containing the binding path, and can contain additional properties:

```
// "Input" required from module "sap/m/Input"
// "BindingMode" required from module "sap/ui/model/BindingMode"
var oInput = new Input ({
    value: {
        path: "/company/name",
        mode: BindingMode.OneWay
    }
});
```

Depending on the use case, it may be useful to define the binding at a later time, using the `bindProperty` method:

```
oInput.bindProperty("value", "/company/name");
```

This option also allows you to use the same object literal that you used in the constructor to define the binding:

```
// "TypeInteger" required from module "sap/ui/model/type/Integer"
oInput.bindProperty("value", {
    path: "/company/name",
    type: new TypeInteger()
});
```

> **i** Note
>
> Some controls offer convenience methods for their main properties that are most likely to be bound by an application:
>
> ```
> oTextField.bindValue("/company/name");
> ```

To **remove** a property binding, you can use the `unbindProperty` method. The property binding is removed automatically whenever a control is destroyed:

```
oTextField.unbindProperty("value");
```

Formatting Property Values

Values in data are often represented in an internal format and need to be converted to an external format for visual representation, especially numbers, dates, and times with locale-dependent external formats. SAPUI5 provides two different options for converting data. You can use both options for each binding, you don't have to use one option consistently throughout your app:

- Formatter functions for one-way conversion
- Data types in two-way binding
  Data types can be used to parse user input in addition to formatting values.

Using a Formatter Function

If you define the property binding in the **XML view**, you need to define a formatter function (`roundToMillion`) in the view controller:

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel"
], function (Controller, JSONModel) {
    "use strict";
    return Controller.extend("sap.ui.sample.App", {
        ..............
        roundToMillion: function(fValue) {
            if (fValue) {
                return "> " + Math.floor(fValue/1000000) + "M";
            }
            return "0";
        }
```

```
    });
});
```

The `this` context of a formatter function is generally set to the control (or managed object) that owns the binding. However, in XML views, the reference to the formatter is done in the view controller by putting a dot (`.`) in front of the name of the formatter function (`{ formatter: '.myformatter' }`). In this case, the formatter's `this` context is bound to the controller.

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Input
        value="{ path:'/company/revenue',
        formatter: '.roundToMillion'}"
    />
</mvc:View>
```

If you use **JavaScript**, you can pass the formatter function as a third parameter to the `bindProperty` method, or you can add the binding info with the `formatter` key. The `formatter` has a single parameter `value`, which is the value that is to be formatted, and is executed as a member of the control, meaning it can access additional control properties or model data.

```
//"Input" required from module sap/m/Input
oTextField.bindProperty("value", "/company/title", function(sValue) {
    return sValue && sValue.toUpperCase();
});
oControl = new Input({
    value: {
        path:"/company/revenue",
        formatter: function(fValue) {
            if (fValue) {
                return "> " + Math.floor(fValue/1000000) + "M";
            }
            return "0";
        }
    }
})
```

Because it can contain any JavaScript, the formatter function can be used for formatting a value and also for performing type conversions or calculating results, for example, to show a special traffic light image depending on a Boolean value:

```
oImage.bindProperty("src", "/company/trusted", function(bValue) {
    return bValue ? "green.png" : "red.png";
});
```

⚠ Caution

The framework only updates a binding when one of the properties included in the binding changes. If the formatter uses another property value that is not part of the binding definition, the framework won't know that the result depends on that additional property and could miss necessary updates. Therefore, make sure that you declare a composite binding referencing all necessary properties (maybe even from different models).

Using Data Types

The data type system enables you to format and parse data, as well as to validate whether the entered data lies within any defined constraints. SAPUI5 comes with several predefined and ready-to-use types, referred to as simple types. For more information, see Formatting, Parsing, and Validating Data [page 854].

Here's how you can use these types in an XML view:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Input
        value="{ path:'/company/revenue',
        type: 'sap.ui.model.type.Integer'}"/>
</mvc:View>
```

You can also provide parameter values for some of the simple types in your XML view. These are declared as `formatOptions`, as you can see in the Float type sample below. Permitted `formatOptions` are properties of the corresponding data type. For more information, see the *API Reference* in the Demo Kit.

```
<mvc:View
   controllerName="sap.ui.sample.App"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">
   <Input
      value="{ path:'/company/revenue',
           type: 'sap.ui.model.type.Float',
           formatOptions: {
                   minFractionDigits: 2,
                   maxFractionDigits: 2
           }
      }"/>
</mvc:View>
```

Using JavaScript, you can define a type to be used for a property binding by passing it as a third parameter in `bindProperty` or by adding it to the binding information by using the key `type`, as shown here:

```
// "TypeString" required from module "sap/ui/model/type/String"
// "Input" required from module "sap/m/Input"
// "TypeFloat" required from module "sap/ui/model/type/Float"
oTextField.bindProperty("value", "/company/name", new
sap.ui.model.type.String());
oControl = new sap.m.Input({
    value: {
        path:"/company/revenue",
        type: new TypeFloat({
            minFractionDigits: 2,
            maxFractionDigits: 2
        })
    }
})
```

Predefined data types also offer visual feedback for erroneous user input. To turn this feature on, add the following line to your controller's `init` function:

```
sap.ui.getCore().getMessageManager().registerObject(this.getView(), true);
```

You can define **custom types** by inheriting from `sap.ui.model.SimpleType` and implementing the three methods `formatValue`, `parseValue`, and `validateValue`. `formatValue` is called whenever the value in the model is changed to convert it to the type of the control property it is bound to, and may throw a

`FormatException`. `parseValue` is called whenever the user has modified a value in the UI and the change is transported back into the model. It may throw a `ParseException` if the value cannot be converted. If parsing is successful, `validateValue` is called to check additional constraints, such as minimum or maximum value, and throws a `ValidateException` if any constraints are violated.

```
// "SimpleType" required from module "sap/ui/model/SimpleType"
// "ValidateException" required from module "sap/ui/model/ValidateException"
var Zipcode = SimpleType.extend("sap.ui.sample.Zipcode", {
    formatValue: function(oValue) {
        return oValue;
    },
    parseValue: function(oValue) {
        return oValue;
    },
    validateValue: function(oValue) {
       if (!/^(\d{5})?$/.test(oValue)) {
            throw new ValidateException("Zip code must have 5 digits!");
       }
    }
});
```

You can use your custom types in XML views or JavaScript in the same way as you would apply predefined types:

```
<mvc:View
   controllerName="sap.ui.sample.App"
   xmlns="sap.m"
   xmlns:mvc="sap.ui.core.mvc">

   <Input
      value="{ path:'/company/zip',
      type: 'sap.ui.sample.Zipcode'
     }"/>
</mvc:View>
```

Changing the Binding Mode

By default, all bindings of a model instance have the default binding mode of the model, but you can change this behavior if needed. When creating a `PropertyBinding`, you can specify a different binding mode, which is then used exclusively for this specific binding. Of course, a binding can only have a binding mode that is supported by the model in question.

```
// "JSONModel" required from module "sap/ui/model/json/JSONModel"
// "Input" required from module "sap/m/Input"
// "BindingMode" required from module "sap/ui/model/BindingMode"
    var oModel = new JSONModel();
    // default binding mode is two way
    oModel.setData(myData);
    sap.ui.getCore().setModel(oModel);
    var oInputFirstName = new Input ();

    // bind value property one way only
    // propertyname, formatter function, binding mode
    oInputFirstName.bindValue("/firstName", null, BindingMode.OneWay);
    oInputFirstName.placeAt("target1");
    oInputLastName = new Input();
    // bind value property two way (default)
    oInputLastName.bindValue("/lastName");
```

```
    oInputLastName.placeAt("target2");
```

In the example above, two `Input` fields are created and their `value` property is bound to the same property in the model. The first `Input` binding has a one-way binding mode, whereas the second `Input` has the default binding mode of the model instance, which is two-way. For this reason, when text is entered in the first `Input`, the value will **not** be changed in the model. This only happens if text is entered in the second `Input`. Then, of course, the value of the first `Input` will be updated as it has a one-way binding, that is, from model to view.

API Reference: `sap.ui.base.ManagedObject.bindProperty`
Binding Syntax [page 840]
Formatting, Parsing, and Validating Data [page 854]

Context Binding (Element Binding)

Context binding (or element binding) allows you to bind elements to a specific object in the model data, which will create a binding context and allow relative binding within the control and all of its children. This is especially helpful in master-detail scenarios.

Let's assume we have the following JSON data:

```
{
    "company" : {
        "name"  : "Acme Inc."
        "street": "23 Franklin St."
        "city"  : "Claremont"
        "state" : "New Hampshire"
        "zip"    : "03301"
        "revenue": "1833990"
    }
}
```

Here's how you would use element binding in an XML view:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Input id="companyInput"
        binding="{/company}"
        value="{name}"
        tooltip="The name of the company is '{name}'"/>
</mvc:View>
```

By setting `binding="{/company}"`, we can refer to `company` children without having to qualify the full binding path, when binding `Input` control's properties such as the `value`. Using plain property binding, our XML view would look like this:

```
<mvc:View
```

```
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Input id="companyInput"
        value="{/company/name}"
        tooltip="The name of the company is '{/company/name}'}"/>
</mvc:View>
```

To define an element binding in JavaScript, for example in a controller, use the `bindElement` method on a control:

```
var oInput = this.byId("companyInput")
oInput.bindElement("/company");
oInput.bindProperty("value", "name");
```

Element binding is especially interesting for containers or layouts containing many controls that are all visualizing properties of the same model object. Here's an XML view with a `VerticalLayout` using element binding:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <l:VerticalLayout id="vLayout"
        binding="{/company}"
        width="100%">
            <Text text="{name}" />
            <Text text="{city}" />
            <Text text="{county}" />
    </l:VerticalLayout>
</mvc:View>
```

To realize this in JavaScript, proceed as follows in your controller:

```
var oVerticalLayout = this.getView().byId('vLayout');
oVerticalLayout.bindElement("/company");
oVerticalLayout.addContent(new Text({text: "{name}"}));
oVerticalLayout.addContent(new Text({text: "{city}"}));
oVerticalLayout.addContent(new Text({text: "{county}"})););
```

Given your XML view contains a `VerticalLayout`, it will look like this:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <l:VerticalLayout id="vLayout"
        width="100%"/>
</mvc:View>
```

Setting a New Context for the Binding (Master-Detail)

You create a new binding context for an element that is used to resolve bound properties or aggregations relative to the given path. You can use this method if the existing binding path changes or has not been provided before, for example in master-detail scenarios, as outlined below.

Let's look at the following JSON model featuring a company list:

```
{
    companies : [
        {
            name : "Acme Inc.",
            city: "Belmont",
            state: "NH",
            county: "Belknap",
            revenue : 123214125.34
        },{
            name : "Beam Hdg.",
            city: "Hancock",
            state: "NH",
            county: "Belknap"
            revenue : 3235235235.23
        },{
            name : "Carot Ltd.",
            city: "Cheshire",
            state: "NH",
            county: "Sullivan",
            revenue : "Not Disclosed"
        }]
}
```

Let's take this simple view, containing a single input control:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <Input id="companyInput"
         value="{name}"/>
</mvc:View>
```

In your controller, you can now bind the input control as follows:

```
var oInput = this.byId("companyInput");
oInput.bindElement("/companies/0");
```

The XML view has bound the `value` of the input to the `name` property in the model. As the path to this property in the model is not set, this will not resolve. To resolve the binding, you use the `bindElement` method which creates a new context from the specified relative path.

To remove the current binding context, call the `unbindElement` method on the input control. By doing this, all bindings now resolve relative to the parent context again.

You can also use the `bindElement` method in conjunction with list binding. Let's consider the following extension of our JSON data:

```
{
    regions: [
        {
            name: "Americas",
            companies : [
            {
                name : "Acme Inc.",
                zip : "03301",
                city: "Belmont",
                county: "Belknap",
                state: "NH",
                revenue : 123214125.34,
                publ: true
```

```
            },
            {
                name : "Beam Hdg.",
                zip : "03451",
                city: "Hancock",
                county: "Sullivan",
                state: "NH",
                revenue : 3235235235.23,
                publ: true
            },
            {
                name : "Carot Ltd.",
                zip : "03251",
                city: "Cheshire",
                county: "Sullivan",
                state: "NH",
                revenue : "Not Disclosed",
                publ: false
            }]
        },{
            name: "DACH",
            companies : [
            {
                name : "Taubtrueb",
                zip : "89234",
                city: "Ginst",
                county: "Musenhain",
                state: "NRW",
                revenue : 2525,
                publ: true
            },
            {
                name : "Krawehl",
                zip : "45362",
                city: "Schlonz",
                county: "Humpf",
                state: "BW",
                revenue : 2342525,
                publ: true
            }]
        }
    ]
}
```

Say we want to display companies in a `sap.m.List` control. Here's what the XML view will look like:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
      <List id=”companyList” items="{companies}">
        <items>
            <StandardListItem
         title="{name}"
         description="{city}"
            />
        </items>
      </List>
</mvc:View>
```

Please note that `items="{companies}"` cannot be resolved initially, since it is a relative path. In your controller, you can now provide an element binding for the list control:

```
var oList = this.byId("companyList");
oList.bindElement("/regions/0");
```

This will display the companies for region **Americas**, while the code below displays all companies in the **DACH** region (Germany, Austria, Switzerland):

```
var oList = this.byId("companyList");
oList.bindElement("/regions/1");
```

Formatting, Parsing, and Validating Data [page 854]

List Binding (Aggregation Binding)

List binding (or aggregation binding) is used to automatically create child controls according to model data.

Let's say we would like to display the following JSON model data in a `sap.m.List`:

```
{
    companies : [
        {
            name : "Acme Inc.",
            city: "Belmont",
            state: "NH",
            county: "Belknap",
            revenue : "123214125.34"
        },{
            name : "Beam Hdg.",
            city: "Hancock",
            state: "NH",
            county: "Belknap"
            revenue : "3235235235.23"
        },{
            name : "Carot Ltd.",
            city: "Cheshire",
            state: "NH",
            county: "Sullivan",
```

```
            revenue : "Not Disclosed"
        }]
}
```

Declarative List Binding in XML Views

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:mvc="sap.ui.core.mvc">
    <List id=”companyList” items="{path: '/companies', templateShareable:false}">
        <items>
            <StandardListItem
                title="{name}"
                description="{city}"
            />
        </items>
    </List>
</mvc:View>
```

The `List` element has both an `items` attribute and a nested `items` element:

- The attribute `items="{path: '/companies', templateShareable:false}"` binds the children of our json model's `companies` array to the list. This by itself is not enough to display the companies, instead it sets the parent path for the binding of all contained list items and their descendants. In addition you need to declare a nested element.
- The nested `items` element in our case contains a `StandardListItem`. This serves as a template for creating the individual list rows.

> **i Note**
>
> The binding paths of `StandardListItem` for properties `title` and `description` are relative to `companies`. This means that instead of having to write the whole binding path `title={/companies/name}`, you can simply write `title={name}`. By omitting the slash ‘/’ at the beginning, `{name}` is marked as a relative binding path.

Instead of using a `StandardListItem` as a list row template, you can also use any other `sap.m.` list item, such as:

- ActionListItem
- DisplayListItem
- CustomListItem
- ObjectListItem

For more examples and details on when to use which list item control, see the various list items in the Samples in the Demo Kit.

> **i Note**
>
> The model has a default size limit to avoid too much data being rendered on the UI. This size limit determines the number of entries used for the list bindings. The default size limit is 100 entries.
>
> This means that controls that don't support paging or don't request data in chunks (e.g. `sap.m.ComboBox`) only show 100 entries even though the model contains more items.

To change this behavior, you can set a size limit in the model by using `oModel.setSizeLimit`.

List Binding in the JavaScript Code

You can define list binding directly in JavaScript either in the `settings` object in the constructor or by calling the `bindAggregation` method. List binding requires the definition of a template, which is cloned for each bound entry of the list. For each clone that is created, the binding context is set to the respective list entry, so that all bindings of the template are resolved relative to the entry. The aggregated elements are destroyed and recreated whenever the bound list in the data model is changed.

To bind a list, you create a template or provide a factory function, which is then passed when defining the list binding itself. In the `settings` object, this looks as follows:

```
var oItemTemplate = new sap.ui.core.ListItem({text:"{name}"});
oComboBox = new sap.m.ComboBox({
    items: {
        path: "/companies",      //no curly brackets here!
        template: oItemTemplate
        templateShareable: false
    }
});
```

A template is not necessarily a single control as shown in the example above, but can also be a tree of controls. For each list entry, a deep clone of the template is created and added to the bound list.

You can also define the list binding by using the `bindAggregation` method of a control:

```
var oItemTemplate = new sap.ui.core.ListItem({text:"{name}"});
oComboBox.bindAggregation("items", {
path: "/companies",
template: oItemTemplate,
templateShareable: false
});
```

In addition, some controls have a typed binding method for lists that are likely to be bound by the application:

```
var oComboBox.bindItems("/companies", oItemTemplate);
```

To remove a list binding, you can use the `unbindAggregation` method:

```
oComboBox.unbindAggregation("items");
```

Controls with typed binding methods also provide a typed unbind:

```
oComboBox.unbindItems();
```

When a list is unbound, its aggregated controls are removed and destroyed by default. If you would like to keep the items in your `ComboBox`, for example, you can do so by using:

```
oComboBox.unbindAggregation("items", true);
```

Tutorial Step 12: Aggregation Binding Using Templates [page 244]
Binding Syntax [page 840]
Formatting, Parsing, and Validating Data [page 854]

Using Factory Functions

The factory function is a more powerful approach for creating controls from model data. The factory function is called for each entry of a control's aggregation, and the developer can decide whether each entry shall be represented by the same control with different properties or even by a completely different control for each entry.

The factory function comes with the parameters `sId`, which should be used as an ID for the new control, and `oContext`, which is for accessing the model data of the entry. The returned object must be of type `sap.ui.core.Element`. Here's how this scenario can be realized in an XML view and a controller using our JSON model data:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:l="sap.ui.layout"
    xmlns:mvc="sap.ui.core.mvc">
    <l:VerticalLayout
        content="{ path: '/companies', factory: '.createContent'}"
        class="sapUiContentPadding"
        width="100%"/>
</mvc:View>
```

Please note the `'.'` in `factory: '.createContent'`. The class `App.controller.js` contains the implementation of our factory method:

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/ui/model/type/String",
    "sap/ui/model/type/Float",
    "sap/m/Input",
    "sap/m/Text",
    "sap/m/CheckBox"
], function (Controller, JSONModel, StringType, Float, Input, Text, CheckBox ) {
    "use strict";
    return Controller.extend("sap.ui.sample.App", {
        onInit : function () {
        …
        },
        createContent: function (sId, oContext) {
        var oRevenue = oContext.getProperty("revenue");
            switch(typeof oRevenue) {
                case "string":
                    return new Text(sId, {
                        text: {
                            path: "revenue",
                            type: new StringType()
                        }
                    });
```

```
                case "number":
                    return new Input(sId, {
                        value: {
                            path: "revenue",
                            type: new Float()
                        }
                    });

                case "boolean":
                    return new CheckBox(sId, {
                        checked: {
                            path: "revenue"
                        }
                    });
            }
        },
    });
});
```

If you would like to avoid using the XML view, you would proceed as follows:

```
oVerticalLayout.bindAggregation("content", "/companies", function (sId,
oContext) {
    var oRevenue = oContext.getProperty("revenue");
    switch(typeof oRevenue) {
            case "string":
                return new sap.m.Text(sId, {
                    text: {
                        path: "revenue",
                        type: new sap.ui.model.type.String()
                    }
                });

            case "number":
                return new sap.m.Input(sId, {
                    value: {
                        path: "revenue",
                        type: new sap.ui.model.type.Float()
                    }
                });

            case "boolean":
                return new sap.m.CheckBox(sId, {
                    checked: {
                        path: "revenue"
                    }
                });
            }
        }
});
```

Tutorial Step 15: Aggregation Binding Using a Factory Function [page 257]

Sorting, Grouping, and Filtering for List Binding

Initial Sorting, Grouping and Filtering for List Binding

To provide initial **sorting and grouping** in an XML view, proceed as follows:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:l="sap.ui.layout"
    xmlns:mvc="sap.ui.core.mvc">
    <List items="{ path: '/companies',
        sorter: { path: 'county', descending: false, group: '.getCounty'},
        groupHeaderFactory: '.getGroupHeader'}">
        <items>
            <StandardListItem
                title="{name}"
                description="{city}"
            />
        </items>
    </List>

</mvc:View>
```

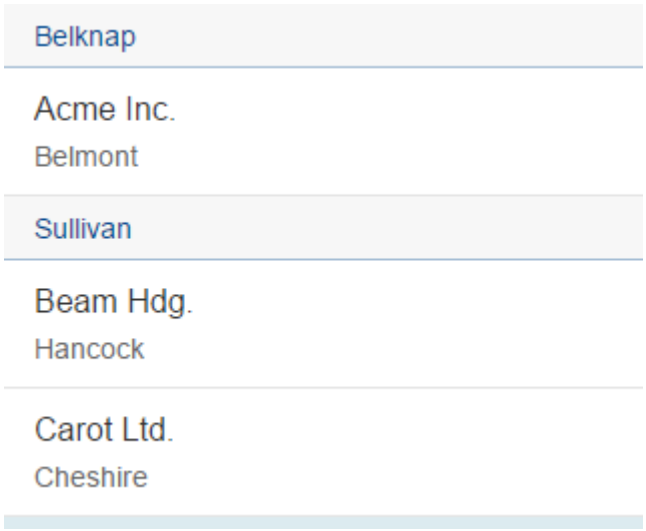
The `this` context of a group header factory function is generally set to the control (or managed object) that owns the binding. However, in XML views, the reference to the group header factory is done in the view controller by putting a dot (`.`) in front of the name of the group header factory function (`{ groupHeaderFactory:'.myGroupHeader' }`). In this case, the group header factory's this context is bound to the controller.

The list uses a sorter which sorts the list of companies in ascending order by the `county` column. It also groups its rows using the App.controller's `getCounty` method to provide the captions and the `getGroupHeader` function to provide non-standard group header controls, as shown here:

```
sap.ui.define([
    "sap/ui/core/mvc/Controller",
    "sap/ui/model/json/JSONModel",
    "sap/m/GroupHeaderListItem "
], function (Controller, JSONModel, GroupHeaderListItem) {
    "use strict";
    return Controller.extend("sap.ui.sample.App", {
        onInit : function () {
            …
        },
        getCounty: function(oContext) {
            return oContext.getProperty('county');
        },

        getGroupHeader: function(oGroup) {
            return new GroupHeaderListItem({
                title : oGroup.key
            }
        );
    },
});
```

As you can see, `getCounty` generates the group caption, which in this case is the county of the current companies. `getGroupHeader` serves as a group header factory function. After sorting and grouping, the company list looks like this:



The following XML snippet provides initial filtering:

```
<mvc:View
    controllerName="sap.ui.sample.App"
    xmlns="sap.m"
    xmlns:l="sap.ui.layout"
    xmlns:mvc="sap.ui.core.mvc">
    <List items="{ path: '/companies',
        filters: [{path: 'city', operator: 'StartsWith', value1: 'B'},
            {path: 'revenue', operator: 'LT', value1: 150000000}]}">
        <items>
            <StandardListItem
                title="{name}"
                description="{city}"
            />
        </items>
    </List>
</mvc:View>
```

The example shown here will only display companies whose city name begins with a ‘b’ and whose revenue is less than 150 million. As you can see, you can provide more than one filter, each of which may refer to different columns using different filter operators. For a complete list of permitted filter operators, see sap.ui.model.FilterOperator in the *API Reference* part of the Demo Kit.

As shown below, initial sorting, grouping and filtering can of course also be provided using JavaScript.

You can define a sorter and/or filters:

```
sap.ui.define([
    "sap/ui/model/Sorter",
    "sap/ui/model/Filter"
], function(Sorter, Filter) {
//returns group header captions
var fnGetCounty = function(oContext) {
    return oContext.getProperty('county');
}
var oSorter = new Sorter({
    path: 'county',
    descending: false,
```

```
    group: fnGetCounty});
var oFilterCity = new Filter("city",
    sap.ui.model.FilterOperator.StartsWith, "B"),
    oFilterRevenue = new sap.ui.model.Filter("revenue",
        sap.ui.model.FilterOperator.LT, 150000000);
);
});
```

You can pass sorters and filters to the list binding:

```
var oList = new sap.m.List({
    items: {path: "/companies", template: oItemTemplate,
        sorter: oSorter, filters:[oFilterCity, oFilterRevenue]
    }
});
```

You can also use the other list binding possibilities (for example `bindAggregation` or `bindItems`) and provide the sorter and filters as parameters.

Manual Sorting and Filtering for List Binding

You can sort or filter data manually after the list binding is complete by getting the corresponding binding and calling the sort/filter function:

```
// manual sorting
oList.getBinding("items").sort(oSorter);
// manual filtering
oList.getBinding("items").filter([oFilterCity, oFilterRevenue]);
```

> **i Note**
>
> `getBinding` requires the name of the bound list. In this example, we are looking at the `items` of the `sap.m.List` control.

For more information about the various sorting and filter methods and operators, see the documentation for Filter, Sorter, and Filter operations under sap.ui.model in the *API Reference* part of the Demo Kit.

Using Complex Syntax to Add Filters and Sorters

Complex syntax can be used to add filters and sorters for list binding. One or multiple objects can be defined.

```
<table:Table rows="{
    path: '/table',
    filters: [{
        path: 'field3',
        operator: 'EQ',
        value1: 'test'
    }],
    sorter: [{
        path: 'field1',
        descending: false
    }, {
        path: 'field2',
```

```
        descending: true
    }]
 }">
...
</table:Table>
```

Lifecycle of Binding Templates

The lifecycle of the binding templates differs from the lifecycle of controls that are contained in an aggregation. Whenever a control object is destroyed, any aggregating object is destroyed as well. For list binding templates, you specify the behavior by using the additional property `templateShareable` in the parameter of the `bindAggregation` method of class `sap.ui.base.ManagedObject`.

In **XML views**, you can also use the `templateShareable` property by adding it to the binding info as follows:

```
<Table id="EmployeeEquipments" headerText="Employee Equipments" items="{
    path: 'EMPLOYEE_2_EQUIPMENTS',
    templateShareable: false
}">
    <columns>
        <!-- ... -->
    </columns>
    <items>
        <ColumnListItem>
            <cells>
                <Text text="{ID}"/>
            </cells>
            <cells>
                <Text text="{EQUIPMENT_2_PRODUCT/Name}"/>
            </cells>
            <cells>
                <Text text="{Category}"/>
            </cells>
            <cells>
                <!-- Name="PRODUCT_2_CATEGORY" Type="Collection(...)" -->
                <List items="{
                    path: 'EQUIPMENT_2_PRODUCT/PRODUCT_2_CATEGORY',
                    templateShareable: true
                }">
                    <StandardListItem title="{CategoryName}"/>
                </List>
            </cells>
            <cells>
                <Text text="{EQUIPMENT_2_PRODUCT/PRODUCT_2_SUPPLIER/
Supplier_Name}"/>
            </cells>
        </ColumnListItem>
    </items>
</Table>
```

- `templateShareable = "false"` (preferred setting)
  If you set the parameter to `false` the lifecycle is controlled by the framework. It will destroy the template when the binding is removed (`unbindAggregation`, `unbindItems`)
- `templateShareable = "true"`
  If you set the parameter to `true` the template is **not** destroyed when (the binding of) the aggregated object is destroyed. Use this option in the following cases only:
  - The template is reused in your app to define an additional list binding.

Since the template is not destroyed, this could also affect some other aggregation that uses the same template at a later point in time.

- The parent control that contains the list binding with the template is cloned. The binding info is used in the clone as well.
  This means, when `templateShareable` is set to `true`, the template will not be cloned, when it is set to `false` it will be cloned when the parent is cloned.

In these cases, the app has to make sure that the templates are properly cleaned up at some point in time - at the latest when the corresponding controller or component is destroyed.

- If the parameter is undefined, (neither `true` nor `false`), the framework checks at several points in time whether all list bindings are removed. If there are no bindings, the templates is marked as `candidate for destroy()`, but it is not immediately destroyed. The candidate is destroyed in the following cases:
  - A **new object with the same ID** is created.
  - The component that owns the objects is destroyed.

  If the framework determines that a "candidate for destroy" is still in use in another binding or in a clone operation, the framework makes sure that the candidate is not destroyed by implicitly setting `templateShareable` to `true` (as this best reflects how the app deals with the template). But now the template is not destroyed at all (an error message is issued), and the app implementation needs to make sure that the binding template is destroyed as soon as it is no longer needed.

> **i Note**
>
> The error messages are:
> - *A binding template that is marked as 'candidate for destroy' is reused in a binding.*
> - *During a clone operation, a template was found that neither was marked with 'templateShareable:true' nor 'templateShareable:false'.*

> **⚠ Caution**
>
> To leave the parameter undefined is **very error-prone**, therefore we don't recommend this! Always set the parameter explicitly to `true` or `false`.

Extended Change Detection

Extended change detection offers fine-grained information on the actual data changes. This can be used, for example, to only update the DOM when really necessary and avoid complete rerendering of a huge list whenever data is changed.

The binding base class already offers a `Change` event, which is fired whenever the bound data has been changed. This is sufficient for bindings like property and context binding. Since lists can contain a huge amount of data, you need more detailed information on the changes to avoid a complete rerendering of the whole list each time data has been changed on the UI.

Calculation of Differences

When extended change detection is enabled, an algorithm is executed to compare the last returned context array with the current context array and the differences is attached to the array of contexts as an additional property named `diff` whenever the `getContexts` method is called. The following results are possible:

- There is no `diff` property on the context array
  The data was completely changed or a difference could not be calculated. In this case there is no possibility for fine-grained update, a complete recreation or rerendering is necessary.
- The `diff` property returns an empty array
  The algorithm has been executed, but could not find any differences between the initial and the current state. This may occur if data within the list has been changed, but detection of updates have not been enabled for the extended change detection.
- The `diff` property returns an array of different entries
  The difference has been calculated and can be used by the control or application to update dependent structures in a fine grained manner

The difference between the state when the list was initially loaded and the current state is provided to the control as an array that contains `insert` and `remove` entries that contain the actual changes.

Example

Old State	New State
`["one", "two", "three", "four", "five"]`	`["one", "three", "four", "five", "six"]`

Difference
`[{index: 1, type: "delete"}, {index: 4, type: "insert}]`

The algorithm is implemented in the utility method `jQuery.sap.arraySymbolDiff`, which tries to calculate the smallest possible difference for the transition from old to the new state. The indexes are calculated in a way that they are valid after all previous steps have been applied, so it can be used in a loop to update an existing array, without any additional index shift needed.

Caution

- Extended change detection calculates the difference between the context arrays returned by calling `getContexts`. This means, it is completely independent from the `startIndex` and `length` parameters. Any additional call to `getContexts`, either by the app or the control itself, may trigger a difference calculation and may cause update problems. If you want to access the current context of a list binding, you should use `getCurrentContexts` in your app instead.
- When a `ListBinding` is firing a `Refresh` event, the call to `getContexts` caused by this event is used to inform the `ListBinding` on the `startIndex` and `length` of entries requested by the control. No difference calculation is done on this specific call, as controls do not use the result of this call but instead wait for the data returned by the server.

Using Extended Change Detection in App Development

If a control you want to use in your app to visualize list entries supports extended change detection, you should make sure that each entity of your model has a unique key to improve performance.

- For OData models, the unique keys are automatically provided.
- For all other models (like a JSON model), you have to define the keys either by using a key property or by using a function that calculates the key in the binding info of their list binding as in the following example:

`key` **property**

```
oControl.bindItems({
  path: "/listData",
  key: "id"
});
```

`key` **function**

```
oControl.bindItems({
  path: "/listData",
  key: function(oContext) {
    return
oContext.getProperty("user") +
oContext.getProperty("timestamp");
  }
});
```

Using Extended Change Detection in Control Development

Extended change detection is disabled by default. If your control is meant to have only a few children like a toolbar with buttons, you should not activate extended change detection because a copy of the previous state would then always be kept unnecessarily in the binding.

With extended change detection the control uses specific `insert` and `remove` calls only for elements that need to be added or removed instead of recreating all elements of an aggregation or setting new binding contexts on all aggregated elements.

You activate extended change detection for your control by setting the `bUseExtendedChangeDetection` property either on the control prototype or a specific control instance. The `ManagedObject` class takes care of reading and applying the information about the differences to aggregations with the `enableExtendedChangeDetection` method. The method has the following parameters:

- `bDetectUpdates`
  Defines whether data changes within the same entity should also be contained in the `diff`. This is especially relevant when a factory function is used to create child controls, so depending on the data a different control may be created by the same entity.
- `vKey`
  Defines how a unique symbol for each row is calculated, which is then used for the calculation of differences. This can either be a property name (in case the data already has something like a `key` property) or a function that is able to calculate such a unique key from the entity data.

You also have to implement the specific aggregation modifier methods to avoid the rerendering of the complete UI and only to a fine-grained DOM update.

> **i Note**
>
> If your control has a custom `updateAggregation` method (that means control takes care for updating the aggregation) you have to make sure in your implementation that the difference information is interpreted and applied.

For more information, see the API Reference: `sap.ui.base.ManagedObject.bindAggregation`.

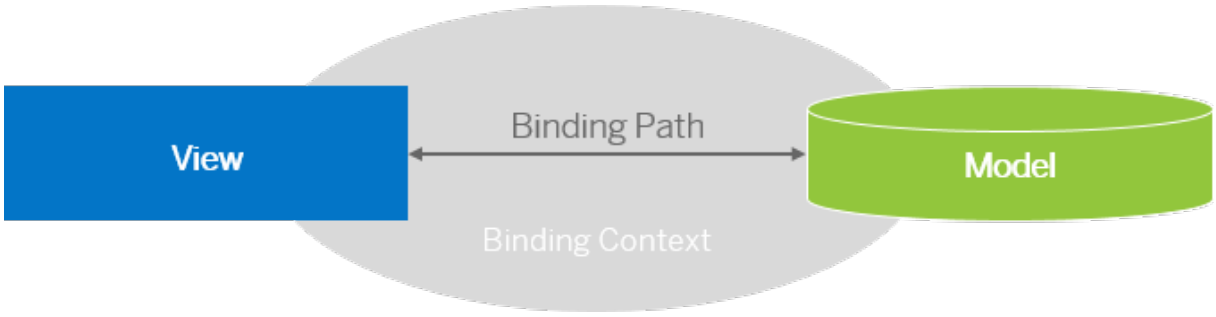
Binding Syntax

You bind UI elements to data of a data source by defining a binding path to the model that represents the data source in the app.

When defining a binding path for a control, a binding context is created which connects this control to a data model. The UI control then gets the data through that context and displays it on the screen.



- Views [page 787]
- Binding Path [page 842]
- Models [page 882]

Simple Binding

To reference model data in a view , you can use the simple binding syntax "`{`*/path/to/data*`}`":

```
<Input value="{/firstName}"/>
```

You can add other properties like formatters or data types:

- Data type:

```
<Input value="{path: '/firstName', type: 'sap.ui.model.type.String'}"/>
```

- Formatter:

```
<Input value="{path: '/firstName', formatter:'my.globalFormatter'}"/>
```

For more information, see Binding Path [page 842].

For more information about data types and formatters, see Formatting, Parsing, and Validating Data [page 854].

Composite Binding

If a control requires data from multiple different model properties, you use a `parts` array of `path`s to define composite binding paths:

```
<TextField value="{
    parts: [
        {path:'birthday/day'},
        {path:'birthday/month'},
        {path:'birthday/year'}
    ],
    formatter:'my.globalFormatter'
}"/>
```

For more information, see Composite Binding [page 843] and Examples for Data Binding in Different View Types [page 851].

Expression Binding in XML Views

Expression binding is a simple way to calculate values directly in the view. For example, if you want to change the color of the price depending on whether it is above or below some threshold. With expression binding you don't have to declare a separate formatter:

```
<ObjectStatus state=="{= ${products>UnitPrice}  > ${/priceThreshold} ? 'Error' :
'Success' }"/>
```

For more information, see Expression Binding [page 845].

Property Metadata Binding for OData Services

With metadata binding, you can bind properties of a control to the corresponding property that is defined in the metadata of an OData service:

```
<Input maxLength="{/#Company/ZipCode/@maxLength}"/>
```

For more information, see Property Metadata Binding [page 851].

Binding Path

Binding paths address the different properties and lists in a model and define how a node in the hierarchical data tree can be found.

A binding path consists of a number of name tokens, which are separated by a separator char. In all models provided by the framework, the separator char is the slash "/".

A binding path can either be absolute or relative: Absolute binding paths start with a slash, relative binding paths start with a name token and are resolved relative to the context of the control that is bound. A context exists either for each entry of the aggregation in case of aggregation binding or can be set explicitly for a control by using the `setBindingContext` method.

When you use multiple models, specify the model name within the binding path to address the correct model. The same applies for setting a binding context for such a model. The binding path must start with the model name followed by a '>' as shown in the following example for setting a binding context.

```
oControl.setBindingContext(oContext );
oControl.setBindingContext(oContext,"myModelName");
```

Binding path examples:

```
'/Products/0/ProductName'
'/Products(0)/ProductName'
'ProductName'
//with model name
'myModelName>/Products/0/ProductName'
'myModelName>/Products(0)/ProductName'
'myModelName>ProductName'
```

Composite Binding

Calculated fields enable the binding of multiple properties in different models to a single property of a control.

The value property of a text field, for example, may be bound to a property `firstName` and a property `lastName` in a model. The application can access these values in a formatter function and can decide how they should be processed or combined together. If no formatter function is specified, the values are joined together by default. You can use the `useRawValues` property to specify if the parameter values in the formatter function are formatted according to the type of the property or not.

The multiple property bindings are stored in a `CompositeBinding` and can be accessed by calling the `getBindings` function. You can access the composite binding, for example, by using the `getBinding('value')` function of the control. The composite binding has no path, model, context, and type because it contains multiple property bindings containing the necessary information. A composite binding may, for example, store two property bindings which belong to different models and have different types.

If you have specified a formatter function, it is also available in the composite binding.

There are several options to create multiple bindings for a control. The syntax is very similar to the normal single binding declaration.

Each binding is created by the specified parts and assigned information. A part must contain the path to the property in the model and may contain additional information for the binding, for example a type.

Constructor Declaration

1. Use binding objects to add additional parameters, for example the type:

```
oTxt = new sap.m.Input({
    value: {
        parts: [
                {path: "/firstName", type: new sap.ui.model.type.String()},
                {path: "/lastName"},
                {path: "myModel2>/amount", type: new
sap.ui.model.type.Float()} // path to property in another model
               ]
         }
});
```

2. Use strings which only take the path:

```
oTxt = new sap.m.Input({
    value: {
        parts: [
                "/firstName",
                "/lastName",
                "myModel2>/fraud" // path to property in another model
               ]
         }
});
```

Bind Property Declaration

1. Use binding objects to add additional parameters, for example the type:

```
oTxt.bindValue({
    parts: [
             {path: "/firstName", type: new sap.ui.model.type.String()},
             {path: "/lastName"}
            ]
});
```

2. Use strings which only take the path:

```
oTxt.bindValue({
    parts: [
             "/firstName",
             "/lastName"
            ]
});
```

These samples also work with a relative binding path, when you use them as a template in a list binding.

Complex Syntax for Calculated Fields

Complex (or "extended") syntax can be used for calculated fields in declarative views, such as HTML and XML views.

To use the feature in your SAPUI5 application, set the configuration flag `bindingSyntax` in the bootstrap as follows:

```
<script id="sap-ui-bootstrap"
      ...
        data-sap-ui-bindingSyntax="complex">
    </script>
```

The following examples show how to use the feature:

- You can mix text with calculated fields as follows:

```
<Label text="Hello Mr. {
                         path:'/singleEntry/firstName',
                         formatter: '.myFormatter'
                        },
                        {
                         /singleEntry/lastName
                        }
 " />
```

> **i Note**
>
> Use translatable text in your application.

- Use a syntax with leading quotation marks ("...") if you use MVC and your formatter or type is located in the controller. In the following example, the existing type or formatter function in the controller is used:

```
<TextField value="{
```

```
                    path:'gender',
                    formatter:'.myGenderFormatter'
                   }
                   {firstName},
                   {lastName}
"/>
```

- If you have a global formatter function, use the following syntax:

```
<TextField value="{
              parts: [
                      {path:'birthday/day'},
                      {path:'birthday/month'},
                      {path:'birthday/year'}
                     ],
              formatter:'my.globalFormatter'
}"/>
```

- For a global type that is created with the specified format options, see the following example:

```
<Label text="A type test: {
                           path:'/singleEntry/amount',
                           type:'sap.ui.model.type.Float',
                           formatOptions: { minFractionDigits: 1}
                          } EUR
"/>
```

Expression Binding

Expression binding is an enhancement of the SAPUI5 binding syntax, which allows for providing expressions instead of custom formatter functions.

Using expression binding saves the overhead of defining a function and is recommended if the formatter function has a trivial implementation like a comparison of values. Expression binding is especially useful in the context of SAPUI5 XML templating where XML views with templating are preprocessed and the SAPUI5 controller as the natural place to put custom formatter functions is not available.

To use expression binding, you need to enable complex binding syntax by using configuration setting `bindingSyntax` to `complex`.

> **i Note**
>
> Complex syntax is automatically activated when the `compatVersion` is set to `edge` or to version `1.28` or higher. For more information, see Configuration Options and URL Parameters [page 703].

An expression binding is specified in an XML view by one of the following two options:

- `{=`*expression*`}`
  This variant uses one-way binding. This allows the automatic recalculation if the model values change.
- `{:=`*expression*`}`
  This variant uses one-time binding, meaning that the value is calculated only once. This variant needs less resources because no change listeners to the model have to be maintained.

The syntax of the *expression* is similar to JavaScript syntax, but you can only use a subset of the JavaScript expression syntax as defined in the table below. Additionally, you can embed values from the model layer into an expression as additional bindings by using one of the following syntaxes:

- `${`*binding*`}`
- `%{`*binding*`}`

binding can either be a simple path, or a complex binding. The embedded binding `${`*binding*`}` delivers a value formatted according to the target type of the control property the expression binding applies to, for example, "boolean" in case of `<Icon src="sap-icon://message-warning" visible="{= ${status} === 'critical' }">`. This can be undesirable or even lead to errors, for example, if OData V4 automatically adds the correct type for the "status" property which is string-like, not boolean. In such cases, use the syntax `%{binding}` instead. It is just a shortcut for `${path : 'binding', targetType : 'any'}`. In rare cases, you might also want to specify a different "targetType", for example "string", "boolean", "int" or "float". For more information how these values relate to OData types, see the sap.ui.model.odata.type API documentation or explore the XML Templating: UI5 OData Types sample in the Demo Kit. For more information about `targetType`, see the sap.ui.base.ManagedObject#bindProperty API documentation in the Demo Kit.

i Note

Expression binding can also be used with JavaScript. For example:

```
new Text({"visible" : "{= ${status} === 'critical' && ${amount} > 10000 }"});
```

or

```
new Icon({color : "'{= encodeURIComponent(${/ID}) }'"});
```

i Note

An expression binding does **not** validate binding paths. As a result, an expression binding will **not** detect incorrect or misspelled binding paths. But if you use an OData V4 model and try to bind data that does **not** exist in the model, a warning is logged in the console.

To embed a path containing a closing curly brace into an expression binding, use a complex binding syntax: `${path:'...'}`, for example `"{:= ${path:'target>extensions/[${name} === \'semantics\']/value'} === 'email'}"`. You can use this also to avoid variable replacement by build tools like Maven for special names like "Description" or "Name".

Syntax Element	Symbol
Literal	number, for example `42`, `6.022e+23` or `-273.15`
	object, for example `{foo: 'bar'}`
	string, for example `'foo'`
	`null`
	`true`
	`false`

Syntax Element	Symbol
Grouping	(...), for example `3 * (4 + 10)`

Unary operator	`!`
	`+`
	`-`
	`typeof`

Multiplicative operator	`*`
	`/`
	`%`

Additive operator	`+` `-`

Relational operator	`<`
	`>`
	`<=`
	`>=`

Strict equality operator	`===` `!==`
Binary logical operator	`&&` `||`
Conditional operator	`?`
Member access operator with the `.` operator	**Note** With these, you can use members and member methods on standard types such as string, array, number, and so on. Example: `${message>/}.length >0` or `${/firstName}.indexOf('S').`

Syntax Element	Symbol
Function call	`<function name>(...)` Example: • `text="{= Math.max(${/value1}, ${/value2}, ${/value3}) }"` **Note** You can use functions that are available via global symbols, such as `Math.max(...)` or `isNaN(...)`.
Array literals	`[...]`, for example `[2,3,5,7,11]`
Property/array access	`o[...]`, for example `'foo/bar'.split('/')[1]`
`in` operator	`'PI' in Math` (true) or `0 in []` (false)
Global symbol	`Array`, `Boolean`, `Date`, `encodeURIComponent`, `Infinity`, `isFinite`, `isNaN`, `JSON`, `Math`, `NaN`, `Number`, `Object`, `parseFloat`, `parseInt`, `RegExp`, `String`, `undefined`

Simple Example

Note

With expression binding you only need the XML view but no controller logic.

The following example shows how you use the custom formatter function to map an XML view to an expression binding in the XML view without controller logic.

The icon is only displayed if the status property in the view's default model has the value `critical`. You can use expression binding to replace the formatter function `myFormatter` in the controller with an expression binding in the XML view. You no longer need to implement any formatter function.

The application version without expression binding consists of the XML view (`sample.App.view.xml`) and the controller:

XML view (`sample.App.view.xml`)

```
<mvc:View controllerName="sample.App" xmlns="sap.ui.core"
xmlns:mvc="sap.ui.core.mvc">
...
  <Icon src="sap-icon://message-warning" visible="{path:'status',
formatter:'.myFormatter'}">
...

</mvc:View>
```

Controller (`sample.App.controller.js`)

```
...
myFormatter: function(sStatus) {
  return sStatus === "critical";
}
...
```

When using expression binding, however, you only need the XML view without controller logic (`sample.App.view.xml`):

```
<mvc:View controllerName="sample.app" xmlns="sap.ui.core"
xmlns:mvc="sap.ui.core.mvc">
...
  <Icon src="sap-icon://message-warning" visible="{= ${status} === 'critical' }">
...
</mvc:View>
```

> **i Note**
>
> Some symbols need to be escaped in XML views, for example `&&` needs to be escaped with `&&`.

More Complex Expressions

With the expression syntax sketched above it is possible to create more complex expressions as shown in the examples below.

> **i Note**
>
> We recommend to use formatter functions instead of very complex and hard-to-read expressions. Some characters that are used by operators, however, need to be escaped in XML, for example the left angle bracket (<) and the ampersand (&). Escaping makes it more difficult to read the expression. To avoid escaping, use one of the following options:
>
> - Rephrase the expression to make it more readable, for example, use `a > b` instead of `b < a`.
> - Use a custom formatter function.
>
> For more information about escaping in XML, see the W3C XML specification at http://www.w3.org/TR/xml/#syntax .

Examples for more complex expressions:

```
<!-- Set to visible if the status is critical and the amount
is above the threshold (note escaping of &&). -->
visible="{= ${status} === 'critical' &amp;&amp; ${amount} > 10000 }"
```

```
<!-- Text for amount level using language-dependent texts
from the resource model. -->
text="{= ${/amount} > 10000 ? ${i18n>/high} : ${i18n>/normal} }"
```

```
<!-- Set to visible if the rating is VIP, ignoring case
or if the order amount is greater than 10,000. -->
visible="{= ${/rating}.toUpperCase() === 'VIP' || ${/orderAmount} > 10000 }"
```

```
<!-- Set to visible if the rating contains VIP, ignoring
 the case. -->
visible={= RegExp('vip', 'i').test(${/rating}) }
```

```
<!-- Text is maximum of three values. -->
text="{= Math.max(${/value1}, ${/value2}, ${/value3}) }"
```

```
<!-- Control is enabled only if the order status is set. -->
enabled="{= ${/orderStatus} !== null }"
```

```
<!-- Set text to the second string 'middle', access second
element in the array generated via 'split'. -->
text="{= 'small@middle@long'.split('@')[1] }"
```

```
<!-- Concatenate literal strings and expression bindings
or bindings. -->
text="Hello {=${gender}==='male' ? 'Mr.' : 'Mrs.'} {lastName}"
```

```
<!-- Control such as a button in the toolbar of a table is
enabled only if there are items in the table. -->
enabled="{= ${/items}.length>0 }"
```

```
<!-- Set text by using a composite binding that combines
several values in a formatter defined by a parameterized
entry of an i18n language resource. -->
<!-- i18n language resource -->
successMsg=Message is available from {0} until {1}
errorMsg=Message is too short
<!-- View -->
<mvc:View controllerName="sample.App" xmlns="sap.m" xmlns:mvc="sap.ui.core.mvc">
...
   <Text text="{= ${/data/message}.length &lt; 20
      ? ${i18n>errorMsg}
      : ${parts: [
         {path: 'i18n>successMsg'},
         {path: '/data/today', type:'sap.ui.model.type.Date', constraints:
{displayFormat:'Date'}},
         {path: '/data/tomorrow', type:'sap.ui.model.type.Date', constraints:
{displayFormat:'Date'}}
      ], formatter: '.formatMessage'}}" />
...
</mvc:View>
<!-- Controller -->
sap.ui.define(["sap/base/strings/formatMessage"], function(formatMessage) {
   sap.ui.controller("sample.App", {
      onInit: function() {
         ...
      },
      formatMessage : formatMessage,
      ...
   });
});
```

Property Metadata Binding

The extended syntax makes it possible to access the metadata for certain properties of an entity in OData services, such as heading, label, and precision.

The extended data binding syntax is only valid for `PropertyBindings`. The annotations can be addressed either absolute or relative to a data path.

The consumption of label and description within an application is an example for a possible integration. Instead of copying the corresponding label text to a properties file, which in turn will be translated, a developer can bind a label against the label metadata field for the respective input field.

The binding must know the metadata part of the binding expression. The path to metadata must therefore start with `/#`.

- Absolute bindings
  An absolute binding path starts with the entity name followed by the property name. Property attributes can be accessed with `@` + `propertyName`, nodes can be accesses with the node name only.
  Example:

```
var myLabel = new sap.m.Label({text:"{/#Company/CompanyName/@sap:label}"});
```

- Relative bindings
  A relative binding path can be resolved relative to a data path/context.
  Example:

```
var myLabel = new sap.m.Label({text:"{/Companies(1)/CompanyCode/
#@sap:label}"});
var myLabel2 = new sap.m.Label({text:"{City/#@sap:label}"});
myLabel2.bindElement("Companies(1)");
```

Examples for Data Binding in Different View Types

Examples how complex syntax can be used for calculated fields in XML, HTML, and JS views.

XML View (Recommended)

```
<mvc:View controllerName="testdata.complexsyntax" xmlns:core="sap.ui.core"
    xmlns:mvc="sap.ui.core.mvc" xmlns="sap.ui.commons" xmlns:table="sap.ui.table"
    xmlns:html="http://www.w3.org/1999/xhtml">
    <html:h2>
        <Label text="Hello Mr. {path:'/singleEntry/firstName',
formatter:'.myFormatter'}, {/singleEntry/lastName}"></Label>
    </html:h2>
    <table:Table rows="{/table}">
```

```
        <table:columns>
            <table:Column>
                <Label text="Name"></Label>
                <table:template>
                    <TextField value="{path:'gender',
formatter:'.myGenderFormatter'} {firstName}, {lastName}"></TextField>
                </table:template>
            </table:Column>
            <table:Column>
                <Label text="Birthday"></Label>
                <table:template>
                    <TextField value="{parts:[{path:'birthday/day'},
{path:'birthday/month'},{path:'birthday/year'}],
formatter:'my.globalFormatter'}"></TextField>
                </table:template>
            </table:Column>
        </table:columns>
    </table:Table>
    <html:h2>
        <Label text="A type test: {path:'/singleEntry/amount',
type:'sap.ui.model.type.Float', formatOptions: { minFractionDigits: 1}} EUR"></
Label>
    </html:h2>
</mvc:View>
```

HTML View

```
<template data-controller-name="testdata.complexsyntax">
    <div>
        <h2><div data-sap-ui-type="sap.ui.core.HTML" id="MyHTMLControl" data-
content="<div>Hello Mr. {/singleEntry/firstName}, {/singleEntry/lastName}</
div>"></div></h2>
        <div data-sap-ui-type="sap.ui.table.Table" id="MyTable" data-rows="{/
table}">
            <div data-sap-ui-aggregation="columns">
                <div data-sap-ui-type="sap.ui.table.Column">
                    <div data-sap-ui-type="sap.ui.commons.Label" data-
text="Name"></div>
                    <div data-sap-ui-aggregation="template">
                        <div data-sap-ui-type="sap.ui.commons.TextField" data-
value="{firstName}, {lastName}"></div>
                    </div>
                </div>
                <div data-sap-ui-type="sap.ui.table.Column">
                    <div data-sap-ui-type="sap.ui.commons.Label" data-
text="Birthday"></div>
                    <div data-sap-ui-aggregation="template">
                        <div data-sap-ui-type="sap.ui.commons.TextField" data-
value="{parts:[{path:'birthday/day'},{path:'birthday/month'},{path:'birthday/
year'}], formatter:'my.globalFormatter'}"></div>
                    </div>
                </div>
            </div>
        </div>
        <h2><div data-sap-ui-type="sap.ui.commons.Label" id="MyLabelType" data-
text="A type test: {path:'/singleEntry/amount', type:'sap.ui.model.type.Float',
formatOptions: { minFractionDigits: 1}} EUR"></div></h2>
    </div>
</template>
```

JS View

A JS view is not declarative view, but you may use the same syntax as in XML- and HTMLView, just do not forget to pass a controller instance as a parameter:

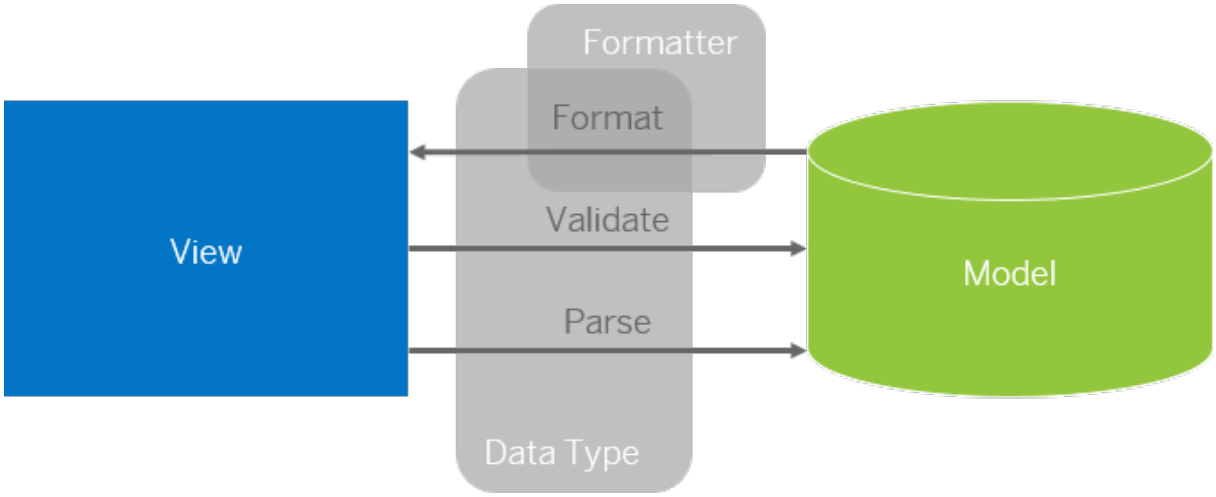
```
sap.ui.jsview("testdata.complexsyntax", {

    getControllerName: function() {
        return "testdata.complexsyntax";
    },
    /**
     *
     * @param oController may be null
     * @returns {sap.ui.cre.Control}
     */
    createContent: function(oController) {
        var c = sap.ui.commons;
        var aControls = [];
        var oLabel = new c.Label({text:"Hello Mr. {path:'/singleEntry/
firstName', formatter:'.myFormatter'}, {/singleEntry/lastName}"}, oController);
        aControls.push(oLabel);

        var oTable = new sap.ui.table.Table({rows:"{/table}"});
        var oColumn = new sap.ui.table.Column();
        var oLabel2 = new c.Label({text:"Name"});
        var oTextField = new c.TextField({value:"{path:'gender',
formatter:'.myGenderFormatter'} {firstName}, {lastName}"}, oController);
        oColumn.setLabel(oLabel2);
        oColumn.setTemplate(oTextField);
        oTable.addColumn(oColumn);
        aControls.push(oTable);
        var oLabel2 = new c.Label({text:"{path:'/singleEntry/amount',
type:'sap.ui.model.type.Float'}"});
        aControls.push(oLabel2);
        return aControls;
    }
});
```

Formatting, Parsing, and Validating Data

Data that is presented on the UI often has to be converted so that is human readable and fits to the locale of the user. On the other hand, data entered by the user has to be parsed and validated to be understood by the data source. For this purpose, you use formatters and data types.



- Views [page 787]
- Models [page 882]

Formatters are used to define the formatting of data on the UI while data types work in both directions: they format the data on the UI and parse and validate user input that is entered.

You can either use standard formatters and data types or define your own custom objects. SAPUI5 provides standard formatter classes that can be used to define custom data types and custom formatters.

If an error occurs during formatting or parsing, the following exception occurs: `sap/ui/model/FormatException` / `sap/ui/model/ParseException`.

> **i** Note
>
> For some controls like `sap/m/Input` you can also use API properties that define the data type and add additional features like restricted input options, for example, `<Input type="Number"/>`.

Formatters

A simple formatter can be defined directly in the controller. For example, you can format name data with the first letter in upper case:

```
myFormatter: function(sName) {
    return sName.charAt(0).toUpperCase() + sName.slice(1);
}
```

> **i Note**
>
> We recommend to use a separate `formatter.js` file that groups the formatters and makes them globally available in your app. You can then load the formatters in any controller by defining a dependency and instantiating the formatter file in a `formatter` variable. For more information, see Step 23: Custom Formatters [page 128] in the *Walkthrough* tutorial.

When the formatter is defined in the controller, you can use it, for example, in an XML view:

```
<Text text="{
    path : 'person/name',
    formatter : '.myFormatter'
}" />
```

> **i Note**
>
> You can also use predefined formatter functions for standard uses cases, like `formatMessage` from module `sap/base/strings/formatMessage`.

> **⚠ Caution**
>
> The automatic type determination for OData V4 interacts with `targetType` and can, thus, influence a formatter's input values. For more information on type determination in OData V4, see Type Determination [page 931].

Data Types

Simple Types

If you also want to validate and parse input values, you use data types. All data types inherit from the abstract `sap.ui.model.Type` class.

A subclass of this class is `sap.ui.model.SimpleType`. The currently available types inherit from `SimpleType` class.

For simple data types, you can generate the following parameters in the constructor:

- `formatOptions`: Format options define how a value is formatted and displayed in the UI.
- `constraints`: Constraints are optional and define how an input value entered in the UI should look like. During parsing the value is validated against these constraints. For example, an `Integer` type has a constraint for `maximum` that is automatically validated when parsing the input values.

```
<Input value="{
    path: '/number',
    type: 'sap.ui.model.type.Integer',
    formatOptions: {
        minIntegerDigits: 3
    },
        constraints: {
    maximum: 1000
    }
}" />
```

For a complete list of all simple types, see API Reference: `sap.ui.model.Type`.

OData Types

These types support OData V2 and V4 including relevant property facets as constraints. The OData types represent the OData EDM primitive types. For more information, see Primitive Data Types in the OData documentation .

For a complete list of all OData types, see API Reference: `sap.ui.model.odata.type`.

> **i Note**
>
> Also see the information on automatic type determination in OData V4 under Type Determination [page 931].

Custom Data Types

You can also define a custom data type based on `sap.ui.model.SimpleType` by specifying a custom implementation for `formatValue`, `parseValue`, and `validateValue`:

```
sap.ui.define([
    "sap/ui/model/SimpleType"
], function (SimpleType) {
    "use strict";
    return SimpleType.extend("sap.ui.demo.myCustomType", {
        formatValue: ...
        parseValue: ...
        validateValue: ...
    });
});
```

> **Example**
>
> Step 5: Adding a Flag Button [page 389] of the *Testing* tutorial shows how to implement a custom data type.

Related Information

Binding Syntax [page 840]

Simple Data Types

For a complete list of all simple types, see API Reference: `sap.ui.model.Type`.

sap.ui.model.type.Boolean

The `Boolean` data type represents a string.

The source value (value given in the model) must be given as boolean and is transformed into the type of the bound control property:

- `boolean`: No transformation needed
- `string`: "true" or "X" are interpreted as true, "false" and "" as false

The `Boolean` type has **no** format or validation constraint options.

Example how a `Boolean` type can be initialized:

```
// "TypeBoolean" required from module "sap/ui/model/type/Boolean"
// The source value is given as boolean.
var oType = new TypeBoolean();
```

sap.ui.model.type.Date

The `Date` data type represents a date (without time).

This type transforms a source value (given value in the model) into a formatted date string and the other way round.

The format patterns must be defined in LDML Date Format notation. For the output, the use of a style ("short, "medium", "long" or "full") instead of a pattern is preferred, as it will automatically use a locale-dependent date pattern.

Examples how a `Date` type can be initialized:

```
// "TypeDate" required  from "sap/ui/model/type/Date"
// The source value is given as Javascript Date object. The used output pattern
depends on the locale settings (default).
var oType = new TypeDate();
// The source value is given as Javascript Date object. The used output pattern
is "yy-MM-dd": e.g. 09-11-27
oType = new TypeDate({pattern: "yy-MM-dd"});
// The source value is given as string in "yyyy/MM/dd" format. The used output
style is "long". The styles are language dependent.
// The following styles are possible: short, medium (default), long, full
// This might be the common use case.
oType = new TypeDate({source: {pattern: "yyyy/MM/dd"}, style: "long"});
// The source value is given as string in "yyyy/MM/dd" format. The used output
pattern is "EEEE, MMMM d, yyyy": e.g. Saturday, August 22, 2043
oType = new TypeDate({source: {pattern: "yyyy/MM/dd"}, pattern: "EEEE, MMMM d,
yyyy"});
// The source value is given as timestamp. The used output pattern is
"dd.MM.yyyy": e.g. 22.12.2010
oType = new TypeDate({source: {pattern: "timestamp"}, pattern: "dd.MM.yyyy"});
// The source value is given as string. The used input pattern depends on the
locale settings (default). The used output pattern is "dd '|' MM '|' yyyy": e.g.
22 | 12 | 2010
oType = new TypeDate({source: {}, pattern: "dd.MM.yyyy"});
```

The `Date` type supports the following validation constraints:

- `maximum` (expects a date presented in the source-pattern format)
- `minimum` (expects a date presented in the source-pattern format)

sap.ui.model.type.DateTime

The `DateTime` data type represents an exact point of time (date and time).

This data type transforms a source value (given value in the model) into a formatted date+time string and the other way round.

The format patterns must be defined in LDML Date Format notation. For the output, the use of a style ("short, "medium", "long" or "full") instead of a pattern is preferred, as it will automatically use a locale-dependent date and time pattern.

> ⚠ Caution
>
> When talking about exact points in time, time zones are imported. The formatted output of the `DateTime` type currently shows the "local" time which equals the time settings of the machine on which the browser runs. If the source value is given as a JavaScript Date object or as a timestamp, the exact moment is sufficiently defined. For string source values this value is interpreted in "local" time if it does not explicitly have a time zone. Currently, all accepted time zone notations must be based on GMT/UTC.

Examples how a `DateTime` type can be initialized:

```
// "TypeDateTime" required from "sap/ui/model/type/DateTime"
// The source value is given as JavaScript Date object. The used output pattern
depends on the locale settings (default).
var oType = new TypeDateTime();
// The source value is given as JavaScript Date object. The used output pattern
is "yyyy/MM/dd HH:mm:ss": e.g. 2011/04/11 09:11:27
oType = new TypeDateTime({pattern: "yyyy/MM/dd HH:mm:ss"});
// The source value is given as string in "yyyy/MM/dd HH:mm:ss" format. The used
output style is "full". The styles are language dependent.
// The following styles are possible: short, medium (default), long, full
// This usecase might be the common one.
oType = new TypeDate({source: {pattern: "yyyy/MM/dd HH:mm:ss"}, style: "full"});
// The source value is given as string in "dd.MM.yyyy HH:mm:ss" format (no
timezone given). The used output pattern is "MMMM d, yyyy, HH:mm:ss.SSS": e.g.
August 22, 2043, 18:48:48.374
oType = new TypeDateTime({source: {pattern: "dd.MM.yyyy HH:mm:ss"}, pattern:
"MMMM d, yyyy, HH:mm:ss.SSS"});
// The source value is given as timestamp. The used output pattern is
"dd.MM.yyyy HH:mm": e.g. 22.12.2010 13:15
oType = new TypeDateTime({source: {pattern: "timestamp"}, pattern: "dd.MMM.yyyy
HH:mm"});
// The source value is given as string. The used input pattern depends on the
locale settings (default). The used output pattern is "hh-mm-ss '/' yy-MM-dd":
e.g. 06-48-48 / 43-08-22
oType = new TypeDateTime({source: {}, pattern: "hh-mm-ss '/' yy-MM-dd"});
// The source value is given as string in "dd.MM.yyyy HH:mm:ss X" format
(timezone is defined in ISO8601 format, e.g. "+02:00"). The used output pattern
depends on the locale settings (default).
oType = new TypeDateTime({source: {pattern: "dd.MM.yyyy HH:mm:ss X"}});
// The source value is given as string in "dd.MM.yyyy HH:mm:ss Z" format
(timezone is defined in RFC822 format, e.g. "+0200"). The used output pattern
depends on the locale settings (default).
oType = new TypeDateTime({source: {pattern: "dd.MM.yyyy HH:mm:ss Z"}});
```

```
// The source value is given as string in "dd.MM.yyyy HH:mm:ss z" format
(timezone is currently defined as e.g. "GMT+02:00", "UTC+02:00", "UT+02:00" or
"Z" (shortcut for "UTC+00:00")).
// The used output pattern depends on the locale settings (default).
oType = new TypeDateTime({source: {pattern: "dd.MM.yyyy HH:mm:ss z"}});
```

The `DateTime` type supports the following validation constraints:

- `maximum` (expects a `dateTime` presented in the source-pattern format)
- `minimum` (expects a `dateTime` presented in the source-pattern format)

sap.ui.model.type.Float

The `Float` data type represents a float value.

The source value for this data type, that is, the value given in the model must be given as a number and is transformed into the type of the bound control property:

- `float`: No transformation needed
- `integer`: Value is rounded using `Math.floor`
- `string`: Value is formatted or parsed according to the given output pattern

Examples how a `Float` type can be initialized:

```
// "TypeFloat" required from module "sap/ui/model/type/Float"
// The source value is given as JavaScript number. Output is transformed into
the type of the bound control property.
// If this type is "string" (e.g. the value property of the TextField control)
the used default output pattern parameters depend on locale and fixed settings.
var oType = new TypeFloat();
// The source value is given as JavaScript number. Output is transformed into
the type of the bound control property.
// If this type is "string" (e.g. the value property of the TextField control)
the given output pattern is used (parameters which are not specified are taken
from the default pattern)
oType = new TypeFloat({
  minIntegerDigits: 1, // minimal number of non-fraction digits
  maxIntegerDigits: 99, // maximal number of non-fraction digits
  minFractionDigits: 0, // minimal number of fraction digits
  maxFractionDigits: 99, // maximal number of fraction digits
  groupingEnabled: true, // enable grouping (show the grouping separators)
  groupingSeparator: ",", // the used grouping separator
  decimalSeparator: "." // the used decimal separator
});
```

The `Float` type supports the following validation constraints:

- maximum
- minimum

sap.ui.model.type.Integer

The `Integer` data type represents an integer value.

The source value for this data type, that is, the value given in the model, must be given as a number and is transformed into the type of the bound control property:

- `float`: Value is rounded using `Math.floor`
- `integer`: No transformation needed
- `string`: Value is formatted or parsed according to the given output pattern

Examples how an `Integer` type can be initialized:

```
// "TypeInteger" required from module "sap/ui/model/type/Integer"
// The source value is given as JavaScript number. Output is transformed into
the type of the bound control property.
// If this type is "string" (e.g. the value property of the TextField control)
the used default output pattern parameters depend on locale and fixed settings.
var oType = new TypeInteger();
// The source value is given as JavaScript number. Output is transformed into
the type of the bound control property.
// If this type is "string" (e.g. the value property of the TextField control)
the given output pattern is used (parameters which are not specified are taken
from the default pattern)
oType = new TypeInteger({
  minIntegerDigits: 1, // minimal number of non-fraction digits
  maxIntegerDigits: 99, // maximal number of non-fraction digits
  minFractionDigits: 0, // minimal number of fraction digits
  maxFractionDigits: 0, // maximal number of fraction digits
  groupingEnabled: false, // enable grouping (show the grouping separators)
  groupingSeparator: ",", // the used grouping separator
  decimalSeparator: "." // the used decimal separator
});
```

The `Integer` type supports the following validation constraints:

- maximum
- minimum

sap.ui.model.type.String

The `String` data type represents a string.

The source value (value given in the model) must be given as a number and is transformed into the type of the bound control property:

- `string`: No transformation needed
- `integer/float`: String is parsed accordingly
- `boolean`: "true" or "X" are interpreted as true, false, and " " as false

The `string` type does not have any format options.

Example how a `String` type can be initialized:

```
// "TypeString" required from module "sap/ui/model/type/String"
// The source value is given as string. The length of the string must not be
greater than 5.
```

```
var oType = new TypeString(null, {maxLength: 5});
```

The `String` type supports the following validation constraints:

- `maxLength` (expects an integer number)
- `minLength` (expects an integer number)
- `startsWith` (expects a string)
- `startsWithIgnoreCase` (expects a string)
- `endsWith` (expects a string)
- `endsWithIgnoreCase` (expects a string)
- `contains` (expects a string)
- `equals` (expects a string)
- `search` (expects a regular expression)

For more information, see API Reference: `sap.ui.model.type.String`.

sap.ui.model.type.Time

The `Time` data type represents a time (without date).

This type transforms a source value (given value in the model) into a formatted time string and the other way round.

The format patterns must be defined in LDML Date Format notation. For the output, the use of a style ("short, "medium", "long" or "full") instead of a pattern is preferred, as it will automatically use a locale dependent time pattern.

Examples how a `Time` type can be initialized:

```
// "TypeTime" required from module "sap/ui/model/type/Time"
// The source value is given as JavaScript Date object. The used output pattern
depends on the locale settings (default).
var oType = new TypeTime();
// The source value is given as JavaScript Date object. The used output pattern
is "hh-mm-ss": e.g. 09-11-27
oType = new TypeTime({pattern: "hh-mm-ss"});
// The source value is given as string in "hh-mm-ss" format. The used output
style is "short". The styles are language dependent.
// The following styles are possible: short, medium (default), long, full
// This might be the common use case.
oType = new TypeTime({source: {pattern: "hh-mm-ss"}, style: "short"});
// The source value is given as string in "hh/mm/ss/SSS" format. The used output
pattern is "HH:mm:ss '+' SSS 'ms'": e.g. 18:48:48 + 374 ms
oType = new TypeTime({source: {pattern: "hh/mm/ss/SSS"}, pattern: "HH:mm:ss '+'
SSS 'ms'"});
// The source value is given as timestamp. The used output pattern is "HH
'Hours' mm 'Minutes'": e.g. 18 Hours 48 Minutes
oType = new TypeTime({source: {pattern: "timestamp"}, pattern: "HH 'Hours' mm
'Minutes'"});
// The source value is given as string. The used input pattern depends on the
locale settings (default). The used output pattern is "hh:mm a": e.g. 06:48 PM
oType = new TypeTime({source: {}, pattern: "hh:mm a"});
```

The `Time` type supports the following validation constraints:

- `maximum` (expects a time presented in the source-pattern format)
- `minimum` (expects a time presented in the source-pattern format)

sap.ui.model.type.DateTimeInterval

The interval data types represent intervals between two date/time related properties.

Three new types are used to format two date related properties from a model for displaying in the UI. Additionally they are used to parse and validate the values in UI controls before they are saved back to the model. All of the them are subtypes of `sap.ui.model.CompositeType` and are supposed to be set with a composite binding. The new interval types are:

- `sap.ui.model.type.DateInterval` - represents a date interval (without time) which transforms the source values into a formatted date interval string and the other way around.
- `sap.ui.model.type.DateTimeInterval` - represents a date interval with the exact point of time (date and time) which transforms the source values into a formatted date+time interval string and the other way around
- `sap.ui.model.type.TimeInterval` - represents a time interval (without date) which transforms the source values into a formatted time interval string and the other way around

Usage with JSON, OData V2 or V4 models

> **i** Note
>
> The new date interval types can be used together with different types of model. However, there are some differences in the usage when the new date interval types get used with a JSON, OData V2 or V4 model.

The interval types need two JavaScript `Date` objects from the sub-bindings to format them as a date interval string. If the values which come from the sub-binding aren't instances of JavaScript `Date` object, they need to be converted to JavaScript `Date` objects before they are forwarded to the date interval types. The conversion can be done by setting a corresponding type on the sub-binding and this type knows how the value which comes directly from the model can be converted to a JavaScript `Date` object. A date interval type works together with the types on the sub-bindings to get the original value from the model converted to a JavaScript `Date` object.

> **!** Restriction
>
> One exception is with the OData V2 Model. Although the date fields are saved as string in the model, they get converted to JavaScript `Date` objects by the open source library which is used in `v2.ODataModel`. Therefore it's not needed to set an extra type on the sub-binding when the date interval types are used together with the OData V2 model.

The following example shows how this should be setup with a `sap/m/Table` which is bound to an OData V4 model. The table consists of four different columns whereas the `StartsAt` and `EndsAt` represent date field as string with Edm type `Edm.DateTimeOffset`. The date interval formatting is done by combining these two date fields together.

In order to let the date interval type correctly, get two JavaScript `Date` objects from the sub-bindings, a type `sap.ui.model.odata.type.DateTimeOffset` is set on each sub-binding to convert the date string into a JavaScript `Date` object.

```
// "ODataModel" required from module "sap/ui/model/odata/v4/ODataModel"
// "Table" required from module "sap/m/Table"
// "Text" required from module "sap/m/Text"
// "Column" required from module "sap/m/Column"
// "ColumnListItem" required from module "sap/m/ColumnListItem"
var urlV4 = "/databinding/proxy/http/services.odata.org/TripPinRESTierService/
(S(kqyippfvpypubsah2zi1enbi))/";
// Some OData V4 model configuration
var oModelConfig = {
    groupId : "$direct",
    serviceUrl: urlV4,
    synchronizationMode: "None",
    operationMode: "Server"
};
var oModel = new ODataModel(oModelConfig);
var oTable = new Table({
    growing: true,
    columns : [
        new Column({header: new Text({text: "Name"})}),
        new Column({header: new Text({text: "StartsAt"})}),
        new Column({header: new Text({text: "EndsAt"})}),
        new Column({header: new Text({text: "Interval"})}),
    ]
});
oTable.setModel(oModel);
oTable.bindItems({
    path:"/People('russellwhyte')/Trips",
    template: new ColumnListItem({
        cells: [
           new Text({text:"{Name}"}),
            new Text({text:"{StartsAt}"}),
            new Text({text:"{EndsAt}"}),
            new Text({text:{
                parts:[
                    {
                        path:'StartsAt',
                        // requires OData type to convert the date
                        // string into JavaScript Date object
                        type: "sap.ui.model.odata.type.DateTimeOffset"
                    },{
                        path:'EndsAt',
                        // requires OData type
                        type: "sap.ui.model.odata.type.DateTimeOffset"
                    }
                ],
                type: 'sap.ui.model.type.DateInterval',
                formatOptions: {format: "yMMMdd"}
            }})
        ]
    })
});
```

Formatter Classes

For a complete list of all formatter classes, see API Reference: `sap.ui.model.Type`.

Date Format

The `sap.ui.core.format.DateFormat` class can be used to parse a string representing a date, time, or the combination of date and time into a JavaScript date object and vice versa (also known as format). `DateFormat` formats and parses date and time values according to a set of format options. It can also be used to format intervals. A pattern base on Locale Data Markup Language (LDML) date format notation can be given and the date is formatted following the given pattern. `DateFormat` can also format the date and time into relative values on "day" level.

Instantiation

You instantiate of `sap.ui.core.format.DateFormat` by calling the `getter` defined on the `DateFormat` (and not by calling the constructor):

```
var oDateFormat = sap.ui.core.format.DateFormat.getDateInstance();
// or
var oDateTimeFormat = sap.ui.core.format.DateFormat.getDateTimeInstance();
// or
var oTimeFormat = sap.ui.core.format.DateFormat.getTimeInstance();
```

Parameters

There are several parameters which affect the final result of formatting and parsing a date. If no parameter is set, the default setting defined in the current locale is used to format and parse the date.

Date Pattern

`format` (recommended):

The format string does contain pattern symbols (e.g. `yMMMd` or `Hms`) and will be converted into the pattern in the used locale, which matches the wanted symbols best.

The symbols must be in canonical order, that is: Era (`G`), Year (`y/Y`), Quarter (`q/Q`), Month (`M/L`), Week (`w/W`), Day-Of-Week (`E/c`), Day (`d/D`), Hour (`h/H/k/K`), Minute (`m`), Second (`s`), Timezone (`z/Z/v/V/O/X/x`).

```
var oFormat = sap.ui.core.format.DateFormat.getInstance({
    format: "yMMMd"
});
oFormat.format(new Date()); //string in locale de "29. Jan. 2017"; string in
locale en "Jan 29, 2017"
```

`pattern`: A date pattern in LDML date format notation. The date is formatted based on the given pattern.

```
var oDateFormat = sap.ui.core.format.DateFormat.getDateInstance({
    pattern: "EEE, MMM d, yyyy"
});

var oNow = new Date();
oDateFormat.format(oNow); //string in the same format as "Thu, Jan 29, 2017"
```

> **i Note**
>
> If you define `format` and `pattern`, the `format` will be ignored!

The letters which can be included in this pattern are explained in the following table:

Table 25: Patterns

Letter	Replaced By
`G`	era string for the current date
`y`	year
`Y`	Same as `y`, but uses the ISO year-week calendar
`M`	month
`L`	month in stand-alone format
`w`	week number in year
`(W)`	(currently not supported) week number in month
`(D)`	(currently not supported) day number in year
`d`	day number in month
`Q`	quarter number
`q`	quarter number in stand-alone format
`(F)`	(currently not supported) day of week in month
`E`	day of week
`c`	day of week in stand-alone format
`u`	day number of week
`a`	AM or PM
`j`	Can only be used in the `format` option, not in the `pattern`. It will be replaced by `h`, `H`, `K` or `k` depending on the locale preferred time cycle type (12-hour or 24-hour).

Letter	Replaced By
J	Can only be used in the format option, not in the pattern. It will be replaced by h, H, K or k. However unlike j it requests no dayPeriod marker such as "am" or "pm". It is typically used where there is enough context that the day period not necessary. For example, with jmm, "18:00" could appear as "6:00 PM", while with Jmm, it would appear as "6:00" (no PM).
H	hour (0-23)
k	hour (1-24)
K	hour (0-11)
h	hour (1-12)
m	minute
s	second
S	fractional second
z	time zone
Z	time zone in RFC 822 format
X	time zone in ISO 8601 format

Style

This can be set with either empty, short, medium or long. If no pattern is given, a locale-dependent default date pattern of that style is used which is extracted from the current locale.

If in addition to style pattern or format is defined, the style is ignored.

If you use the datetime instance by calling getDateTimeInstance, you can define different styles for date and time. For example, medium/short defines medium style for the date and short style for the time.

Relative Format

Relative format on "day"' level is only supported by the date instance but not the date time or the time instance.

- relative: if this is set to true, the date is formatted relatively to the actual date if it's within the given date range.
- relativeRange: the day range used for relative formatting. The default is set to 6 which means only dates within the last six days, the acutal date, and the next six days are formatted relatively.
- relativeScale: the relative scale is chosen depending on the difference between the given date and now, possible relative scales are: year, month, week, day, hour, minute, second, and auto
  If auto is set, the scale is chosen dependent on the actual difference.

Interval

`interval`: If this is set to `true`, the `DateFormat` is capable to format two dates as an interval. The `format` method expects an array with two dates as the first argument.

If the format option is set with necessary symbols, the `DateFormat` displays the fields which have the same value between the two dates only once in the result string. For example, the interval "Jan 10, 2008 - Jan 12, 2008" will be formatted as "Jan 10-12, 2008". Otherwise the two given dates are formatted separately and concatenated with locale-dependent pattern.

```
var oFormat = sap.ui.core.format.DateFormat.getInstance({
    format: "yMMMd",
    interval: true
});
var oDate1 = new Date(2017, 3, 11);
var oDate2 = new Date(2017, 4, 11);
oFormat.format([oDate1, oDate2]);
// string in locale de "11. Apr. – 11. Mai 2017";
// string in locale en "Apr 11 – May 11, 2017"
```

Parsing

`strictParsing`: If this is set to `true`, the `date` string is validated during parsing. If it doesn't pass the validation, `null` is returned.

```
var oDateFormat = sap.ui.core.format.DateFormat.getDateInstance({
    relative: true
});

var nMS = 1000 * 60 * 60 * 24; //milliseconds in a day
var oNow = new Date();
var oDate = new Date(oNow.getTime() - nMS);
oDateFormat.format(oDate); //returns yesterday

oDate = new Date(oNow.getTime() + 7 * nMS);
oDateFormat.format(oDate); //isn't returned in relative format because the
default value of relativeRange is [6|-6,]
```

Related Information

API Reference: `sap.ui.core.format.DateFormat`

Number Format

The `sap.ui.core.format.NumberFormat` class can be used to parse a string representing a number (float or integer) into a JavaScript `number` and vice versa (also known as `format`).

`NumberFormat` uses the parameters defined for the current locale. These parameters can be overwritten on each instance by setting the format options.

There are four types of formatters defined in `NumberFormat`:

- Integer formatter: formats and parses only the integer digits; decimal digits are ignored

- Float formatter: formats and parses both integer and decimal digits.
- Percent formatter: formats the number into a string with percentage sign. It validates the number whether it contains the right percentage sign in its parser.
- Currency formatter: formats the number by using the parameters defined for the given currency code. Either currency symbol, currency code, or none of both can be included in the final formatted string. It parses the given string into an array which contains both the currency number and currency code.

Instantiation

The instantiation of `sap.ui.core.format.NumberFormat` is done by calling `getter` defined on `NumberFormat` (and not by using the constructor).

```
var oIntegerFormat = sap.ui.core.format.NumberFormat.getIntegerInstance();
// or
var oFloatFormat = sap.ui.core.format.NumberFormat.getFloatInstance();
// or
var oPercentFormat = sap.ui.core.format.NumberFormat.getPercentInstance();
// or
var oCurrencyFormat = sap.ui.core.format.NumberFormat.getCurrencyInstance();
```

Parameters

All parameters have their default value defined in the current locale. Therefore, if no parameter is given when instantiating the formatter instance, it fetches the parameters from the current locale. All parameters can be overwritten by giving a format option object in the `getter` of the formatter. There are a bunch of parameter defined for the four types of formatters. Most of them are shared among the types and the rest are specifically defined for a certain kind of formatter.

Integer and Decimal Digits

- `minIntegerDigits`: minimal number of non-fraction digits. If there are less integer digits in the number than the value here, `'0'(s)` is prepended in the final result.
- `maxIntegerDigits`: maximal number of non-fraction digits. If there are more digits in the number than the value here, all integer digits in the final result are replace by `?`.
- `minFractionDigits`: minimal number of fraction digits. If there are less decimal digits in the number than the value here, '0'(s) is appended in the final result.
- `maxFractionDigits`: maximal number of fraction digits. If there are more decimal digits in the number than the value here, those digits are discarded from the result and the least significant digit is calculated by using the given `roundingMode` parameter.
- `decimals`: number of decimal digits in the final result. Same result is achieved by setting both `minFractionDigits` and `maxFractionDigits` to this value.
- `precision`: number of digits used to display the number, for example with precision 5 a number could be 1.3456 or 134.45.

- `shortDecimals`: number of decimal digits in the shortifed number when parameter `style` is set to `short` or `long`. If this isn't set, the parameter `decimal` is used instead.

```
// Locale object is created and set to the format in order to have a user locale
independent formatter.
// In most of the cases, this locale object isn't needed.
var oLocale = new sap.ui.core.Locale("en-US");
var oFormatOptions = {
    minIntegerDigits: 3,
    maxIntegerDigits: 5,
    minFractionDigits: 2,
    maxFractionDigits: 4
};
var oFloatFormat =
sap.ui.core.format.NumberFormat.getFloatInstance(oFormatOptions, oLocale);
oFloatFormat.format(1.1); // returns 001.10
oFloatFormat.format(1234.567); // returns 1,234.567
oFloatFormat.format(123456.56789); // returns ??,???.5679
```

```
// Locale object is created and set to the format in order to have a user locale
independent formatter.
// In most of the cases, this locale object isn't needed.
var oLocale = new sap.ui.core.Locale("en-US");
var oFormatOptions = {
    style: "short",
    decimals: 1,
    shortDecimals: 2
};
var oFloatFormat =
sap.ui.core.format.NumberFormat.getFloatInstance(oFormatOptions, oLocale);
oFloatFormat.format(1234.56); // returns 1.23K (shortified number takes the
shortDecimals parameter)
oFloatFormat.format(123.456); // returns 123.5 (non-shortified number takes the
decimals parameter)
```

Separator and Signs

- `groupingEnabled` defines whether the integer digits are put into groups which are separated by the `groupingSeparator` parameter
- `groupingType` defines the type of grouping. Either `Arabic` or `Indian` can be set here.
- `groupingSeparator` defines the separator of grouping.
- `decimalSeparator` defines the symbol of decimal point.
- `groupingSize` only used if you don't want the locale-dependent grouping, for example 3 digits for de or en
- `groupingBaseSize` only used if your locale uses a specific group size for the first group (like Indian), and you don't want to use the standard
- `plusSign`
- `minusSign`

Compact Format

You can use compact format to format a number using a given scale. For example, 1000000 may be formatted under en-US locale as *1 Million*.

To format a number in compact format, set the option `style` to either `short` or `long`. These styles control which version of scale name is used. For example, 1000000 is formatted as *1M* with `short` and *1 Million* with `long`.

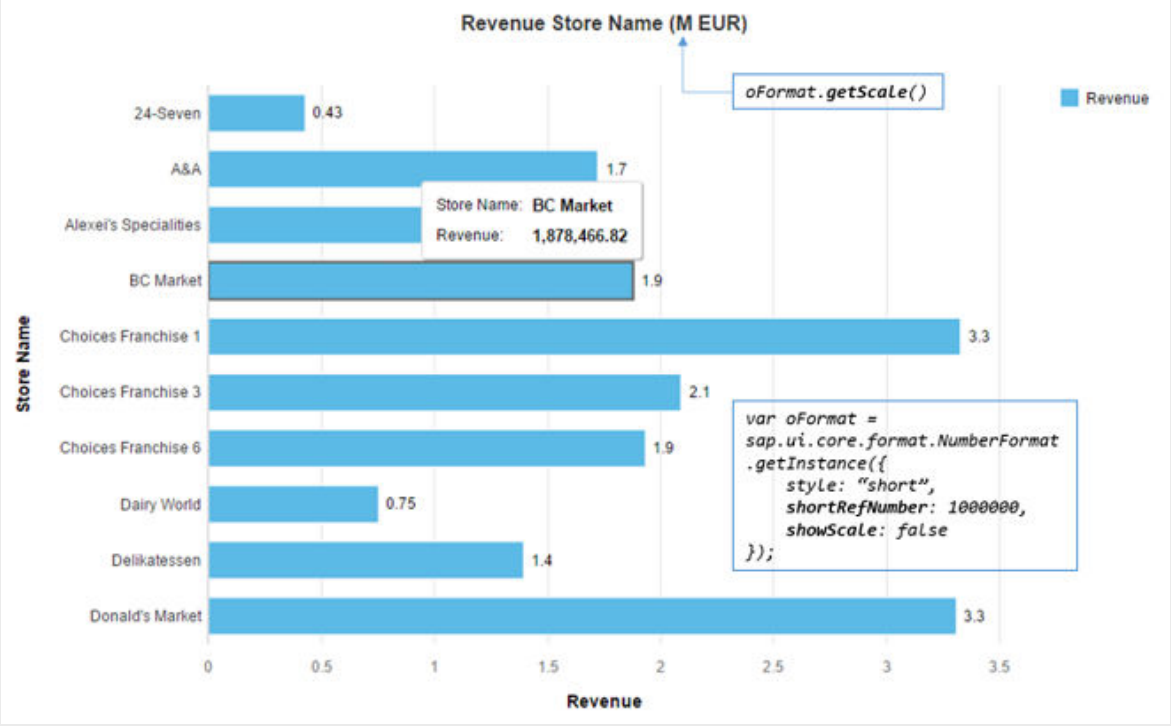
The scale can be selected automatically based on the given number, or you can set it explicitely by using `shortRefNumber`. You can set this option with a number which is then used for calculating the scaling factor for formatting all given numbers to this formatter.

To hide the scaling formatter from the formatted number and only be shown once on the screen, you can use option `showScale`. In order to get the scaling factor name of the number set to `shortRefNumber` under the current running locale, you use method `getScale`.

To control the start the starting point of numbers which should be displyed in compact format, you use `shortLimit`.

Example

In the following chart, all numbers both on the chart and axis should be formatted using the same scaling factor. The scaling factor should only appear in the chart title and be hidden from the formatted number. In order to achieve this, the option `shortRefNumber` is set to `1000000` and `showScale` is set to `false`. The corresponding scaling factor name is returned by calling the `getScale` method.



Miscellaneous

- `emptyString` defines what empty string (`""`) is parsed as and what is formatted as `emptyString`. The allowed values are only `NaN`, `null` or `0`. Default setting is `NaN`.
- `pattern`: a pattern which follows the CLDR syntax. The number is then formatted according to the given pattern.
- `roundingMode`: defines a rounding behavior for discarding the digits after the maximum decimal digits defined by `maxFractionDigits` or `decimals`. Rounding will only be applied, if the formatting value is of type number.

Table 26: Rounding Modes (with decimals parameter set to 1)

Number	FLOOR	CEILING	TOWARDS_ZERO	AWAY_FROM_ZERO	HALF_FLOOR	HALF_CEILING	HALF_TOWARDS_ZERO	HALF_AWAY_FROM_ZERO
2.21	2.2	2.3	2.2	2.3	2.2	2.2	2.2	2.2
2.25	2.2	2.3	2.2	2.3	2.2	2.3	2.2	2.3
2.29	2.2	2.3	2.2	2.3	2.3.	2.3	2.3	2.3
-2.21	-2.3	-2.2	-2.2	-2.2	-2.2	-2.2	-2.2	-2.2
-2.25	-2.3	-2.2	-2.2	-2.3	-2.3	-2.2	-2.2	-2.3
-2.29	-2.3	-2.2	-2.2	-2.3	-2.3	-2.3	-2.3	-2.3

Parsing

Parsing a number

A formatted number which contains a locale-dependent grouping separator, decimal point, or percentage sign can be parsed into a number object using `sap.ui.core.format.NumberFormat`. Those number string may not be correctly parsed by using `parseInt` or `parseFloat` in JavaScript.

```
// Locale object is created and set to the format in order to have a user locale
independent formatter.
// In most of the cases, this locale object isn't needed.
var oLocale = new sap.ui.core.Locale("en-US");
var oFloatFormat = sap.ui.core.format.NumberFormat.getFloatInstance(oLocale);
oFloatFormat.parse("1,234.567"); // returns 1234.567
oFloatFormat.parse("12.34%"); // returns 0.1234
```

Unit Formatting [page 873]
Currency Formatting [page 878]

File Size Format

The `sap.ui.core.format.FileSizeFormat` class can be used to format a number into a string which contains both the number and the most appropriate size unit. It supports all parameters defined in

`sap.ui.core.format.NumberFormat`. It can also parse a file size string with or without unit into a number which represents the same size in unit byte.

Instantiation

The instantiation of `sap.ui.core.format.FileSizeFormat` is done by calling the `getter` defined on the `FileSizeFormat` (and not by calling the constructor):

```
var oFileSizeFormat = sap.ui.core.format.FileSizeFormat.getInstance();
```

Parameters

`binaryFilesize`: if this is set to `true`, base `2` is used which means 1 Kilobyte = 1024 Byte. Otherwise base 10 is used which means 1 Kilobyte = 1000 Byte. The default value is `false`.

```
var oFileSizeFormat =  sap.ui.core.format.FileSizeFormat.getInstance({
    binaryFilesize: true,
    decimals: 2
});

oFileSizeFormat.format(1023); //returns 1,023.00 Bytes because it's smaller than
1 KB (1024 Bytes)

oFileSizeFormat = sap.ui.core.format.FileSizeFormat.getInstance({
    binaryFilesize: false,
    decimals: 2
});
oFileSizeFormat.format(1023); //returns 1.02 KB because it's bigger than 1 KB
(1000 Bytes)
```

Parsing

`FileSizeFormat` can also parse a string which contains both number and unit of a number which represents the same amount of size in unit byte.

```
var oFileSizeFormat =  sap.ui.core.format.FileSizeFormat.getInstance();

oFileSizeFormat.parse("1.23 MiB"); //returns 1289748.48
oFileSizeFormat.parse("1 MB"); // returns 1230000
```

Unit Formatting

SAPUI5 supports the formatting and parsing of units. These unit formats are by default taken from the CLDR. Besides the default units defined in the CLDR, you can also define custom units.

Introduction

Similar to the formatting of currencies, the new unit formatting feature allows you to combine a number value with a localized unit string. Still the actual numbers themselves can be formatted in all kinds of styles, for example, with different decimals or fraction digits.

With version 1.54 all language files will include the CLDR data for formatting. You can check out the public CLDR github repository for an overview of all supported languages and units: https://github.com/unicode-cldr/cldr-units-modern

The default CLDR units include a pattern for formatting a number value in the given unit and the set locale. Additionally, you can now parse an already formatted string back into the unit-format code from the CLDR and of course the raw number value. The same is true for your self-defined custom units.

In addition to the formatting and parsing patterns, the CLDR also provides a display-name for all units, as well as grammatical plural forms. The display-name for the unit `volume-cubic-inch` is *inches³*. The formatting output might however look like this: *12 in³*.

Usage

Simple Sample

Since the units and their formatting patterns are already included in the respective language JSON files, you can simply instantiate a new unit format instance via the `NumberFormat.getUnitInstance()` factory. The resulting instance supports formatting and parsing. While the `FormatOptions` are used to format the Number itself, the specific unit code is passed to the format/parse method.

```
// create a simple unit formatting instance, without any additional options
sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {
   var oUnitFormat = NumberFormat.getUnitInstance();
   oUnitFormat.format(12345.678, "speed-mile-per-hour"); // output: 12,345.678
mph
   oUnitFormat.parse("12345.678 mph"); // output: [12345.678, "speed-mile-per-
hour"]
});
```

Complex Sample

Besides a simple formatting and parsing of units defined in the CLDR, you can also use the known format options for formatting numbers independent of the unit. The style of the number output format can be defined as either `short` or `long`.

Essentially, the new unit formatting can be combined together with the existing number formatting.

```
// new unit formatter, decimals are limited to 2, and the output style is set to
"short"
sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {
   var en = new sap.ui.core.Locale("en");
   var oUnitFormat = NumberFormat.getUnitInstance({decimals:2, style:"short"},
en);
   console.log(oUnitFormat.format(12345.678, "speed-mile-per-hour")); //
output:  12.35K mph
   console.log(oUnitFormat.parse("12.35K mph")); // output: [12350, "speed-mile-
per-hour"]
});
// new unit formatter, decimals are limited to 2, and the output style is set to
"long"
sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {
   var en = new sap.ui.core.Locale("en");
   var oUnitFormat = NumberFormat.getUnitInstance({decimals:2, style:"long"},
en);
   console.log(oUnitFormat.format(12345.678, "speed-mile-per-hour")); // output:
12.35 thousand mph
   console.log(oUnitFormat.parse("12.35 thousand mph")); // output: [12350,
"speed-mile-per-hour"]
});
```

The unit's `displayname` can also be retrieved based on the data from the CLDR.

```
sap.ui.require(["sap/ui/core/format/NumberFormat", "sap/ui/core/Locale", "sap/ui/
core/LocaleData"],
    function(NumberFormat, Locale, LocaleData) {
    console.log(LocaleData.getInstance(new
Locale("en")).getUnitDisplayName("speed-mile-per-hour")); // output: miles/hour
});
```

Plural Forms and RTL

Depending on the set locale/language, the output also correctly regards grammatical plural forms, as well as right-to-left orientation. In some Arabic languages, for example, there is a distinction between "many" and "one", with "one" being a single string without a number in it:

```
sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {
   var ar = new sap.ui.core.Locale("ar");
   var oUnitFormat = NumberFormat.getUnitInstance({decimals:2, style:"long"},
ar);
   console.log(oUnitFormat.format(123456.789, "angle-revolution")); // 123.46 ألف
دورة
   console.log(oUnitFormat.format(1, "angle-revolution")); // دورة
});
```

And here's an example of right-to-left orientation in Hebrew:

```
sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {
   var he = new sap.ui.core.Locale("he");
   var oUnitFormat = NumberFormat.getUnitInstance({decimals:2, style:"long"},
he);
   console.log(oUnitFormat.format(12345.678, "speed-mile-per-hour")); //  12.35
אלף mph
});
```

> **i Note**
>
> The right-to-left languages include a special whitespace character as a marker. This character is of course invisible, but you should take note of it, in case you intend to do string comparisons and other string operations. For example, in the Chrome debugger the RTL mark is visualized as a red dot.

Custom Units

Instance-Exclusive Units

The unit NumberFormat instance also allows you to specify custom units, which can be used for formatting, as well as parsing. All you have to do is add your custom units as an additional parameter in the `NumberFormat.getUnitInstance()` factory.

In the following example, you can see how this is done for a specific instance.

```
sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {

	var oFormat = sap.ui.core.format.NumberFormat.getUnitInstance({
		customUnits: {
			"zomb": {
				"unitPattern-count-one": "{0} Zombie...",
				"unitPattern-count-other": "{0} Zombies!!"
			}
		}
	});

	console.log(oFormat.format(1, "zomb"));     // 1 Zombie...
	console.log(oFormat.format(9001, "zomb"));  // 9.001 Zombies!!

	console.log(oFormat.parse("12 Zombies!!")); // [12, "zomb"];
});
```

> ⚠ Caution
>
> The custom units defined on the number format instance will be exclusive to this instance. No other instances are affected. In addition, once you define custom units for an instance, only those units will be formatted and parsed by that instance. This also means that custom units defined via the Configuration are not taken into account for this specific instance.
>
> This is done to circumvent ambiguities and unit clashes with the CLDR units. So in the above example, only Zombies can be formatted, but no Gigawatt (CLDR key: `power-gigawatt`).
>
> > ✤ Example
> >
> > ```
> > 	// the previous Unit instance is used
> > 	// formatting/parsing Zombies is fine
> > 	console.log(oFormat.format(9001, "zomb"));  // 9.001 Zombies!!
> > 	console.log(oFormat.parse("12 Zombies!!")); // [12, "zomb"];
> >
> > 	// formatting/parsing Giga-Watt does not work (because of the
> > exclusivity of the custom units on the above instance)
> > 	console.log(oFormat.format(1.21, "power-gigawatt")); // "": results
> > in an empty string
> > ```

If you need both, CLDR units and custom units, you simply have to create two separate number format instances.

Globally Configured Units

You can also add custom units via the format settings in the Core configuration. Contrary to the custom units defined exclusively on a single unit-formatter instance, these custom units will be available in ALL unit-formatted instances for the current locale (except if they also define a set of custom units).

Adding a unit with a key which is already available in the CLDR, will overwrite the CLDR unit. This way you can overdefine single units, in case the CLDR provided formatting is not sufficient.

```
sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {
   sap.ui.getCore().getConfiguration().getFormatSettings().addCustomUnits({
       "cats": {
          "displayName": "kitties",
          "unitPattern-count-one": "{0} kitty",
          "unitPattern-count-other": "{0} kitties"
       },
       "dogs": {
          "displayName": "puppies",
          "unitPattern-count-one": "{0} puppy",
          "unitPattern-count-other": "{0} puppies"
       },
       "power-horsepower": { // overwrite of an existing CLDR unit
          "displayName": "Horsepower",
          "unitPattern-count-one": "{0} AmazingHorse", // singular form
          "unitPattern-count-other": "{0} AmazingHorses" // plural form
       }
    });

    var oUnitFormat = NumberFormat.getUnitInstance({decimals:2, style:"long"});

    // formatting a custom unit
    console.log(oUnitFormat.format(12, "cats")); // 12,00 kitties

    // formatting and existing CLDR unit
    console.log(oUnitFormat.format(5, "speed-meter-per-second")); // 5,00 m/s

    // formatting and existing CLDR unit
    console.log(oUnitFormat.format(12, "power-horsepower")); // 12,00
AmazingHorses
});
```

Additionally, you can now define unit mappings, in order to use aliases for some units. A typical use-case is to map from an ISO unit code to a CLDR key. Of course you can also map to custom units as shown below.

```
sap.ui.getCore().getConfiguration().getFormatSettings().addUnitMappings({
   "kitties": "cats", // maps to a custom defined unit
   "mySpeedAlias": "speed-kilometer-per-hour" // maps to an existing the CLDR
unit
});
```

Additional Format Options

When using either instance, exclusive or globally configured custom units, you can also add two additional format options (`decimals` and `precision`) to the custom unit's definition block. In the following examples the `decimals` option is set.

> **Example**
>
> Globally configured custom units:
>
> ```
> sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {
>    // define a new unit called Lux
>    sap.ui.getCore().getConfiguration().getFormatSettings().addCustomUnits({
>        "lux": {
>           "displayName": "Lux",
>           "unitPattern-count-one": "{0} lx",
>           "unitPattern-count-other": "{0} lx",
> ```

```
            "decimals": 2
        }
    });

    var oUnitFormat = NumberFormat.getUnitInstance({style:"long"});

    console.log(oUnitFormat.format(2.4, "lux")); // 2,40 lux (notice the
padded 0 after the 4, this is due to the decimals option)
});
```

Example

Instance exclusive custom unit definition:

```
sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {
    // define a new unit called Lux
    var oFormat = sap.ui.core.format.NumberFormat.getUnitInstance({
        customUnits: {
            "lux": {
                 "displayName": "Lux",
                 "unitPattern-count-one": "{0} lx",
                 "unitPattern-count-other": "{0} lx",
                 "decimals": 2
            }
        }
    });

    var oUnitFormat = NumberFormat.getUnitInstance({style:"long"});

    console.log(oUnitFormat.format(2.4, "lux")); // 2,40 lux (notice the
padded 0 after the 4, this is due to the decimals option)
});
```

Databinding: New Unit Type

Besides the NumberFormat instances, you now can also include the new Unit type in your application. Simply define it as the type for a property binding, and most of the formatting and parsing effort will be handled for you out of the box.

To demonstrate this, we can consider an example with electric meters. Typically they all measure the flow of energy in kilowatt hours (kWh). Yet some meters are more precise than others, some measure up to a few hundred wattseconds, others just cap it at full kilowatt hours. To simplify it for our example: the number of decimals might differ depending on the type of electric meter.

```
// defining a new custom Type as a subclass of the sap.ui.model.type.Unit type
sap.ui.require(["sap/ui/model/type/Unit", "sap/ui/core/format/NumberFormat"],
function(UnitType, NumberFormat) {

       UnitType.extend("sap.ui.core.samples.MeterType", {
              constructor: function(oFormatOptions, oConstraints){
                     // define the dynamic format options as the third argument
                     // 'aDynamicFormatOptionNames'
                     UnitType.apply(this, [oFormatOptions, oConstraints,
["decimals"]]);
              }
       });
});
```

In the example we defined a new `MeterType` to combine not only a number value and a unit, but the already mentioned optional dynamic format options in one single typed `PropertyBinding`.

```
<-- XML View snippet -->
<t:Table rows='energyModel>/meters'>
   ... <!-- here is more Table definition stuff, we cut this for simplicity -->

   <!-- the third part of the binding is the number of decimals for this meter
instance -->
   <m:Label text="{parts:['energyModel>value', 'energyModel>unit',
'energyModel>decimals'],type: 'sap.ui.core.samples.MeterType'}"/>

   ...
</t:Table>
```

With the new bindable dynamic format options of Unit type, you can pass the relevant meter formatting information in a generalized way through the cell's bindings.

The third argument of the base Unit type constructor is a list of dynamic format options. In our example, the binding context itself contains the information on how many-decimals should be used. Still, these dynamic format options can be bound to any value from any model.

> **i Note**
>
> If you use a combination of custom units on the Configuration and the Unit type, the format options from the type have priority.
>
> So if you define a `decimals` value for a custom unit in the Configuration, the bound values from the Unit type instance will still be taken for the formatting.

Currency Formatting

Data formatting is one of the key features in SAPUI5 and enables applications to display data according to the user locale. For this, SAPUI5 uses the Common Locale Data Repository (CLDR), a third-party library that provides locale-specific patterns. SAPUI5 uses these patterns to adapt to the conventions of different languages.

One use case for data formatting is the ability to format and parse numbers including currency information. For this specific use case, the CLDR provides patterns with preconfigured currency information such as the number of decimals for a set of different currencies. It is also possible to define custom currencies by adding new custom currencies or reconfiguring existing currencies.

Available Functions for Currency Formatting

Use the `NumberFormat.getCurrencyInstance()` factory function for creating a currency format instance. On this instance, you can call the `format` and `parse` functions.

Creating a Currency Format Instance

The `sap.ui.core.format.NumberFormat.getCurrencyInstance()` function accepts two arguments:

- The first argument, `oFormatOptions`, is a set of format options that determines the output formatting. The format option `'decimals'`, for example, defines the number of decimal digits of the formatted value. For a full list of format options, see `NumberFormat`.
- The second argument, `oLocale`, defines the locale.

The following example shows how you create a simple currency formatter instance:

```
// create a simple currency formatting instance, without any additional options
sap.ui.require(["sap/ui/core/format/NumberFormat"], function(NumberFormat) {
   var oCurrencyFormat = NumberFormat.getCurrencyInstance();
});
```

> **i Note**
>
> All code examples are based on locale English. If no locale is defined explicitly on the currency formatter instance, the locale setting of the configuration is used.

For more information, see getCurrencyInstance.

`format` Function

The currency formatter instance allows you to combine a number value with a localized currency string.

```
// "NumberFormat" required from module "sap/ui/core/format/NumberFormat"
var oCurrencyFormat = NumberFormat.getCurrencyInstance();
oCurrencyFormat.format(12345.678, "EUR"); // output: EUR 12,345.68
```

For more information, see format

`parse` Function

The `'parse'` function turns a string containing a number and a currency code (EUR, USD) or symbol (€, $) back into its raw parts: the number value and the currency code. The results are returned in an array.

```
// "NumberFormat" required from module "sap/ui/core/format/NumberFormat"
var oCurrencyFormat = NumberFormat.getCurrencyInstance();
oCurrencyFormat.parse("EUR 12,345.678"); // output: [12345.678, "EUR"]
```

For more information, see parse

Formatting Options for Currency Formatting

The following formatting options for currency formatting are available:

- `currencyCode` defines whether the code or the symbol is used when `showMeasure` is set to true.
- `trailingCurrencyCode` defines whether the currency codes are always shown after the amount, independent of the locale.

- `currencyContext` defines the pattern that is used for formatting a currency number. It can be set to standard (default) or accounting.

Let's try out these format options and create a currency formatter that is able to format currency values with symbols:

```
// "NumberFormat" required from module "sap/ui/core/format/NumberFormat"
var oCurrencyFormat = NumberFormat.getCurrencyInstance({
    currencyCode: false
});
oCurrencyFormat.format(1234.567, "USD"); // returns $1,234.57
oCurrencyFormat.format(1234.567, "JPY"); // returns ¥1,235
oCurrencyFormat.parse("$1,234.57"); // returns [1234.57, "USD"]
oCurrencyFormat.parse("¥1,235"); // returns [1235, "JPY"]
```

Custom Currencies

As mentioned above, the Common Locale Data Repository (CLDR) provides patterns with preconfigured currency information according to the locale. It is possible, however, to add new custom currencies, or to reconfigure existing currencies. These custom currencies can be configured on currency format instances, or globally in the core configuration.

Custom Currencies Configuration on Currency Format Instances

The currency `NumberFormat` instance allows you to specify custom currencies which can be used for formatting and parsing. All you have to do is to add your custom currencies as an additional format option in the `sap.ui.core.format.NumberFormat.getCurrencyInstance()` factory.

The following example shows how this is done for a specific instance:

```
// "NumberFormat" required from module "sap/ui/core/format/NumberFormat"
var oCurrencyFormat = NumberFormat.getCurrencyInstance({
    customCurrencies: {
        "Bitcoin": {
            decimals: 5
         }
     }
});
oCurrencyFormat.format(10.1234567, "Bitcoin"); // 10,12346 Bitcoin
oCurrencyFormat.parse("12 Bitcoin"); // [12, "Bitcoin"];
```

If you want to define a custom currency that falls back on the currency symbol of an already existing currency, you can configure a respective currency code (also called ISO code):

```
// "NumberFormat" required from module "sap/ui/core/format/NumberFormat"
var oCurrencyFormat = NumberFormat.getCurrencyInstance({
    currencyCode: false,
    customCurrencies: {
        "MyEuro": {
            decimals: 5,
            isoCode: "EUR"
        }
    }
});
oCurrencyFormat.format(10.1234567, "MyEuro"); // €10.12346
```

The custom currencies defined on the `NumberFormat` instance are exclusive to this instance, meaning that no other instances are affected. In addition, once you define custom currencies for an instance, only those currencies are formatted and parsed by that instance.

This also means that custom currencies defined via the configuration are not taken into account for this specific instance. This is done to circumvent ambiguities and conflicts with the CLDR currencies. So, in the above example, only Bitcoin can be formatted, but not EUR.

In the following example, the currency instance from above is used. Formatting and parsing the currency 'Bitcoin' works fine, but the instance does not know about the currency 'EUR' because of the exclusivity of the custom currencies:

```
// formatting/parsing Bitcoin is fine
oCurrencyFormat.format(9001.987654, "Bitcoin");  // 9.001,98765 Bitcoin
oCurrencyFormat.parse("12 Bitcoin"); // [12, "Bitcoin"];
// formatting/parsing EUR does not work
oCurrencyFormat.format(1.21, "EUR"); // "": results in an empty string, as the
currency is unknown
```

If you need both, CLDR predefined currencies and custom currencies, you create two separate number format instances, or use the second approach to define custom currencies as described in the next section.

Global Custom Currencies Configuration in Core Configuration

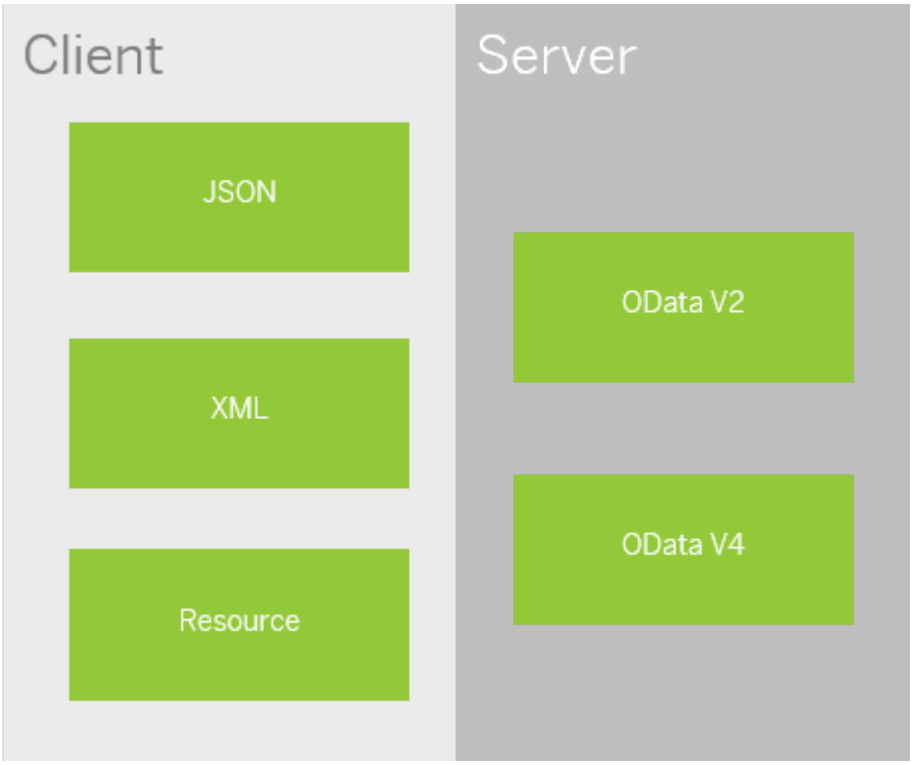
You can also add custom currencies via the formatting settings in the core configuration. Contrary to the custom currencies defined exclusively on a single currency-formatter instance, these custom currencies are available in all currency formatter instances for the current locale, except for if they also define a set of custom currencies as described in the previous section.

Adding a currency with a key which is already available in the CLDR will overwrite the CLDR currency. By this, you can overdefine single currencies, in case the CLDR provided formatting is not sufficient.

```
// "NumberFormat" required from module "sap/ui/core/format/NumberFormat"
sap.ui.getCore().getConfiguration().getFormatSettings().addCustomCurrencies({
         "MyCoin": {
            "symbol": "MC"
        },
        "Bitcoin": {
            "digits": 3
        },
        "USD": { // overwrite of an existing CLDR currency
            "digits": 5
        }
});
var oCurrencyFormat = NumberFormat.getCurrencyInstance();
// formatting a custom currency
oCurrencyFormat.format(12, "MyCoin"); // 12,00 MyCoin
// formatting an existing CLDR currency
oCurrencyFormat.format(5, "EUR"); // 5,00 EUR
// formatting an existing CLDR currency
oCurrencyFormat.format(12, "USD"); // 12,00000 USD // Default decimal setting
would have been two
```

Models

A model in the Model View Controller concept holds the data and provides methods to retrieve the data from the database and to set and update data.



- JSON Model [page 991]
- XML Model [page 993]
- Resource Model [page 995]
- OData V2 Model [page 883]
- OData V4 Model [page 918]

SAPUI5 provides the following predefined models:

- **OData model**: Enables binding of controls to data from OData services. The OData model supports two-way, one-way and one-time binding modes. However, two-way binding is currently only supported for properties, and not for aggregations.

  > **i** Note
  >
  > The OData model currently supports the following OData versions:
  >
  > - OData V2
  > - OData V4 (limited feature scope)

- **JSON model**: Can be used to bind controls to JavaScript object data, which is usually serialized in the JSON format. The JSON model is a client-side model and, therefore, intended for small data sets, which

are completely available on the client. The JSON model supports two-way (default), one-way and one-time binding modes.

- **XML model**: A client-side model intended for small data sets, which are completely available on the client. The XML model does not contain mechanisms for server-based paging or loading of deltas. The XML model supports two-way (default), one-way and one-time binding modes.
- **Resource model**: Designed to handle data in resource bundles, mainly to provide texts in different languages. The resource model only supports one-time binding mode because it deals with static texts only.

The JSON model, XML model, and the resource model are **client-side models**, meaning that the model data is loaded completely and is available on the client. Operations such as sorting and filtering are executed on the client without further server requests.

The OData (V2 or V4) model is a **server-side model** and only loads the data requested by the user interface from the server.

You can not only define one model for your applications, but define different areas in your application with different models and assign single controls to a model. You can also define nested models, for example, a JSON model defined for the application and an OData model for a table control contained in the application.

A Web application should support several data sources, such as JSON, XML, Atom, or OData. However, the way in which data binding is defined and implemented within the UI controls should be independent of the respective data source. It is also possible to create a custom model implementation for data sources that are not yet covered by the framework or are domain-specific.

Related Information

API Reference: `sap.ui.model`

OData V2 Model

The OData V2 Model enables binding of controls to data from OData services.

The OData model is a server-side model, meaning that the data set is only available on the server and the client only knows the currently visible (requested) data. Operations, such as sorting and filtering, are done on the server. The client sends a request to the server and shows the returned data.

> **i** Note
>
> Requests to the back end are triggered by list bindings (`ODataListBinding`), context bindings (`ODataContextBinding`), and CRUD functions provided by the `ODataModel`. Property bindings (`ODataPropertyBindings`) do not trigger requests.

The OData model currently supports OData version 2.0.

The following two versions of the OData model are implemented: `sap.ui.model.odata.ODataModel` and `sap.ui.model.odata.v2.ODataModel`. The `v2.ODataModel` has an improved feature set and new features will only be implemented in this model. `sap.ui.model.odata.ODataModel` is deprecated. We recommend to only use `v2.ODataModel`.

The following table shows the supported features for both OData models:

Feature	`sap.ui.model.odata.v2.ODataModel`	`sap.ui.model.odata.ODataModel`
OData version support	2.0	2.0
JSON format	Yes (default)	Yes
XML format	Yes	Yes (default)
Support of two-way binding mode	Yes; for property changes only, not yet implemented for aggregations	Experimental; only properties of one entity can be changed at the same time
Default binding mode	One-way binding	One-way binding
Client-side sorting and filtering	Yes For more information, see API Reference: sap.ui.model.odata.OperationMode.	No
$batch	Yes; all requests can be batched	Only manual batch requests are possible
Data cache in model	All data is cached in the model	Manually requested data is **not** cached
Automatic refresh	Yes (default)	Yes
Message handling	Yes, see Error, Warning, and Info Messages [page 1063]	No

> **i Note**
>
> Be aware of the Same-Origin-Policy security concept which prevents access to back ends on different domains or sites.

The requests to the service to fetch data are made automatically based on the data bindings that are defined for the controls.

Related Information

API Reference: `sap.ui.model.odata.v2.ODataModel`

Creating the Model Instance

One OData model instance can only cover one OData service. For accessing multiple services, you have to create multiple OData model instances.

The only mandatory parameter when creating an `ODataModel` instance is the service URL. It can be passed as first parameter or within the `mParameters` map to the constructor.

```
// "ODataModel" required from module "sap/ui/model/odata/v2/ODataModel"
var oModel = new ODataModel("http://services.odata.org/Northwind/
Northwind.svc/");
var oModel = new ODataModel({serviceUrl: "http://services.odata.org/Northwind/
Northwind.svc"});
```

When creating an `ODataModel` instance, a request is sent to retrieve the service metadata:

```
http://services.odata.org/Northwind/Northwind.svc/$metadata
```

Service Metadata

The service metadata is cached per service URL. Multiple OData models that are using the same service can share this metadata.

Only the first model instance triggers a `$metadata` request. A JSON representation of the service metadata can be accessed by calling the `getServiceMetadata()` method on an Odata model instance.

```
var oMetadata = oModel.getServiceMetadata();
```

> **i Note**
>
> In the `v2.ODataModel`, the service metadata is loaded asynchronously. It is not possible to load it synchronously. To get notified when the loading is finished, attach the `metadataLoaded` event.

Adding Additional URL Parameters

For OData services, you can use URL parameters for configuration. SAPUI5 sets most URL parameters automatically, according to the respective binding.

For authentication tokens or general configuration options, for example, you can add additional arguments to the request URL. Some of the parameters must not be included in every request, but should only be added to specific list or context bindings, such as `$expand` or `$select`. For this, the binding methods provide the option to pass a map of parameters, which are then included in all requests for this specific binding. The OData model currently only supports `$expand` and `$select`.

There are different ways to add URL parameters to the requests:

- Appending parameters to the service URL:

  ```
  // "ODataModel" required from module "sap/ui/model/odata/v2/ODataModel"
  ```

```
var oModel = new ODataModel("http://myserver/MyService.svc/?
myParam=value&myParam2=value");
```

These parameters will be included in every request sent to the OData server.

- Passing URL parameters with the `mparameters` map
  You can pass URL parameters that are used for `$metadata` requests only (`metadataUrlParams`) as well as URL parameters that are included only in data requests (`serviceUrlParams`). The parameters are passed as maps:

```
// "ODataModel" required from module "sap/ui/model/odata/v2/ODataModel"
var oModel = new ODataModel({
    serviceUrl: "http://services.odata.org/Northwind/Northwind.svc",
    serviceUrlParams: {
        myParam: "value1",
        myParam2: "value2"
    },
    metadataUrlParams: {
        myParam: "value1",
        myParam2: "value2"
    }
});
```

Custom HTTP Headers

You can add custom headers which are sent with each request.

To do this, provide a map of headers to the OData model constructor or use the `setHeaders()` function:

- Passing custom headers with the `mparameters` map

```
var oModel = new sap.ui.model.odata.v2.ODataModel({
    headers: {
        "myHeader1" : "value1",
        "myHeader2" : "value2"
    }
});
```

- Setting custom headers globally on a model instance

```
oModel.setHeaders({"myHeader1" : "value1", "myHeader2" : "value2"});
```

> **i Note**
>
> When you add custom headers, all previous custom headers are removed if not specified again in the headers map. Some headers are private, that is, they are set by the OData model internally and cannot be set:
>
> ```
> "accept"
> "accept-language"
> "maxdataserviceversion"
> "dataserviceversion"
> "x-csrf-token"
> ```
>
> For additional methods and parameters, see the API Reference: sap.ui.model.odata.v2.ODataModel.

Addressing Entities: Binding Path Syntax

The binding path syntax for OData models matches the URL path relative to the service URL used in OData to access specific entities or entity sets.

You access the data provided by the OData model according to the structure of the OData service as defined in the metadata of a service. URL parameters, such as filters, cannot be added to a binding path. A binding path can be absolute or relative. Absolute binding paths are resolved immediately. A relative path can only be resolved if it can be automatically converted into an absolute binding path. If, for example, a property is bound to a relative path and the parent control is then bound to an absolute path, the relative property path can be resolved to an absolute path.

The following binding samples within the `ODataModel` are taken from the Northwind demo service.

Absolute binding path (starting with a slash ('/')):

```
"/Customers"
"/Customers('ALFKI')/Address"
```

Relative binding paths that can be resolved with a context (for example `"/Customer('ALFKI')"`):

```
"CompanyName"
"Address"
"Orders"
```

Resolved to:

```
"/Customer('ALFKI')/CompanyName"
"/Customer('ALFKI')/Address"
"/Customer('ALFKI')/Orders"
```

Navigation properties, used to identify a single entity or a collection of entities:

```
"/Customers('ALFKI')/Orders"
"/Products(1)/Supplier"
```

For more information on addressing OData entries, see the URI conventions documentation on http://www.odata.org .

Accessing Data from an OData Model

The data requested from an OData service is cached in the OData model.

It can be accessed by the `getData()` and the `getProperty()` method, which returns the entity object or value. These methods do not request data from the backend, so you can only access already requested and cached entities:

```
oModel.getData("/Customer('ALFKI')");
oModel.getProperty("/Customer('ALFKI')/Address");
```

You can only access single entities and properties with these methods. To access entity sets, you can get the binding contexts of all read entities via a list binding. The values returned by these methods are copies of the data in the model, not references as in the JSONModel.

⚠ Caution

Do **not** modify objects or values inside the model manually; always use the provided API to change data in the model, or use two-way binding (see *Two-way Binding* section below).

ℹ Note

The ODataModel uses the `$skip` and `$top` URL parameters for paging. It is possible that data is modified between two paging requests, for eample, entities can be added orremoved and this may lead to data inconsistencies.

Creating Entities

To create entities for a specified entity set, call the `createEntry()` method. The method returns a context object that points to the newly created entity.

The application can bind against these objects and change the data by means of two-way binding. To store the entities in the OData backend, the application calls `submitChanges()`. To reset the changes, the application can call the `deleteCreatedEntry()` method.

The application can choose the properties that shall be included in the created object and can pass its own default values for these properties. Per default, all property values are empty, that is, undefined.

ℹ Note

The entity set and the passed properties must exist in the metadata definition of the OData service.

```
// create an entry of the Products collection with the specified properties
and values
var oContext = oModel.createEntry("/Products", { properties: { ID:99,
Name:"Product", Description:"new Product", ReleaseDate:new Date(),
Price:"10.1", Rating:1} });
// binding against this entity
oForm.setBindingContext(oContext);
// submit the changes (creates entity at the backend)
oModel.submitChanges({success: mySuccessHandler, error: myErrorHandler});
// delete the created entity
oModel.deleteCreatedEntry(oContext);
```

If created entities are submitted, the context is updated with the path returned from the creation request and the new data is imported into the model. So the context is still valid and points to the new created entity.

CRUD Operations

The OData model allows manual CRUD (create, read, update, delete) operations on the OData service. If a manual operation returns data, the data is imported into the data cache of the OData model. All operations require a mandatory `sPath` parameter as well as an optional `mParameters` map.

The `create` and `update` methods also require a mandatory `oData` parameter for passing the created or changed data object. Each operation returns an object containing a function abort, which can be used to abort

the request. If the request is aborted, the error handler is called. This ensures that the success or the error handler is executed for every request. It is also possible to pass additional header data, URL parameters, or an eTag.

- Creating entities
  The `create` function triggers a `POST` request to an OData service which was specified at creation of the OData model. The application has to specify the entity set, in which the new entity and the entity data is to be created.

```
var oData = {
    ProductId: 999,
    ProductName: "myProduct"
}
oModel.create("/Products", oData, {success: mySuccessHandler, error:
myErrorHandler});
```

- Reading entities
  The `read` function triggeres a `GET` request to a specified path. The path is retrieved from the OData service which was specified at creation of the OData model. The retrieved data is returned in the `success` callback handler function.

```
oModel.read("/Products(999)", {success: mySuccessHandler, error:
myErrorHandler});
```

- Updating entities
  The `update` function triggers a `PUT/MERGE` request to an OData service which was specified at creation of the OData model. After a successful request to update the bindings in the model, the refresh is triggered automatically.

```
var oData = {
    ProductId: 999,
    ProductName: "myProductUpdated"
}
oModel.update("/Products(999)", oData, {success: mySuccessHandler, error:
myErrorHandler});
```

- Deleting entities
  The `remove` function triggers a `DELETE` request to an OData service which was specified at creation of the OData model. The application has to specify the path to the entry which should be deleted.

```
oModel.remove("/Products(999)", {success: mySuccessHandler, error:
myErrorHandler});
```

- Refresh after change
  The model provides a mechanism to automatically refresh bindings that depend on changed entities. If you carry out a `create`, `update` or `remove` function, the model identifies the bindings and triggers a refresh for these bindings. If the model runs in batch mode, the refresh requests are bundled together with the changes in the same batch request. You can disable the auto refresh by calling `setRefreshAfterChange(false)`. If the auto refresh is disabled, the application has to take care of refreshing the respective bindings.

```
oModel.setRefreshAfterChange(false);
```

Concurrency Control and ETags

OData uses HTTP ETags for optimistic concurrency control. The service must be configured to provide them. The ETag can be passed within the parameters map for every CRUD request. If no ETag is passed, the ETag of the cached entity is used, if it is loaded already.

XSRF Token

To address cross-site request forgery, an OData service may require XSRF tokens for change requests by the client application. In this case, the client has to fetch a token from the server and send it with each change request to the server. The OData model fetches the XSRF token when reading the metadata and then automatically sends it with each write request header. If the token is no longer valid, a new token can be fetched by calling the `refreshSecurityToken` function on the OData model. The token is fetched with a request to the service root URL, which usually responds with the service document. To get a valid token, make sure that the response is **not** cached.

Refreshing the Model

The `refresh` function refreshes all data within an OData model. Each binding reloads its data from the server. For list or context bindings, a new request to the back end is triggered. If the XSRF token is no longer valid, it has to be fetched again with a `read` request to the service document. Data that has been imported via manual CRUD requests is **not** reloaded automatically.

Batch Processing

The `v2.ODataModel` supports batch processing (`$batch`) in two different ways:

- Default: All requests in a thread are collected and bundled in batch requests, meaning that request is sent in a timeout immediately after the current call stack is finished. This includes all manual CRUD requests as well as requests triggered by a binding.
- Deferred: The requests are stored and can be submitted with a manual `submitChanges()` call by the application. This also includes all manual CRUD requests as well as requests triggered by a binding.

The model cannot decide how to bundle the requests. For this, SAPUI5 provides the `groupId`. For each binding and each manual request, a `groupId` can be specified. All requests belonging to the same group are bundled into one batch request. Request without a `groupId` are bundled in the default batch group. You can use a `changeSetId` for changes. The same principle applies: Each change belonging to the same `changeSetId` is bundled into one `changeSet` in the batch request. Per default, all changes have their own `changeSet`.

You can use the `setDeferredGroups()` method to set a subset of previously defined groups to deferred.

> **i Note**
>
> The same is also valid for `setChangeGroups()` and `getChangeGroups()`.

All requests belonging to the `group` are then stored in a request queue. The deferred batch group must then be submitted manually by means of the `submitChanges()` method. If you do **not** specify a batch group ID when calling `submitChanges`, all deferred batch groups are submitted.

> **Example**
>
> Set a subset of groups to deferred:
>
> ```
> // "ODataModel" required from module "sap/ui/model/odata/v2/ODataModel"
> var oModel = new ODataModel(myServiceUrl);
> ```
>
> Pass the `groupId` to a binding:
>
> ```
> {path:"/myEntities", parameters: {groupId: "myId"}}
> ```
>
> Set the `groupId` to deferred:
>
> 1. Get the list of deferred groups:
>
>    ```
>    var aDeferredGroups = oModel.getDeferredGroups();
>    ```
> 2. Append your `groupId` to the list:
>
>    ```
>    aDeferredGroups=aDeferredGroups.concat(["myId"]);
>    ```
> 3. Set all groups to deferred:
>
>    ```
>    oModel.setDeferredGroups(aDeferredGroups);
>    ```
>
> Submit all deferred groups:
>
> ```
> oModel.submitChanges({success: mySuccessHandler, error: myErrorHandler});
> ```

Two-Way Binding

The `v2.ODataModel` enables two-way binding. Per default, all changes are collected in a batch group called "changes" which is set to deferred.

To submit the changes, use `submitChanges()`. The data changes are made on a data copy. This enables you to reset the changes without sending a new request to the backend to fetch the old data again. With `resetChanges()` you can reset all changes. You can also reset only specific entities by calling `resetChanges` with an array of entity paths.

> **i Note**
>
> Filtering and sorting is not possible if two-way changes are present as this would cause inconsistent data on the UI. Therefore, before you carry out sorting or filtering, you have to submit or reset the changes.

You can collect the changes for different entities or types in different batch groups. To configure this, use the `setChangeGroups()` method of the model:

```
// "ODataModel" required from module "sap/ui/model/odata/v2/ODataModel"
var oModel = new ODataModel(myServiceUrl);
oModel.setDeferredGroups(["myGroupId", "myGroupId2"]);
oModel.setChangeGroups({
    "EntityTypeName": {
        groupId: "myGroupId",
        [changeSetId: "ID",]
        [single: true/false,]
    }
});
oModel.submitChanges({groupId: "myGroupId", success: mySuccessHandler, error:
myErrorHandler});
```

To collect the changes for all entity types in the same batch group, use '*' as `EntityType`. If the change is not set to deferred, the changes are sent to the backend immediately. By setting the `single` parameter for `changeSet` to true or false, you define if each change results in its own change set (`true`) or if all changes are collected in one change set (`false`). The model only takes care of the `changeSetId` if `single` is set to `false`.

> **i Note**
>
> The first change of an entity defines the order in the change set.

Example

Reset changes:

```
// "ODataModel" required from module "sap/ui/model/odata/v2/ODataModel"
var oModel = new ODataModel(myServiceUrl);
//do a change
oModel.setProperty("/myEntity(0)", oValue);
//reset the change
oModel.resetChanges(["/myEntity(0)"]);
```

Binding-specific Parameters

The OData protocol specifies different URL parameters.

You can use these parameters in bindings in addition to the parameters described above:

- Expand parameter
  The `expand` parameter allows the application to read associated entities with their navigation properties:

  ```
  oControl.bindElement("/Category(1)", {expand: "Products"});
  oTable.bindRows({
      path: "/Products",
      parameters: {expand: "Category"}
  });
  ```

  In this example, all products of `"Category(1)"` are embedded inline in the server response and loaded in one request. The category for all `"Products"` is embedded inline in the response for each product.
- Select parameter

The `select` parameter allows the application to define a subset of properties that is read when requesting an entity.

```
oControl.bindElement("/Category(1)", {expand: "Products", select:
"Name,ID,Products"});
oTable.bindRows({
    path: "/Products",
    parameters: {select: "Name,Category"}
});
```

In this example, the properties `Name`, `ID` and `ofCategory(1)` as well as all properties of the embedded products are returned. The properties `Name` and `Category` are included for each product. The `Category` property contains a link to the related category entry.

- Custom query options
  You can use custom query options as input parameters for service operations. When creating the list binding, specify these custom parameter as follows:

```
oTable.bindRows({
        path: "/Products",
        parameters: {
        custom: {
            param1: "value1",
            param2: "value2"
        }
    },
    template: rowTemplate
});
```

If you use `bindElement`, you can specify custom parameters as follows:

```
oTextField.bindElement("/GetProducts", {
    custom: {
        "price" : "500"
    }
});
```

Optimizing Dependent Bindings

The ODataModel V2 supports a flag called "preliminaryContext". With this option set to true, the ODataModel is able to bundle the OData calls for dependent bindings together into fewer $batch requests.

Introduction

Two bindings are considered "dependent" if one cannot be resolved without the other being resolved first, for example a relative binding cannot be resolved without a resolved absolute binding.

If the `preliminaryContext` option is set to `false`, each binding will be resolved once its preceding binding has been resolved or if it is an absolute binding itself.

The `preliminaryContext` option can also be activated/deactivated per binding instance. This overwrites the default value set on the ODataModel instance.

Settings and Usage

ODataModel v2

The constructor parameter is named `preliminaryContext` (type Boolean) and has the following properties:

- Default value is `false`.
- It is used by the `ContextBinding` as a default value for `createPreliminaryContext` if not given in the constructor. For examples on its usage see "ContextBinding".
- It is used by the `ContextBinding` as a default value for `usePreliminaryContext` if not given in the constructor. For examples on its usage see "ContextBinding"..

ODataListBinding v2

The constructor parameter is named `usePreliminaryContext` (type Boolean) and has the following properties:

- Default value is `false`, as it is derived from the ODataModel's default.
- If set to true:
  - The `ODataListBinding` accepts preliminary contexts (for example. in a `setContext()` call).
  - The `ODataListBinding` fires a change event with `ChangeReason.Context`, if the binding is updated and a preliminary context was set.

ODataContextBinding

The `ODataContextBinding` supports two different parameters:

- `usePreliminaryContext` (same as a ODataListBinding v2)
- `createPreliminaryContext`
  - If the binding cannot be resolved, it still creates a preliminary binding context, which can be used by other subordinate dependent bindings, which have set the `usePreliminaryContext` option to `true`.
  - A change event with `ChangeReason.Context` is fired once the data is loaded for the currently preliminary `Context` instance. Afterwards, the existing `Context` instance is not considered "preliminary" anymore.

Relationship Between Binding and Model Settings

Default Behavior

To describe the preliminary context feature in more detail, we first have to look at the default Model/Binding behavior. Let's look at the simple example in the following graphic.

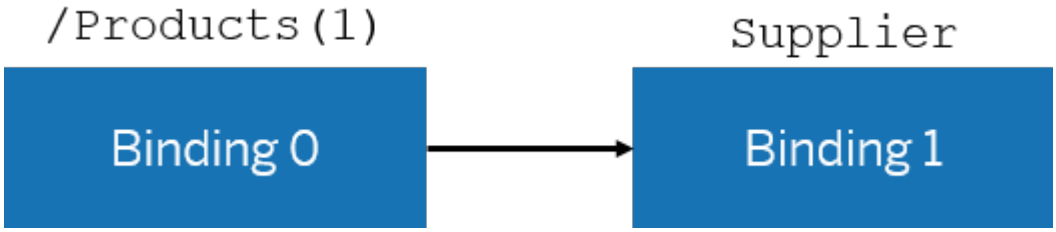


Figure 212: Simple Binding Example

Without using preliminary contexts, `Binding 1` resolves only after `Binding 0` is resolved.

For example, if `Binding 1` is a relative `ODataListBinding` on a `Table` control, its OData request will only be sent, once the data for the absolute `Binding 0` is available, for example by using an Element binding on a `Panel` control.

This leads to two subsequent OData requests, one for `Binding 0` and afterwards one for `Binding 1`, as shown in the following table:

Table 27: Simple Example: Binding Resolution

Request Number	Content
1	`GET Products(1)`
2	`GET Products(1)/Supplier`

Now let's look at a more complex example.

Figure 213: Complex Binding Example

In this example we add another binding, which will be resolved once `Binding 0` and `Binding 1` are resolved. This leads to the following three individual `$batch` requests:

Table 28: Complex Example: Binding Resolution

Request Number	Content
1	`GET Products(1)`
2	`GET Products(1)/Supplier`
3	`GET Suppliers(1)/Products`

Optimized Behavior

Let's look at the same simple example but with some optimizations.

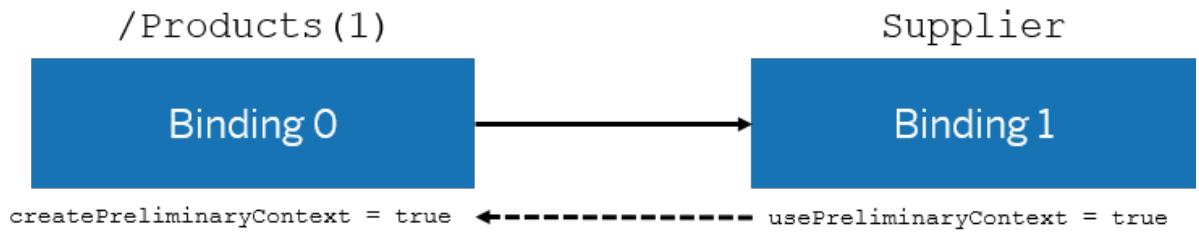

Figure 214: Simple Binding Example - Optimized

Here `Binding 1` uses the preliminary context created by `Binding 0`, and thus the request URL can directly be resolved.

This now leads to only a single `$batch` request:

Table 29: Simple Example: Binding Resolution Optimized

Request Number	Content
1	`GET Products(1)` `GET Products(1)/Supplier`

In this example `Binding 1` has set its `usePreliminaryContext` flag to `true`, and thus accepts preliminary contexts to be set.

> **i Note**
>
> If either `createPreliminaryContext` or `usePreliminaryContext` is set to `false`, the default behavior is active.

Now let's see how this works in the complex example.

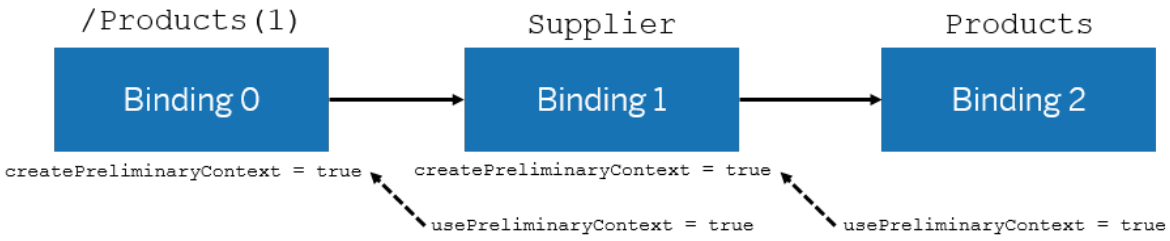

Figure 215: Complex Binding Example - Optimized

In this example we added another binding to the scenario. `Binding 2` is again a relative binding, which can only resolve once `Binding 1` is resolved. `Binding 1` behaves just as before.

In this case the single, generated request looks like this:

Table 30: Complex Example: Binding Resolution Optimized

Request Number	Content

1	`GET Products(1)`
	`GET Products(1)/Supplier`
	`GET Products(1)/Supplier/Products`

Results and Conclusion

Notice how the `Products` list of the `Supplier` is referenced through the entity `Products(1)`.This is a result of bundling all data requests into one single `$batch` request, without waiting for the `Products(1)` entity and its associated `Supplier` entity to be loaded.

As opposed to the default behavior, we do not require to have the `Products(1)` and `Supplier` entities loaded before sending the data request for the Supplier's `Products.Supplier`.So in this case we use a data path based on `Products(1)` and not the `ID` of the Supplier. You can compare that to the default behavior of the complex example described above.

Example

What would happen if one binding in the above chain does not set the `usePreliminaryContext` or the `createPreliminaryContext` option to true?

For example, if `Binding 2` sets its `usePreliminaryContext` option to `false`, the resolution chain is broken and we have a mixed scenario. Here one part is loaded optimized in one `$batch`, and the second part is loaded in a separate `$batch`:

Table 31: Complex Example: Binding Resolution Optimized

Request Number	Content
1	`GET Products(1)` `GET Products(1)/Supplier`
2	`GET Products(1)/Supplier/Products`

Note

With the `$expand` query option you can load all associated entities of another entity. In the previous examples we requested the `Product` list of a certain `Supplier` via a separate request. When using a `$expand` query instead, you could request the same information within one single request:

```
GET Products(1)?$expand=Supplier/Products
```

Even though you now also achieved to have less requests, using `$expand` has a couple of drawbacks. These can be circumvented by using the preliminary context feature, which does not have these limitations.

In OData V2, with a `$expand` you cannot use additional filters and sorters for the expanded entries. In addition, the `$expand` option always loads **ALL** associated entities, so paging with `$skip` or `$top` is also

not possible. Using the preliminary context feature, you get multiple sub-requests in a single `$batch`, yet you can easily include additional filters and sorters on the related subordinate entries.

Function Import

The `ODataModel` supports the invoking of function imports or actions by the `callFunction` method.

```
oModel.callFunction("/GetProductsByRating",{method:"GET", urlParameters:
{"rating":3}, success:fnSuccess, error: fnError})
```

If the `callFunction` request is deferred, it can be submitted via the `submitChangesmethod`.

> **i** Note
>
> Only "IN" parameters of function imports are currently supported.

Binding of Function Import Parameters

OData Model V2 supports the binding against function import parameters. This is similar to the `createEntry` method which supports binding against entity properties. The `callFunction` method returns a request handle that has a `promise`. This `promise` is resolved when the context to which it is bound is created successfully or is rejected if not:

```
var oHandle = oModel.callFunction("/GetProductsByRating", {urlParameters:
{rating:3}});
oHandle.contextCreated().then(function(oContext) {
      oView.setBindingContext(oContext);
});
```

If the function import returns result data, then the result data can be accessed and bound against in the `$result` property using the context:

```
<form:SimpleForm>
   <core:Title text="Parameters" />
   <Label text="Rating" />
   <Input value="{rating}" />
   <Button text="Submit" press=".submit" />
   <core:Title text="Result" />
   <List items="{$result}">
    <StandardListItem title="{Name}" />
   </List>
</form:SimpleForm>
```

Language

SAPUI5 uses the concept of a "current language" (see Identifying the Language Code / Locale [page 1269]). This language is automatically propagated to the OData service by the OData V2 model. For this reason,

applications must not hard code the language themselves, e.g. they must not specify the "sap-language" URL parameter as a custom query option.

Meta Model for OData V2

The implementation sap.ui.model.odata.ODataMetaModel offers a unified access to both OData Version 2.0 metadata and Version 4.0 annotations.

It uses the existing sap.ui.model.odata.ODataMetadata as a foundation and merges the OData Version 4.0 annotations from the existing sap.ui.model.odata.ODataAnnotations directly into the corresponding entity or property.

You can get an instance of sap.ui.model.odata.ODataMetaModel from an instance of sap.ui.model.odata.v2.ODataModel, see XML Templating [page 1018].

Basic Structure

The basic structure of sap.ui.model.odata.ODataMetadata is shown in the following code snippet. It shows you how the most important elements of the entity model are nested. Each of these elements (except *association set end*) can have extensions, that is, XML attribute values from some namespace. The code snippets below show how these extensions are stored and processed.

```
"dataServices": {
    "schema": [{
      "association": [{
        "end": []
      }],
      "complexType": [{
        "property": []
      }],
      "entityContainer": [{
        "associationSet": [{
          "end": []
        }],
        "entitySet": [],
        "functionImport": [{
          "parameter": []
        }]
      }],
      "entityType": [{
        "property": [],
        "navigationProperty": []
      }]
    }]
  }
}
```

The following code snippet gives a closer look and has more properties:

```
{
  "version": "1.0",
  "dataServices": {
    "dataServiceVersion": "2.0",
    "schema": [{
```

```
      "namespace": "GWSAMPLE_BASIC",
      "entityType": [{
        "name": "BusinessPartner",
        "key": {
          "propertyRef": [{
            "name": "BusinessPartnerID"
          }]
        },
        "property": [{
          "name": "BusinessPartnerID",
          "type": "Edm.String",
          "nullable": "false",
          "maxLength": "10"
        }],
        "navigationProperty": [{
          "name": "ToSalesOrders",
          "relationship": "GWSAMPLE_BASIC.Assoc_BusinessPartner_SalesOrders",
          "fromRole": "FromRole_Assoc_BusinessPartner_SalesOrders",
          "toRole": "ToRole_Assoc_BusinessPartner_SalesOrders"
        }]
      }],
      "complexType": [{
        "name": "CT_Address",
        "property": [{
          "name": "City",
          "type": "Edm.String",
          "maxLength": "40"
        }]
      }],
      "association": [{
        "name": "Assoc_BusinessPartner_SalesOrders",
        "end": [{
          "type": "GWSAMPLE_BASIC.BusinessPartner",
          "multiplicity": "1",
          "role": "FromRole_Assoc_BusinessPartner_SalesOrders"
        }, {
          "type": "GWSAMPLE_BASIC.SalesOrder",
          "multiplicity": "*",
          "role": "ToRole_Assoc_BusinessPartner_SalesOrders"
        }],
        "referentialConstraint": {
          "principal": {
            "role": "FromRole_Assoc_BusinessPartner_SalesOrders",
            "propertyRef": [{
              "name": "BusinessPartnerID"
            }]
          },
          "dependent": {
            "role": "ToRole_Assoc_BusinessPartner_SalesOrders",
            "propertyRef": [{
              "name": "CustomerID"
            }]
          }
        }
      }],
      "entityContainer": [{
        "name": "GWSAMPLE_BASIC_Entities",
        "isDefaultEntityContainer": "true",
        "entitySet": [{
          "name": "BusinessPartnerSet",
          "entityType": "GWSAMPLE_BASIC.BusinessPartner"
        }],
        "associationSet": [{
          "name": "Assoc_BusinessPartner_SalesOrders_AssocS",
          "association": "GWSAMPLE_BASIC.Assoc_BusinessPartner_SalesOrders",
          "end": [{
            "entitySet": "BusinessPartnerSet",
            "role": "FromRole_Assoc_BusinessPartner_SalesOrders"
```

```
          }, {
            "entitySet": "SalesOrderSet",
            "role": "ToRole_Assoc_BusinessPartner_SalesOrders"
          }]
        }],
        "functionImport": [{
          "name": "SalesOrder_Confirm",
          "returnType": "GWSAMPLE_BASIC.SalesOrder",
          "entitySet": "SalesOrderSet",
          "httpMethod": "POST",
          "parameter": [{
            "name": "SalesOrderID",
            "type": "Edm.String",
            "mode": "In",
            "maxLength": "10"
          }]
        }]
      }]
    }]
  }}
```

Accessing Objects and Properties

The objects in the OData meta model are arranged in arrays. `/dataServices/schema`, for example, is an array of schemas where each schema has an `entityType` property with an array of entity types, and so on. So, `/dataServices/schema/0/entityType/16` can be the path to the entity type with name "Order" in the schema with namespace "MySchema".

However, these paths are not stable: If an entity type with lower index is removed from the schema, the path to "Order" changes to `/dataServices/schema/0/entityType/15`. To avoid problems with changing indexes, `getObject` and `getProperty` support XPath-like queries for the indexes. Each index can be replaced by a query in square brackets. You can, for example, address the schema by using the path `/dataServices/schema/[${namespace}==='MySchema']` or address the entity by using the path `/dataServices/schema/[${namespace}==='MySchema']/entityType/[${name}==='Order']`.

The syntax inside the square brackets corresponds to the expression binding syntax. The query is executed for each object in the array until the result is true (truthy) for the first time. This object is then chosen. To embed such a path into an expression binding, use a complex binding syntax: `${path:'...'}`. Example: `{:= ${path:'target>extensions/[${name} === \'semantics\']/value'} === 'email'}`

Each of these queries is self-contained. The query can refer to properties of the current candidate via a relative path, for example `${name}`, but it **cannot** refer to variables such as `${meta>}` that are available in XML templating at that point.

Extensions

`extensions` array and transformed from objects into simple properties with an `sap:` prefix added to their name, see line number 8 in the following code snippet.

> **i Note**
>
> As this happens in addition, the following example shows both representations. By this, the respective annotations can be addressed via a simple relative path instead of searching an array.

```
{
  "name": "BusinessPartnerID",
  "extensions": [{
    "name": "label",
    "value": "Bus. Part. ID",
    "namespace": "http://www.sap.com/Protocols/SAPData"
  }],
  "sap:label": "Bus. Part. ID"
}
```

OData v4 Annotations

Each element of the entity model (except *association set end*) can be annotated. These annotations from the existing `sap.ui.model.odata.ODataAnnotations` are merged directly into the corresponding element. The following code snippet shows how the structure from the existing `sap.ui.model.odata.ODataMetadata`, as explained above and including extensions and constraints such as `nullable` or `maxLength`, is fleshed out with lifted v2 annotations and inlined v4 annotations, such as `Org.OData.Measures.V1.Unit` or `com.sap.vocabularies.UI.v1.Identification`. If you want to navigate the structure, for example for XML templating, it is important to understand this structure.

ODataMetaModel JSON Format:

```
"dataServices" : {
    "schema" : [{
        "namespace" : "GWSAMPLE_BASIC",
        "entityType" : [{
            "name" : "Product",
            "property" : [{
                "name" : "ProductID",
                "type" : "Edm.String",
                "nullable" : "false",
                "maxLength" : "10"
            }, {
                "name" : "SupplierName",
                "type" : "Edm.String",
                "maxLength" : "80",
                "extensions" : [{
                  "name" : "label",
                  "value" : "Company Name",
                  "namespace" : "http://www.sap.com/Protocols/SAPData"
                }, {
                  "name" : "creatable",
                  "value" : "false",
                  "namespace" : "http://www.sap.com/Protocols/SAPData"
                }, {
                  "name" : "updatable",
                  "value" : "false",
                  "namespace" : "http://www.sap.com/Protocols/SAPData"
                }],
                "sap:label" : "Company Name",
                "sap:creatable" : "false",
                "sap:updatable" : "false"
                "Org.OData.Core.V1.Computed" : {
```

```
                    "Bool" : "true"
                }
            }, {
                "name" : "WeightMeasure",
                "type" : "Edm.Decimal",
                "precision" : "13",
                "scale" : "3",
                "Org.OData.Measures.V1.Unit" : {
                    "Path" : "WeightUnit"
                }
            }, {
                "name" : "WeightUnit",
                "type" : "Edm.String",
                "maxLength" : "3"
            }],
            "com.sap.vocabularies.UI.v1.DataPoint" : {
                "Value" : {
                    "Path" : "WeightMeasure",
                    "EdmType" : "Edm.Decimal"
                }
            },
            "com.sap.vocabularies.UI.v1.Identification" : [{
                "Value" : {"Path" : "ProductID"}
            }, {
                "Value" : {"Path" : "SupplierName"}
            }, {
                "Value" : {"Path" : "WeightMeasure"}
            }]
        }]
    }]
}
```

Enhancement of the OData Meta Model

In addition to the easy access to the SAP-specific OData annotations, such as `sap:label`, corresponding vocabulary-based annotations are mixed in if they are not yet defined in the OData Version 4.0 annotations of the existing `sap.ui.model.odata.ODataAnnotations`.

> **i Note**
>
> Annotation terms are not merged, but replaced as a whole ("PUT" semantics). If the same annotation term with the same target is also contained in an annotation file, the complete OData V4 annotation converted from the OData V2 annotation is replaced by the one contained in the annotation file for the specified target. Converted annotations never use a qualifier and are only overwritten by the same annotation term without a qualifier.

The following tables show the transformations that are implemented with version 1.30 of SAPUI5 (variatons of this are marked accordingly). In the examples shown below, `AnyPath` is a path expression as defined in the OData Version 4.0 specification , section 14.5.12.

Transformations defined at `EntitySet`:

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:creatable = "false"`	`"Org.OData.Capabilities.V1.InsertRestrictions": { "Insertable" : { "Bool" : "false" } }`
`sap:deletable = "false"`	`"Org.OData.Capabilities.V1.DeleteRestrictions": { "Deletable" : { "Bool" : "false" } }` **i Note** If both, `sap:deletable` and `sap:deletable-path` are given, the service is broken and it is handled as `sap:deletable="false"`.
`sap:deletable-path = "AnyPath"` Where `AnyPath` is a path expression that identifies a Boolean property in the context of the entity type of the entity set. The value of this property indicates whether the entity can be deleted or not.	`"Org.OData.Capabilities.V1.DeleteRestrictions": { "Deletable" : { "Path" : "AnyPath" } }` **i Note** If both, `sap:deletable` and `sap:deletable-path` are given, the service is broken and it is handled as `sap:deletable="false"`.
`sap:label = "foo"` Where `foo` is any text.	`"com.sap.vocabularies.Common.v1.Label" : {"String" : "foo" }`
`sap:pageable = "false"`	`"Org.OData.Capabilities.V1.SkipSupported": {"Bool" : "false" }, "Org.OData.Capabilities.V1.TopSupported": {"Bool" : "false" }`
`sap:requires-filter = "true"`	`"Org.OData.Capabilities.V1.FilterRestrictions": { "RequiresFilter" : { "Bool" : "true" } }`
`sap:searchable = "false"` Alternatively, do not use the `sap:searchable` annotation.	`"Org.OData.Capabilities.V1.SearchRestrictions": { "Searchable" : { "Bool" : "false" } }`
`sap:topable = "false"`	`"Org.OData.Capabilities.V1.TopSupported": {"Bool" : "false" }`

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:updatable = "false"`	`"Org.OData.Capabilities.V1.UpdateRestrictions": { "Updatable" : { "Bool" : "false" } }` **Note** If both, `sap:updatable` and `sap:updatable-path` are given, the service is broken and it is handled as `sap:updatable="false"`.
`sap:updatable-path = "AnyPath"` Where `AnyPath` is a path expression that identifies a Boolean property in the context of the entity type of the entity set. The value of this property indicates whether the entity can be updated or not.	`"Org.OData.Capabilities.V1.UpdateRestrictions": { "Updatable" : { "Path" : "AnyPath" } }` **Note** If both, `sap:updatable` and `sap:updatable-path` are given, the service is broken and it is handled as `sap:updatable="false"`.

Transformations defined at `Property`:

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:label = "foo"` Where `foo` is any text.	`"com.sap.vocabularies.Common.v1.Label" : {"String" : "foo" }` **Note** The resulting annotation is added at different places, not to the `Property`.

`sap:creatable = "true"`
 	
and
 	
`sap:updatable = "false"`
	`"Org.OData.Core.V1.Immutable": { "Bool" : "true" }`

`sap:creatable = "false"`
 	
and
 	
`sap:updatable = "false"`
	`"Org.OData.Core.V1.Computed": { "Bool" : "true"}`

`sap:display-format = "NonNegative"`	`"com.sap.vocabularies.Common.v1.IsDigitSequence": { "Bool" : "true" }`

OData V2 SAP Extension	Resulting OData V4 Annotation
i Note `NonNegative` indicates that only non-negative numeric values are provided and persisted, other input leads to errors; intended for `Edm.String` fields that are internally stored as `NUMC`.	
`sap:display-format = "UpperCase"`	`"com.sap.vocabularies.Common.v1.IsUpperCase": { "Bool" : "true" }`
`sap:field-control = "AnyPath"` Where `AnyPath` is a path expression that identifies a property containing a numeric value that controls visibility..	`"com.sap.vocabularies.Common.v1.FieldControl": { "Path" : "AnyPath" }`
`sap:filterable = "false"`	`"Org.OData.Capabilities.V1.FilterRestrictions": { "NonFilterableProperties" : [ { "PropertyPath" : "PropA " }, { "PropertyPath" : "PropC " }] }` For example, if `sap:filterable` is set to `false` for properties `PropA` and `PropC`. **i Note** The resulting annotation is added to the `EntitySet`, not to the `Property`.
`sap:filter-restriction="multi-value"` For example, at a `BusinessPartnerID` property of a `BusinessPartner` type.	`"com.sap.vocabularies.Common.v1.FilterExpressionRestrictions": [{ "Property" : { "PropertyPath" : "BusinessPartnerID" }, "AllowedExpressions" : { "EnumMember": "com.sap.vocabularies.Common.v1.FilterExpressionType/MultiValue" } }]` At the corresponding entity set, for example, `BusinessPartnerSet.multi-value` is mapped to `MultiValue`, `single-value` is mapped to `SingleValue`, and `interval` is mapped to `SingleInterval`. **i Note** The resulting annotation is added to the `EntitySet`, not to the `Property`.

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:heading = "foo"` Where `foo` is any text.	`"com.sap.vocabularies.Common.v1.Heading": { "String" : "foo" }`
`sap:precision = "AnyPath"` Where `AnyPath` is a path expression that identifies a property in the context of the entity type containing the number of significant decimal places for a numeric value.	`"Org.OData.Measures.V1.Scale": { "Path" : "AnyPath" }`
`sap:quickinfo = "foo"` Where `foo` is any text.	`"com.sap.vocabularies.Common.v1.QuickInfo": { "String" : "foo" }`
`sap:required-in-filter = "true"`	If `sap:required-in-filter` is set to `TRUE` for the `PropA` and `PropC` properties: `"Org.OData.Capabilities.V1.FilterRestrictions": { "RequiredProperties" : [ { "PropertyPath" : "PropA " }, { "PropertyPath" : "PropC " }] }` **i Note** The resulting annotation is added to the `EntitySet`, not to the `Property`.
`sap:sortable = "false"`	If `sap:sortable` is set to `FALSE` for the `PropA` and `PropC` properties: `"Org.OData.Capabilities.V1.SortRestrictions": { "NonSortableProperties" : [ { "PropertyPath" : "PropA " }, { "PropertyPath" : "PropC " }]}` **i Note** The resulting annotation is added to the `EntitySet`, not to the `Property`.
`sap:text = "AnyPath"` Where `AnyPath` is a path expression that identifies a property in the context of the entity type containing a human-readable text for the value of this property.	`"com.sap.vocabularies.Common.v1.Text": { "Path" : "AnyPath" }`

OData V2 SAP Extension	Resulting OData V4 Annotation

`sap:unit="WeightUnit"`
 	
or
 	
`sap:unit="CurrencyCode"`
 	
Where `WeightUnit` and `CurrencyCode` are names of properties in the same entity and `WeightUnit` points to a property with `sap-semantics:unit-of-measure` and `CurrencyCode`points to a property with `sap-semantics:currency-code`.
	`"Org.OData.Measures.V1.Unit": { "Path" : "WeightUnit" }`
	
	or
	
	`"Org.OData.Measures.V1.ISOCurrency": { "Path" : "CurrencyCode" }`

`sap:visible="false"`	`"com.sap.vocabularies.UI.v1.Hidden" : { "Bool" : "true" }`
	
	Deprecated as of SAPUI5 1.44:
	
	`"com.sap.vocabularies.Common.v1.FieldControl": { "EnumMember" : "com.sap.vocabularies.Common.v1.FieldControlType/Hidden" }`

`sap:aggregation-role="dimension"`	`"com.sap.vocabularies.Analytics.v1.Dimension" : { "Bool" : "true" }` **i Note** Implemented with version 1.46.
`sap:aggregation-role="measure"`	`"com.sap.vocabularies.Analytics.v1.Measure" : { "Bool" : "true" }` **i Note** Implemented with version 1.46.
`sap:semantics="year"`	`"com.sap.vocabularies.Common.v1.IsCalendarYear" : {"Bool" : "true"}` **i Note** Implemented with version 1.50.
`sap:semantics="yearmonth"`	`"com.sap.vocabularies.Common.v1.IsCalendarYearMonth" : {"Bool" : "true"}`

OData V2 SAP Extension	Resulting OData V4 Annotation
	i Note Implemented with version 1.50.
`sap:semantics="yearmonthday"`	`"com.sap.vocabularies.Common.v1.IsCalendarDate" : {"Bool" : "true"}` **i Note** Implemented with version 1.50.
`sap:semantics = url`	`"Org.OData.Core.V1.IsURL" : { "Bool" : "true" }` **i Note** Implemented with version 1.52.
`sap:semantics="yearquarter"`	`"com.sap.vocabularies.Common.v1.IsCalendarYearQuarter" : {"Bool" : "true"}` **i Note** Implemented with version 1.54.
`sap:semantics="yearweek"`	`"com.sap.vocabularies.Common.v1.IsCalendarYearWeek" : {"Bool" : "true"}` **i Note** Implemented with version 1.54.
`sap:semantics="fiscalyear"`	`"com.sap.vocabularies.Common.v1.IsFiscalYear" : {"Bool" : "true"}` **i Note** Implemented with version 1.54.
`sap:semantics="fiscalyearperiod"`	`"com.sap.vocabularies.Common.v1.IsFiscalYearPeriod" : {"Bool" : "true"}` **i Note** Implemented with version 1.54.

Transformations defined at `NavigationProperty`:

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:filterable = "false"`	`"Org.OData.Capabilities.V1.FilterRestrictions": { "NonFilterableProperties" : [ { "PropertyPath" : "PropA " }, { "PropertyPath" : "PropC " } ] }` For example, if `sap:filterable` is set to `false` for properties `PropA` and `PropC` **i Note** The resulting annotation is added to the `EntitySet`, **not** to the `NavigationProperty`. **i Note** Implemented with version 1.42. **⚠ Caution** Deprecated with version 1.54. See entry below.
`sap:filterable = "false"`	`"Org.OData.Capabilities.V1.NavigationRestrictions": { "RestrictedProperties": [{ "FilterRestrictions": {"Filterable": false}, "NavigationProperty": {"NavigationPropertyPath": "NavPropA"} }, { "FilterRestrictions": {"Filterable": false}, "NavigationProperty": {"NavigationPropertyPath": "NavPropB"} }] }`  For example, if `sap:filterable` is set to false for navigation properties `NavPropA` and `NavPropB`.  **i Note** The resulting annotation is added to the `EntitySet`, **not** to the `NavigationProperty`.

OData V2 SAP Extension	Resulting OData V4 Annotation
	i Note Implemented with version 1.54.

`sap:creatable = "false"`	`"Org.OData.Capabilities.V1.InsertRestrictions": {`
	
	`"NonInsertableNavigationProperties" : [`
	`{ "NavigationPropertyPath" : "NavPropA " },`
	`{ "NavigationPropertyPath" : "NavPropC " }`
	`]`
	`}`
	
	For example, if `sap:creatable` is set to `false` for navigation properties `NavPropA` and `NavPropC`
	
	i Note
	The resulting annotation is added to the `EntitySet`, **not** to the `NavigationProperty`.
	
	i Note
	If `sap:creatable` and `sap:creatable-path` are given, the service is broken and it is handled as `sap:creatable="false"`.
	
	i Note
	Implemented with version 1.42.

`sap:creatable-path="Creatable"`	`"Org.OData.Capabilities.V1.InsertRestrictions": {`
	
	`"NonInsertableNavigationProperties" : [{`
	`"IF" : [{`
	`"Not" : {`
	`"Path" : "Creatable"`
	`}`
	`}, {`
	
	`"NavigationPropertyPath" : "NavPropA"`
	`}]`
	`}]`
	`}`

OData V2 SAP Extension	Resulting OData V4 Annotation
	Note The resulting annotation is added to the `EntitySet`, **not** to the `NavigationProperty`. **Note** If `sap:creatable` and `sap:creatable-path` are given, the service is broken and it is handled as `sap:creatable="false"`. **Note** Implemented with version 1.42.

Transformations defined at `Schema`:

OData V2 SAP Extension	Resulting OData V4 Annotation
`schema-version="foo"`	`"@Org.Odata.Core.V1.SchemaVersion" : "foo"` **Note** Implemented with version 1.54.

Depending on the value of the `sap:semantics` annotation, different vocabulary-based annotations are generated. The following transformations are implemented and defined at `property`. In the examples of the resulting JSON at the "defined at" object, `PROPERTY` is a placeholder for the name of the property at which the `sap:semantics` annotation is defined.

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:semantics = "currency-code"`	see `sap:unit` above
`sap:semantics = "unit-of-measure"`	see `sap:unit` above
`sap:semantics = "name"`	`"com.sap.vocabularies.Communication.v1.Contact" : { "fn" : { "Path" : "PROPERTY" } }`
`sap:semantics = "givenname"`	`"com.sap.vocabularies.Communication.v1.Contact" : { "n" : { "given" : { "Path" : "PROPERTY" } } }`

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:semantics = "middlename"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "n" : { "additional" : { "Path" : "PROPERTY" } } }`
`sap:semantics = "familyname"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "n" : { "surname" : { "Path" : "PROPERTY" } } }`
`sap:semantics = "nickname"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "nickname" : { "Path" : "PROPERTY" } }`
`sap:semantics = "honorific"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "n" : { "prefix" : { "Path" : "PROPERTY" } } }`
`sap:semantics = "suffix"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "n" : { "suffix" : { "Path" : "PROPERTY" } } }`
`sap:semantics = "note"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "note" : { "Path" : "PROPERTY" } }`
`sap:semantics = "photo"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "photo" : { "Path" : "PROPERTY" } }`
`sap:semantics = "city"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "adr" : { "locality" : { "Path" : "PROPERTY" } } }`
`sap:semantics = "street"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "adr" : { "street" : { "Path" : "PROPERTY" } } }`
`sap:semantics = "country"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "adr" : { "country" : { "Path" : "PROPERTY" } } }`
`sap:semantics = "region"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "adr" : { "region" : { "Path" : "PROPERTY" } } }`

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:semantics = "zip"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "adr" : { "code" : { "Path" : "PROPERTY" } } }`
`sap:semantics = "pobox"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "adr" : { "pobox" : { "Path" : "PROPERTY" } } }`
`sap:semantics = "org"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "org" : { "Path" : "PROPERTY" } }`
`sap:semantics = "org-unit"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "orgunit" : { "Path" : "PROPERTY" } }`
`sap:semantics = "org-role"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "role" : { "Path" : "PROPERTY" } }`
`sap:semantics = "title"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "title" : { "Path" : "PROPERTY" } }`
`sap:semantics = "bday"`	`"com.sap.vocabularies.Communication.v1 .Contact" : { "bday" : { "Path" : "PROPERTY" } }`
`sap:semantics = "dtstart"`	`"com.sap.vocabularies.Communication.v1 .Event" : { "dtstart" : { "Path" : "PROPERTY" } }`
`sap:semantics = "dtend"`	`"com.sap.vocabularies.Communication.v1 .Event" : { "dtend" : { "Path" : "PROPERTY" } }`
`sap:semantics = "duration"`	`"com.sap.vocabularies.Communication.v1 .Event" : { "duration" : { "Path" : "PROPERTY" } }`
`sap:semantics = "class"`	`"com.sap.vocabularies.Communication.v1 .Event" : { "class" : { "Path" : "PROPERTY" } }`

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:semantics = "status"`	`"com.sap.vocabularies.Communication.v1 .Event" : { "status" : { "Path" : "PROPERTY" } }`
`sap:semantics = "transp"`	`"com.sap.vocabularies.Communication.v1 .Event" : { "transp" : { "Path" : "PROPERTY" } }`
`sap:semantics = "fbtype"`	`"com.sap.vocabularies.Communication.v1 .Event" : { "fbtype" : { "Path" : "PROPERTY" } }`
`sap:semantics = "wholeday"`	`"com.sap.vocabularies.Communication.v1 .Event" : { "wholeday" : { "Path" : "PROPERTY" } }`
`sap:semantics = "location"`	`"com.sap.vocabularies.Communication.v1 .Event" : { "location" : { "Path" : "PROPERTY" } }`
`sap:semantics = "due"`	`"com.sap.vocabularies.Communication.v1 .Task" : { "due" : { "Path" : "PROPERTY" } }`
`sap:semantics = "completed"`	`"com.sap.vocabularies.Communication.v1 .Task" : { "completed" : { "Path" : "PROPERTY" } }`
`sap:semantics = "percent-complete"`	`"com.sap.vocabularies.Communication.v1 .Task" : { "percentcomplete" : { "Path" : "PROPERTY" } }`
`sap:semantics = "priority"`	`"com.sap.vocabularies.Communication.v1 .Task" : { "priority" : { "Path" : "PROPERTY" } }`
`sap:semantics = "from"`	`"com.sap.vocabularies.Communication.v1 .Message" : { "from" : { "Path" : "PROPERTY" } }`
`sap:semantics = "sender"`	`"com.sap.vocabularies.Communication.v1 .Message" : { "sender" : { "Path" : "PROPERTY" } }`

OData V2 SAP Extension	Resulting OData V4 Annotation
`sap:semantics = "subject"`	`"com.sap.vocabularies.Communication.v1 .Message" : { "subject" : { "Path" : "PROPERTY" } }`
`sap:semantics = "body"`	`"com.sap.vocabularies.Communication.v1 .Message" : { "body" : { "Path" : "PROPERTY" } }`
`sap:semantics = "received"`	`"com.sap.vocabularies.Communication.v1 .Message" : { "received" : { "Path" : "PROPERTY" } }`

`sap:semantics = "tel"`	At the `EntityType` or `ComplexType`:
	`"com.sap.vocabularies.Communication.v1 .Contact" : { "tel" : [{ "uri" : { "Path" : "ATTRIBUTE" } }]}`
	Where `ATTRIBUTE` is the name of the annotated attribute of an `EntityType` or `ComplexType`.
	At `Property`:
	`"com.sap.vocabularies.Communication.v1 .IsPhoneNumber" : { "Bool" : "true" }`

`sap:semantics = "tel";type=cell,work`	At the `EntityType` or `ComplexType`:
	`"com.sap.vocabularies.Communication.v1 .Contact" : { "tel" : [{ "type" : { "EnumMember": "com.sap.vocabularies.Communication.v1 .PhoneType/cell" + " com.sap.vocabularies.Communication.v1. PhoneType/work" }, "uri" : { "Path" : "ATTRIBUTE" } }]}`
	Where `ATTRIBUTE` is the name of the annotated attribute of an `EntityType` or `ComplexType`.
	At `Property`:
	`"com.sap.vocabularies.Communication.v1 .IsPhoneNumber" : { "Bool" : "true" }`

OData V2 SAP Extension	Resulting OData V4 Annotation

`sap:semantics = "email"`	At the `EntityType` or `ComplexType`:
	`"com.sap.vocabularies.Communication.v1 .Contact" : { "address" : [{ "uri" : { "Path" : "ATTRIBUTE" } }]}`
	Where `ATTRIBUTE` is the name of the annotated attribute of an `EntityType` or `ComplexType`.
	At `Property`:
	`"com.sap.vocabularies.Communication.v1 .IsEmailAddress" : { "Bool" : "true" }`

`sap:semantics = "email";type=work,pref`	At the `EntityType` or `ComplexType`:
	`"com.sap.vocabularies.Communication.v1 .Contact" : { "email" : [{ "address" : { "Path" : "ATTRIBUTE" }, "type" : { "EnumMember" : "com.sap.vocabularies.Communication.v1 .ContactInformationType/work" + "com.sap.vocabularies.Communication.v1 .ContactInformationType/preferred" } }]}`
	Where `ATTRIBUTE` is the name of the annotated attribute of an `EntityType` or `ComplexType`.
	At `Property`:
	`"com.sap.vocabularies.Communication.v1 .IsEmailAddress" : { "Bool" : "true" }`

OData V2 Model [page 883]
Class `sap.ui.model.odata.ODataMetaModel`

OData V4 Model

The `sap.ui.model.odata.v4.ODataModel` is the model implementation for consuming an OData V4 service.

> **! Restriction**
>
> Due to the limited feature scope of this version of the SAPUI5 OData V4 model, check that all required features are in place before developing freestyle and Fiori elements applications. Double check the detailed documentation of the features, as certain parts of a feature may be missing. While we aim to be compatible with existing controls, some controls might not work due to small incompatibilities compared to `sap.ui.model.odata.(v2.)ODataModel`, or due to missing features in the model (such as tree binding). This also applies to smart controls (`sap.ui.comp` library) that do not support the SAPUI5 OData V4 model, as well as controls such as `TreeTable` and `AnalyticalTable`, which are not supported together with the SAPUI5 OData V4 model. The interface for applications has been changed for easier and more efficient use of the model. For a summary of these changes, see Changes Compared to OData V2 Model [page 971].

The OData V4 model supports the following:

- Read access
- Updating properties of OData entities (in entity sets and contained entities) via two-way-binding
- Deleting entities
- Operation (function and action) execution
- Grouping data requests in a batch request
- Server-side sorting and filtering

> **i Note**
>
> The OData V4 model documentation contains several code samples. These refer to the Sales Orders sample in the Demo Kit.

Changes Compared to OData V2 Model [page 971]
sap.ui.model.odata.v4.ODataModel
Sample: Sales Orders

Model Instantiation and Data Access

One OData V4 model instance can only cover one OData service. This section describes the creation of a model instance in more detail.

The OData V4 model is primarily designed for OData V4 services. Nevertheless, OData V2 services may be used through an adapter as well. For more information see: Consuming OData V2 Services with the OData V4 Model [page 977]

When creating an OData V4 model instance, the only parameter you actually need is a map. This map must contain at least the properties `serviceUrl` and `synchronizationMode`. For more information, see the sap.ui.model.odata.v4.ODataModel constructor API documentation in the Demo Kit.

OData V4 model instantiation:

```
sap.ui.define(["sap/ui/model/odata/v4/ODataModel"], function (ODataModel) {
    var oModel = new ODataModel({
        serviceUrl : "/sap/opu/odata4/IWBEP/V4_SAMPLE/default/IWBEP/
V4_GW_SAMPLE_BASIC/0001/",
        synchronizationMode : "None"
    });
});
```

OData Custom Query Options

An OData service accepts query options placed in the service URL query part, as explained on the URL conventions page OData Version 4.0 Part 2: URL Conventions in chapter 2 *URL Components*. The OData V4 model accepts OData custom query options only as explained in section 5.2 *Custom Query Options* of the URL conventions page; you must not provide OData system query options (starting with "$") or OData parameter aliases (starting with "@") at model level, see sections 5.1 *System Query Options* and 5.3 *Parameter Aliases* in the URL conventions page.

> **i** Note
>
> Note that it's possible to specify certain system query options for OData V4 model bindings. For more information, see Bindings [page 922].

OData V4 model instantiation with service URL parameters:

```
sap.ui.define(["sap/ui/model/odata/v4/ODataModel"], function (ODataModel) {
    var oModel = new ODataModel({
        serviceUrl : "/sap/opu/odata4/IWBEP/V4_SAMPLE/default/IWBEP/
V4_GW_SAMPLE_BASIC/0001/?customParam=foo",
        synchronizationMode : "None"
    });
});
```

Default Groups for Batch Control

The OData V4 model allows you to specify whether or not requests are bundled and sent as a batch request, and when the requests are sent. For more information, see Batch Control [page 952].

The parameter `groupId` specifies the default batch group and defaults to `"$auto"`. You can use the parameter `updateGroupId` to set a batch group for update requests only. If you do not set this parameter, the `groupId` will be used.

The following code instantiates a model that bundles all update requests in the batch group `"myAppUpdateGroup"`; the batch request can then be sent using `oModel.submitBatch("myAppUpdateGroup")`.

OData V4 model with `updateGroupId`:

```
sap.ui.define(["sap/ui/model/odata/v4/ODataModel"], function (ODataModel) {
    var oModel = new ODataModel({
        serviceUrl : "/sap/opu/odata4/IWBEP/V4_SAMPLE/default/IWBEP/
V4_GW_SAMPLE_BASIC/0001/",
        synchronizationMode : "None",
        updateGroupId : "myAppUpdateGroup"
    });
});
```

Instantiating an OData V4 Model Using the Descriptor File (`manifest.json`)

The code sample below shows the parts of a Descriptor for Applications, Components, and Libraries [page 734] (`manifest.json`) that are relevant for instantiating an OData V4 model:

```
{
    "sap.app" : {
        "dataSources" : {
            "default" : {
                "uri" : "/sap/opu/odata4/IWBEP/V4_SAMPLE/default/IWBEP/
V4_GW_SAMPLE_BASIC/0001/",
                "type" : "OData",
                "settings" : {
                    "odataVersion" : "4.0"
                }
            }
        }
    },
    "sap.ui5" : {
        "models" : {
            "" : {
                "dataSource" : "default",
                "settings" : {
                    "synchronizationMode" : "None",
                    "updateGroupId" : "myAppUpdateGroup"
                }
            }
        }
    }
}
```

Data Access

The OData V4 model only supports data access using bindings. It does not provide any direct access to the data. For more information, see Unsupported Superclass Methods and Events [page 969]. One exception is sap.ui.model.odata.v4.Context#setProperty. It allows to update a property without using a property binding, even without reading the data first.

Language

SAPUI5 uses the concept of a "current language" (see Identifying the Language Code / Locale [page 1269]). This language is automatically propagated to the OData service by the OData V4 model. For this reason, applications must not hard code the language themselves, e.g. they must not specify the `"sap-language"` URL parameter as a custom query option.

Set HTTP Header Fields

You can set headers for HTTP requests sent by the OData V4 model: This is possible statically by adding them to the `manifest.json`, or dynamically with the method ODataModel#changeHttpHeaders. These headers are applied to data and metadata requests sent by the model. The `ODataModel` propagates its HTTP headers to value list models created via ODataMetaModel#createValueListInfo; when changing HTTP headers for the model, however, these changes are not applied to existing value list models: If value list models require the new headers, you have to additionally call `ODataModel#changeHttpHeaders` for each of them. For details, see ODataModel#changeHttpHeaders.

Sample: Set HTTP header `custom` in manifest.json:

```
{
    "sap.app" : {
        "dataSources" : {
            "default" : {
                "uri" : "/sap/opu/odata4/IWBEP/V4_SAMPLE/default/IWBEP/
V4_GW_SAMPLE_BASIC/0001/",
                "type" : "OData",
                "settings" : {
                    "odataVersion" : "4.0"
                }
            }
        }
    },
    "sap.ui5" : {
        "models" : {
            "" : {
                "dataSource" : "default",
                "settings" : {
                    "autoExpandSelect" : true,
                    "httpHeaders" : {
                        "custom" : "foo"
                    },
                    "synchronizationMode" : "None",

                }
            }
        }
    }
}
```

Bindings

Bindings connect SAPUI5 view elements to model data, allowing changes in the model to be reflected in the view element and vice versa.

The OData V4 model supports the following types of binding:

- **List bindings**, which represent a collection (of OData entities, complex or primitive types) such as `/SalesOrderList` (see the sap.ui.model.odata.v4.ODataListBinding API documentation in the Demo Kit)
- **Context bindings**, which represent a single entity such as `/SalesOrderList('0500000000')` or a structural property with complex type (see the sap.ui.model.odata.v4.ODataContextBinding API documentation in the Demo Kit)
- **Property bindings**, which represent a single, primitive type property in an entity or complex type such as `/ProductList('HT-1000')/Name` (see the sap.ui.model.odata.v4.ODataPropertyBinding API documentation in the Demo Kit)

Creating Bindings

The OData V4 model offers the factory methods `bindList`, `bindContext` and `bindProperty` for creating bindings. Typically, these methods are not called directly in applications, but indirectly by the following:

- Binding an SAPUI5 control through an API such as `oForm.bindElement("{/SalesOrderList('0500000000')}");`
  This sample binds a form to a certain sales order so that form elements can be bound to display or change single properties of the sales order.

  > **i Note**
  >
  > Note that binding expressions can be complex so that they can take additional properties to specify the binding further in addition to the path:
  >
  > ```
  > oForm.bindElement({path : "/SalesOrderList('0500000000')", parameters :
  > {$expand : "SO_2_SOITEM", ...}, events : {dataReceived :
  > '.onDataEvents', ...}});
  > ```
  >
  > This allows you, for instance, to specify OData V4 binding parameters [page 928] such as `$expand` or attach to OData V4 Binding Events [page 938] such as `dataReceived`.

  For a complete example, see the `onSalesOrderSelect` method (file: `Main.controller.js`) in the SalesOrders sample in the Demo Kit.
- Declaring a binding for a control property in an XML view such as the following:

  ```
  <Table items="{path : '/SalesOrderList', parameters : { $expand : 'SO_2_BP',
  $filter : 'BuyerName ge \'M\'', ...}, events : {dataReceived :
  '.onDataEvents', ... } }">
  ```

  For a complete example, see the `Main.view.xml` file in the SalesOrders sample in the Demo Kit.

Path Syntax

According to the specification available under OData Version 4.0 Part 2: URL Conventions, 4 Resource Path, every resource path (relative to the service root URL, no query options) is a valid data binding path within this model if a leading slash is added. For example, you can use `"/EMPLOYEES('A%2FB%26C')"` to access an entity instance with key "A/B&C". Note that appropriate URI encoding is necessary.

Furthermore, the OData V4 model only supports OData SimpleIdentifier with characters from the US ASCII code character set.

Initialization and Read Requests

Bindings are called **absolute** if their path starts with a forward slash "/"; otherwise they are called **relative**. Relative bindings are initial meaning that they have no data as long as they have no context. They obtain a context either from a list binding where the context represents an entity for a certain index in an entity collection or from a context binding where the context represents the one entity of the context binding. The binding which created the context is called the **parent binding** of the relative binding; the relative binding is a **child binding** of its parent binding. Dependent bindings of a binding are the set of child bindings of the binding itself and the dependent bindings of its children. If the binding has no child bindings, it is the empty set.

An absolute binding creates a data service request to read data once data is requested by a bound control or a child control with a relative binding. The read URL path is the model's service URL concatenated with the binding's path. The read URL query options are the union of the binding's and model query options; query options specified for the binding overwrite model query options.

A relative list or context binding creates a data service request once it has a context in the following cases:

- The relative binding has parameters, such as OData query options like `$select`, or binding-specific parameters with a name starting with `$$` see the *Parameters* subsection below. If you want a relative binding to create its own data service request, use the binding-specific parameter `$$ownRequest`.
- You specify a dynamic filter or dynamic sorter for a list binding and use `sap.ui.model.odata.OperationMode.Server`, see sections Filtering [page 939] and Sorting [page 942].

> **i Note**
>
> If the model is configured to compute `$expand` and `$select` automatically, this behaviour changes, see Automatic determination of $expand and $select [page 937].

> **i Note**
>
> A relative property binding never creates a data service request; its binding parameters are ignored in this case.

In all other cases, a relative binding reads data from its parent binding that created the context. In case of an own data service request, the read URL path is the model's service URL concatenated with the path of the binding's context and the binding's path. Set the binding-specific parameter `$$canonicalPath` to `true` to use the canonical path computed from the context's path instead of the context's path in the read URL.

The point in time that is used to actually send the request is determined as explained in the section Batch Control [page 952]. Bindings which create own data service requests cache data from data service responses. They do not send a data service request if data can be served from this cache.

> **i Note**
>
> List bindings read data in pages, i.e. they only access a certain index range from their bound collection; they only trigger a new data service request if indexes are accessed which have not yet been read.

You can delete the cache for an absolute binding using its `refresh` method. The method also deletes the caches of child bindings of the absolute binding.

> **i Note**
>
> There must be no pending property changes for a binding and its child bindings when calling the `refresh` method. Use the binding's `hasPendingChanges` method to check for pending changes before you delete the cache.

You can refresh all bindings with `ODataModel.refresh`, see ODataModel.refresh in the Demo Kit.

Refresh a single entity

You can refresh a **single** entity by calling `sap.ui.model.odata.v4.Context#refresh` or the bound context or return value context of an `sap.ui.model.odata.v4.ODataListBinding` which corresponds to this entity. This also refreshes all dependent bindings of its contexts.

Example

Usage of Context#refresh for a context in a list binding

```
onRefreshSelectedSalesOrder : function () {
    // within a sap.m.Table bound to a OData V4 list binding get the OData V4
context for the selected entity
    var oSalesOrderContext =
this.byId("SalesOrders").getSelectedItem().getBindingContext();

    if (!oSalesOrderContext.hasPendingChanges()) {
        oSalesOrderContext.refresh();
    }
},
```

Note

- Contexts of an `sap.ui.model.odata.v4.ODataListBinding` and the bound context of an `sap.ui.model.odata.v4.ODataContextBinding` can only be refreshed if the binding is not relative to a `sap.ui.model.odata.v4.Contex` and if its root binding is not suspended.
- Refresh is only allowed if there are no pending changes for the context and all its dependent bindings. If you have a relative binding with changes and this binding loses its context, the former parent binding does not report pending changes: the changes are kept, but the relation between these bindings is lost. You can do the following:
  - To find out if there are pending changes, use `sap.ui.model.odata.v4.ODataModel#hasPendingChanges`.
  - To save the changes, use `sap.ui.model.odata.v4.ODataModel#submitBatch`, and to delete the changes, use `sap.ui.model.odata.v4.ODataModel#resetChanges`.
  - If you set a context at the relative binding, the new parent binding will report the pending changes again.

Allow removal of a single entity when refreshing

After updating an entity, it may no longer match the query options for the collection which loaded the entity, in particular `$filter`. You can decide whether the refresh on the context of a list binding should ignore the query options or not: The corresponding context may be removed from the list binding for the collection by setting the parameter `bAllowRemoval` to `true`.

Note that changes to the list like a different sort order require a refresh of the whole list.

An example can be seen in the SalesOrders application. The table has a filter applied to show only the sales orders with *Life Cycle Status = "New"*. When confirming a sales order, its status will change to *In Process* and does not match the filter anymore. This sales order is then refreshed and will be removed from the list as the `bAllowRemoval` flag is set to `true`. This is shown in the following code snippet:

Example

refresh with allow removal

```
oAction.execute("confirmSalesOrderActionGroup").then(function () {
    oConfirmedSalesOrderContext.refresh(undefined, true); // bAllowRemoval =
true
});
```

For details, see ODataListBinding.refresh, ODataContextBinding.refresh and ODataPropertyBinding.refresh in the Demo Kit.

Example: Absolute and relative bindings created by an XML view

```
<Table items="{
 path : '/SalesOrderList',
 parameters : {
  $expand : 'SO_2_BP',
  $select : 'BuyerName,CurrencyCode,GrossAmount,Note,SalesOrderID'
 }}">
 ...
 <items>
  <ColumnListItem>
   <cells>
    <Text text="{SalesOrderID}"/>
    <Text text="{SO_2_BP/CompanyName}"/>
    <Text text="{BillingStatus}"/>
   </cells>
  </ColumnListItem>
 </items>
</Table>
<Table items="{
 path : 'SO_2_SOITEM',
 parameters : {
    $select: "DeliveryDate,GrossAmount,SalesOrderID"
 }
>
...
</Table>
```

The above sample shows an absolute list binding: A table's `items` aggregation is bound to `/SalesOrderList` using the `$expand` and `$select` query options as binding parameters. The columns define relative bindings with paths `SalesOrderID`, `SO_2_BP/CompanyName`, and `BillingStatus` with the absolute list binding as parent binding.

> **i Note**
>
> The `BillingStatus` remains empty and logs an error to the browser console as this structural property is not part of the `$select` specified for the list binding.

The lower table for the line items has a relative binding. As it has parameters defined, it triggers its own data service request once it receives its binding context.

Property Binding to Metadata

You can use `##` in a property binding's path to branch from data into metadata.

Example: Determine label from the corresponding annotation for property `GrossAmount`

```
<SimpleForm binding="{/SalesOrderList('42')}">
    <Label text="{GrossAmount##@com.sap.vocabularies.Common.v1.Label}" />
    <Text text="{GrossAmount}" />
</SimpleForm>
```

For details, see `sap.ui.model.odata.v4.ODataModel#bindProperty`.

Property Binding With an Object Value

A property binding can have an object value, if the target type specified in the corresponding control property's binding info is "any" and the binding is relative or points to metadata. In case it points to metadata, the binding's mode has to be `OneTime`, see sap.ui.model.BindingMode

Example: Using the controller method `'formatPhoneNumbersAsCSV'` to show a comma-separated list of phone numbers for business partner contacts

```
<SimpleForm binding="{/BusinessPartnerList('42')}">
    <Label text="Phone number list" />
    <Text text="{path : 'BP_2_CONTACT', mode : 'OneTime', targetType : 'any',
formatter : '.formatPhoneNumbersAsCSV'}" />
</SimpleForm>
```

For details,

For details, see `sap.ui.model.odata.v4.ODataModel#bindProperty`.

Side Effects

Editing properties of an entity sometimes causes side effects on other properties within the same or a related entity. Normally, a `PATCH` request which sends the user's input to the server includes side effects for the same entity (if relevant for the UI) within its response. Sometimes, however, an application needs more control on how and when this happens, or needs side effects on related entities as well.

You can use sap.ui.model.odata.v4.Context#requestSideEffects to load side effects when implicit loading is switched off via the binding-specific parameter `$$patchWithoutSideEffects`. This method must only be called on the bound context of a context binding, or on the return value context of an operation binding. Collection-valued navigation properites are fully supported, so an efficient request is sent instead of a simple refresh. The event `validateFieldGroup` provides a suitable point in time to request side effects after a certain group of fields has been changed. The annotation `com.sap.vocabularies.Common.v1.SideEffects` describes side effects and the API strikes a balance between the generic use based on this annotation and specific hard-coded uses. When requested from the V4 OData meta model, the annotations value looks as follows:

```
{
    "SourceEntities" : [{
        "$NavigationPropertyPath" : ""
    }, ...],
    "SourceProperties" : [{
        "$PropertyPath" : "Name"
    }, ...],
    "TargetEntities" : [{
        "$NavigationPropertyPath" : "DraftAdministrativeData"
    }, ...],
    "TargetProperties" : [{
        "$PropertyPath" : "DraftAdministrativeData/InProcessByUser"
    }, ...]
}
```

The `sap.ui.model.odata.v4.Context#requestSideEffects` API requires a single array as parameter, namely the concatenation of `TargetEntities` and `TargetProperties`.

The binding-specific parameter `$$patchWithoutSideEffects` can be set on context bindings and list bindings. If the parameter is not specified in a relative binding, the parameter value from the parent binding is used.

Parameters

When creating a binding, you can provide a parameter map which can contain the following:

- OData query options; the values determine parameters for data service requests triggered by the binding. For more information about these options, see OData Version 4.0 Part 2: URL Conventions, 5 Query Options .
- Binding-specific parameters start with `"$$"` and influence the behavior of the binding as follows:
- - `$$canonicalPath`: Set to `true` to use the canonical path computed from the path of the binding's context in the read URL for data service requests. All values other than `true` lead to an error.
  - `$$groupId` and `$$updateGroupId`: see Batch Control [page 952]
  - `$$noPatch`: In a property binding, set to `true` to prevent changes of the value to appear in back-end requests.
  - `$$operationMode`: see Filtering [page 939] and Sorting [page 942]
  - `$$ownRequest`: Set to `true` to ensure the binding uses an own service request to read data. All values other than `true` lead to an error.

The binding's OData query options are combined with the query options passed to the OData V4 model; the binding's query options overwrite model query options with the same name. The resulting query options are appended to each data service request by this binding. The following query options are supported; all others are not allowed and lead to an error:

- OData custom query options except those with the name prefix `"sap-"`. For more information about these, see OData Version 4.0 Part 2: URL Conventions, 5.2 Custom Query Options .
- The list and context binding support the OData system query options `$apply`, `$count`, `$expand`, `$filter`, `$orderby`, `$search` and `$select`.

The query option `$count` must be specified as a boolean value with `true` or `false`. All other query options can be specified with a string value. In addition to strings, the following alternatives are possible:

- `$select` can be specified as an array of strings where each string specifies a select item, or the value `'*'` to select all properties. Normally, these items point to direct parts of the query result without further expanding into related entities.Further options are available with Automatic determination of $expand and $select [page 937].
- `$expand` can be an object where each object property corresponds to an expand item: the key is the complete expand path. The value can be set as follows:
  a) `true` or `null` if no `expand` options are required
  b) An object with query options for the `$expand`; numeric options (like `$levels`) may be given as numbers. If the option is `$expand` or `$select`, the value may again be an object or array.

Example: Binding with parameters in JavaScript

```
oView.byId("SalesOrderTable").bindItems({
    path : "/SalesOrderList",
    parameters : {
        "$count" : true,
```

```
        "$expand" : {
            "SO_2_SOITEM" : {
                "$orderby" : "ItemPosition",
                "$select" : ["ItemPosition", "Quantity", "QuantityUnit",
"SalesOrderID"]
            }
        },
        "$filter" : "BuyerName ge 'M'",
        "$orderby" : "GrossAmount desc",
        "$select" : ["BuyerName", "CurrencyCode", "GrossAmount", "Note",
"SalesOrderID"]
    }
});
```

Example: Binding with parameters in an XML view (`$select` and `$expand` values as string)

```
<Table growing="true" growingThreshold="5" id="SalesOrders"
    items="{
            path : '/SalesOrderList',
            parameters : {
                $count : true,
                $expand : 'SO_2_BP',
                $filter : 'BuyerName ge \'M\'',
                $orderby : 'GrossAmount desc',
                $select : 'BuyerName,CurrencyCode,GrossAmount,Note,SalesOrderID'
            },
        }">
```

Example: Binding with parameters in an XML view (`$select` and `$expand` values as object)

```
<Table growing="true" growingThreshold="5" id="SalesOrders"
    items="{
            path : '/SalesOrderList',
            parameters : {
                $count : true,
                $expand : {
                       'SO_2_SOITEM' : {
                              '$orderby' : 'ItemPosition',
                              '$select' :
['ItemPosition','Quantity','QuantityUnit','SalesOrderID']
                       }
                },
                $filter : 'BuyerName ge \'M\'',
                $orderby : 'GrossAmount desc',
                $select :
['BuyerName','CurrencyCode','GrossAmount','Note','SalesOrderID']
            },
        }">
```

`changeParameters` allows to change, add, or delete OData query options. This does **not** apply, however, to binding-specific parameters that start with `$$`.

The parameters are changed according to the given map of parameters: Parameters with an undefined value are removed, the other parameters are set, and missing parameters remain unchanged. Change, add or delete is possible at the same time. The binding is refreshed as soon as the parameter changes are applied.

Example: Change binding parameters in JavaScript

```
oView.byId("SalesOrderTable").getBinding("items").changeParameters({
    "$search" : '"mountain bike"',
    "$filter" : undefined
});
```

Binding Collection Inline Count

The OData V4 model allows for binding the inline count of the entity collection read by an `ODataListBinding` which has the parameter `$count` set to `true`. In the example below, the table title is bound to `"$count"`, thus representing the number of sales order entities in the collection bound to the table.

Example: Table with title bound to `$count`

```
<Table id="SalesOrders"
    items="{
        path : '/SalesOrderList',
        parameters : {
            $count : true,
        }
    }"
>
    <headerToolbar>
        <Toolbar>
            <content>
                <Title id="SalesOrdersTitle" text="{$count} Sales Orders"/>
            </content>
        </Toolbar>
    </headerToolbar>
    ...
</Table>
```

The `ODataListBinding` provides a header context which holds header information like inline count for the list. Set the binding context for the relative property binding with path `"$count"` to the header context, see ODataListBinding.getHeaderContext. With this, the property binding's value is the list's inline count.

Example: Setting the header context for a property binding to $count

```
setHeaderContext : function () {
    var oView = this.getView();
    oView.byId("SalesOrdersTitle").setBindingContext(
        oView.byId("SalesOrders").getBinding("items").getHeaderContext());
}
```

> **i Note**
>
> The header context needs to be set when the list binding has been resolved, for example after a relative binding has been given its context with `sap.ui.base.ManagedObject#setBindingContext` or by binding on a parent element with `sap.ui.core.Element#bindElement`. In case the list binding is resolved initially, it is sufficient to set the header context in `sap.ui.core.mvc.Controller#onBeforeRendering`.

> **i Note**
>
> A property binding bound to the path `"$count"` may be part of a control hierarchy. When a parent control receives a different binding context than the list's header context, this binding context is propagated to the property binding. The property binding then fails to read its value as the context is not the header context and a console error is written.
>
> Example: On selection in the *Sales Orders* table, the application controller code sets the binding context of the table for the corresponding *Sales Order Items* table with relative binding path `"SalesOrderItems"` to the context corresponding to the selected sales order. The title of the *Sales Order Items* table which is bound to `"$count"` fails to read its value.

To circumvent this issue, proceed as follows:

1. Define the `ODataModel` as an additional named model with a specific name, such as `"headerContext"`.
2. Bind the property binding to this model using the path `"headerContext>$count"`.
3. Set the property binding's context with the model name `"headerContext"`.

To see this solution for the above example, search for `"headerContext"` in the code of the *OData V4 "Sales Orders"* sample app.

Type Determination

The property binding automatically determines the appropriate type depending on the property's metadata, unless a type is specified explicitly. For example, the binding `"{DeliveryDate}"` will determine the type `sap.ui.model.odata.type.DateTimeOffset` (assuming the metadata specifies "Edm.DateTimeOffset" for this property), but `"{path : 'DeliveryDate', type : 'sap.ui.model.odata.type.String'}"` uses the hardcoded type `sap.ui.model.odata.type.String` instead (and does not require metadata). You cannot specify format options or constraints unless you also hardcode the type.

Automatic type determination will take constraints from metadata into account, namely the OData property facets "MaxLength", "Nullable", "Precision" and "Scale". In addition to the OData property facets, the following OData V4 annotations are considered to set type constraints on automatic type determination:

- `Org.OData.Validation.V1.Validation.Minimum`, `Org.OData.Validation.V1.Validation.Maximum` and `Org.OData.Validation.V1.Validation.Exclusive` are used to set the constraints `minimum`, `maximum`, `minimumExclusive` and `maximumExlusive` for `sap.ui.model.odata.type.Decimal`.
- `com.sap.vocabularies.Common.v1.IsDigitSequence` is used to set the constraint `isDigitSequence` for `sap.ui.model.odata.type.String`.

> **i Note**
>
> Only constant expressions are supported to determine the annotation value in this case.

Currently, the types "Edm.Boolean", "Edm.Byte", "Edm.Date", "Edm.DateTimeOffset", "Edm.Decimal", "Edm.Double", "Edm.Guid", "Edm.Int16", "Edm.Int32", "Edm.Int64", "Edm.SByte", "Edm.Single", "Edm.String" and "Edm.TimeOfDay" are supported and mapped to the corresponding type in the namespace `sap.ui.model.odata.type`. All other types, including collections, are mapped to the generic type `sap.ui.model.odata.type.Raw` which can only be used to access the raw model value "as is", but not to convert it to a human readable representation. This allows specialized controls to work with types that would otherwise not be supported.

For more information, see the sap.ui.model.odata.type and sap.ui.model.odata.type.Raw API documentation in the Demo Kit.

> **i Note**
>
> By default, a property binding delivers a value formatted according to the target type of the control property it applies to, for example, “boolean” in case of `<Icon src="sap-icon://message-warning"`

`visible="{path : 'DeliveryDate', formatter : '.isOverdue'}">`. This leads to errors because type determination adds the correct type for the `DeliveryDate` property which is `DateTimeOffset` and cannot format its value as a boolean value. In such cases, use `targetType : 'any'` as follows:

```
<Icon src="sap-icon://message-warning" visible="{path : 'DeliveryDate',
targetType : 'any', formatter : '.isOverdue'}">
```

In rare cases, you might also want to specify a different `targetType`, for example `string`, `boolean`, `int`, or `float`. For more information how these values relate to OData types, see the sap.ui.model.odata.type API documentation or explore the XML Templating: UI5 OData Types sample in the Demo Kit. For more information about `targetType`, see the sap.ui.base.ManagedObject#bindProperty API documentation in the Demo Kit.

Binding Modes

The OData V4 model supports one-time binding, one-way binding and two-way binding modes (see sap.ui.model.BindingMode in the Demo Kit). The two-way binding mode is the **default** binding mode of the OData V4 model. You can use the `setDefaultBindingMode` method on the model to change the binding mode. For more information, see setDefaultBindingMode in the Demo Kit.

Suspend and Resume

You can suspend a `list binding` or `context binding` with its suspend method. A suspended binding does not send data service requests nor does it fire change events. You can only suspend absolute bindings or bindings which are quasi-absolute. A quasi-absolute binding is a relative binding with a context which is not a `sap.ui.model.odata.v4.Context`. You can only suspend a binding which is not yet suspended. For a relative binding having a V4 context, you may suspend the **root binding** of its binding hierarchy which is the (quasi-) absolute ancestor binding of this binding. The binding's method `getRootBinding` provides the root binding; for (quasi-) absolute bindings it returns the binding itself.

You can resume a suspended list or context binding with its `resume` method.

Typical use cases for suspend and resume are:

1. **Trigger read requests for controls in the view later not when the view is initialized:**
   In some situations you may want to suppress OData requests and change events triggered by an OData V4 binding for a certain period of time. This is useful for value help dialogs, such as the value help for the `/BusinessPartnerList` when creating a sales order in the `SalesOrders OData V4 sample`.
2. **UI adaptation at runtime:**
   The UI is adapted by adding or removing a column to a table or a field to a form; the "auto-$expand/$select" feature recomputes the $expand and $select query options when the corresponding list binding or context binding is suspended before adaptation and resumed afterwards.

> **Note**
>
> The template for the aggregation in a UI5 control cannot be adapted afterwards. That's why the aggregation has to be "bound again" after applying changes to the table template. For example. for a `sap.m.Table`, you have to call its `bindItems` method.

3. **Avoid intermediate request when modifying the binding multiple times**
   You want to add a filter and change the sorting of a list binding. If the binding is not suspended, it will trigger a request after calling the `filter` method, and a second request after calling the `sort` method. If it is suspended, only one request with the updated filter and sort criteria is sent on `resume`.

The code below shows a snippet from the `SalesOrders OData V4 sample` which delays the request to `/BusinessPartnerList` until the *Create Sales Order* dialog is displayed.

> **Note**
>
> The `suspended` flag in the binding info triggers a call to the suspend method of the corresponding binding once it is created.

> **Example**
>
> View

```
<Dialog id="CreateSalesOrderDialog" title="Create New Sales Order">
...
    <Input id="NewBuyerID" suggestionItems="{path : '/BusinessPartnerList',
suspended : true}">
        <suggestionItems>
            <core:ListItem key="{BusinessPartnerID}"
additionalText="{CompanyName}"  text="{BusinessPartnerID}"/>
        </suggestionItems>
    </Input>
...
</Dialog>
```

The controller code to open the dialog resumes the list binding on `/BusinessPartnerList` and thus triggers the request.

> **Example**
>
> Controller

```
var oBPListBinding = this.byId("NewBuyerID").getBinding("suggestionItems");

if (oBPListBinding.isSuspended()) {
    oBPListBinding.resume();
}
```

When a binding is suspended, all methods which may trigger CRUD requests for this binding, for example `ODataListBinding.create` throw an error. This is also true for dependent bindings of a suspended binding. However methods that cause the binding to be refreshed completely are allowed. These methods are:

- `ODataContextBinding.changeParameters`
- `ODataContextBinding.refresh`
- `ODataListBinding.changeParameters`

- ODataListBinding.refresh
- ODataListBinding.filter
- ODataListBinding.sort
- ODataListBinding.setAggregation
- ODataListBinding.updateAnalyticalInfo

> ⚠ Caution
>
> It is not allowed to suspend operation bindings.

Context API

The OData V4 model's list and context bindings create `sap.ui.model.odata.v4.Context` objects, which enhance `sap.ui.model.Context` and provide the following methods:

- `getObject` or `getProperty` provide synchronous and `requestObject` or `requestProperty` provide asynchronous access to values; the methods to access a property can provide the value in internal or external format
- `getBinding` retrieves the binding which created the context
- `getIndex` returns the context's list index provided the context has been created by an `ODataListBinding`
- `created` returns a promise that resolves after the successful creation of the new entity in the back end
- `delete` deletes an entity
- `getCanonicalPath, requestCanonicalPath` determines the "canonical path" of an entity
- `hasPendingChanges` tests for pending changes
- `isTransient` tests whether a new entity exists on the client-side only
- `refresh` refreshes an entity
- `requestSideEffects` loads the side effects of a PATCH
- `setProperty` asynchronously sets a property value. This is even possible without reading data first, in which case `If-Match : *` is used. You can also set a property without sending a PATCH request by using `null` as a group ID, but only if data has been read before.

> ℹ Note
>
> For `getObject` and `requestObject`, the data is cloned if the given path points to a non-primitive type. This ensures that internal OData model values cannot be modified.
>
> When a property is read in external format, the format is solely determined by the type defined in the OData meta data of the property, and not by the type or formatter specified for the binding.

```
// assume oEvent is an event fired when a button is pressed in an item of a
table bound to /SalesOrderList
sOrderID =
oEvent.getSource().getBindingContext().getProperty("SalesOrderID"); // the
SalesOrderID in the same item
// get a value in external format e.g. "1.234,23" instead of 1234.23
sGrossAmount = oEvent.getSource().getBindingContext().getProperty("GrossAmount",
true);
```

For more information, see sap.ui.model.odata.v4.Context in the Demo Kit.

Accessing Data in Controller Code

In the OData V4 model, bindings are used to access and modify backend data also if the data is accessed or modified in controller code.

You can create bindings that are independent of controls using the factory methods sap.ui.model.odata.v4.ODataModel.bindContext, sap.ui.model.odata.v4.ODataModel.bindList, and sap.ui.model.odata.v4.ODataModel.bindProperty.

Contexts

sap.ui.model.odata.v4.Context is central for CRUD operations in the controller code. `sap.ui.model.odata.v4.Context` provides the following functions:

- `requestObject`: Returns a promise on the value for the given path relative to the context.
- `requestProperty`: Returns a promise on the property value for the given path relative to the context.
- `getObject`: Returns the value for the given path relative to this context
- `getProperty`: Returns the property value for the given path relative to this context.
- `setProperty`: Sets a new value for the property identified by the given path.

Lists

A list binding is obtained either with `sap.ui.model.odata.v4.ODataModel.bindList`, or by getting an existing list binding bound to a control. Entities of the list can be requested using sap.ui.model.odata.v4.ODataModel.ODataListBinding.requestContexts. The function returns a promise resolving with an array of the requested contexts. The data of each context can be accessed using the `requestObject`, `requestProperty`, `getObject`, and `getProperty` methods of `sap.ui.model.odata.v4.Context`. To modify the data, `sap.ui.model.odata.v4.Context.setProperty` can be used.

```
var oList = oModel.bindList("/SalesOrderList");
oList.requestContexts(10, 20).then(function (aContexts) {
    aContexts.forEach(function (oContext) {
        // As we have fetched the data already, we can access "Note" through
getProperty
        var sNote = oContext.getProperty("Note");
        if (!sNote) {
            oContext.setProperty("Note", "No notes");
        }
    });
});
```

New entities can be created with sap.ui.model.odata.v4.ODataModel.ODataListBinding.create. It is not required to read existing records before.

```
var oList = oModel.bindList("/SalesOrderList"),
    oNewContext = oList.create();
```

Single Entities

A context binding is obtained either with sap.ui.model.odata.v4.ODataModel.bindContext, or by getting an existing context binding from the control tree. Data can be accessed through the bound context, see sap.ui.model.odata.v4.ODataContextBinding.getBoundContext. Using `sap.ui.model.odata.v4.ODataContextBinding.requestObject` is a short cut for `oBinding.getBoundContext().requestObject()`. sap.ui.model.odata.v4.Context.setProperty is used to modify data.

> **i** Note
>
> Relative bindings need to be resolved meaning that a context must have been set before data access is possible.

```
var oContextBinding = oModel.bindContext("/SalesOrderList('0500000000')");
oContextBinding.requestObject("Note").then(function (sNote) {
    if (!sNote) {
        oContextBinding.getBoundContext().setProperty("Note", "No notes");
    }
});
```

Single Properties

The access to single properties may either be done using a context binding as described above in the *Single Entities* section, or by using a property binding. The property binding is obtained with sap.ui.model.odata.v4.ODataModel.bindProperty, or by getting an existing property binding bound to a control. The value can be requested using sap.ui.model.odata.v4.ODataPropertyBinding.requestValue. A synchronous access is possible with sap.ui.model.odata.v4.ODataPropertyBinding.getValue, if the value is already available.

The value of a property binding can be modified using `sap.ui.model.odata.v4.ODataPropertyBinding.setValue`.

```
var oNote = oModel.bindProperty("/SalesOrderList('0500000000')/Note");

oNote.requestValue().then(function (sValue) {
    // do something with sValue
    // Note: We cannot use setValue as oNote is an absolute property binding
});
```

Automatic determination of $expand and $select

With automatic determination of `$expand` and `$select` ("auto-$expand/$select" in short), the OData V4 Model computes `$expand` and `$select` query options for service requests from binding paths specified for control properties. This has the following advantages:

1. You don't have to add or change `$select` or `$expand` in the binding parameters yourself.
2. Auto-$expand/$select only selects data needed for the UI, so that you get a minimal response size and improved performance.

You switch on auto-$expand/$select by setting the flag `autoExpandSelect` during model construction.

It is still possible to specify `$expand` and `$select` in the binding parameters. This is useful if you need to access properties which are not bound on the UI. When auto-$expand/$select is switched on, you may add any path to a simple or structured property to `$select`, even if this path contains navigation properties. The binding converts this `$select` to a `$expand` if necessary. It is not possible to change `$expand` and `$select` via the binding's changeParameters API. You don't have to specify **key properties** in the binding's `$select` parameter if they aren't bound on the UI. These are selected automatically because keys are required in many scenarios, for example, to compute the edit-URL to update an entity.

In auto-$expand/$select mode, a parent binding aggregates the binding paths and query options of its child bindings in its `$select` and `$expand` options, so that they do not send own data services requests. This aggregation is only possible in the following cases:

1. If the request for the parent binding is **not sent** and the child binding is a list or context binding which has only OData system query options in its parameters, or is a property binding.
2. If the request for the parent binding is **already sent** and the request already contains the aggregation for the child binding in its `$expand` and `$select`.

In other cases the child binding is not aggregated and sends an own request.

The list binding for the table in the following sample leads to the following request (reduced to `$expand` and `$select` parameters):

```
SalesOrderList?$select=BuyerName,LifecycleStatus,Note,SalesOrderID&
$expand=SO_2_BP($select=BusinessPartnerID,CompanyName)
```

```
<Table items="{/SalesOrderList}"
  ...
  <items>
    <ColumnListItem>
      <cells> <Text text="{BuyerName}"/> </cells>
      <cells> <Text text="{SO_2_BP/CompanyName}"/> </cells>
      <cells> <Input enabled="{= %{LifecycleStatus} === 'N' }" value="{Note}"/>
</cells>
    </ColumnListItem>
  </items>
</Table>
```

If you use a list binding with factory function with auto-$expand/$select, you need to specify the binding parameters `$expand` and `$select` for all properties that may be needed by the factory function.

> **i Note**
>
> During automatic determination of `$expand` and `$select` the factory function is called with a "virtual" context, that returns `undefined` for `getProperty` calls.

For auto-$expand/$select the model metadata must be analyzed before sending the request. This allows further optimization of the request, also enabling access to the parent entity by reducing partner navigation properties in the path.

Example: A view shows a sales order together with its line items, with a line item binding that is relative to the sales order binding. Any property binding relative to the line item can then access a property of the sales order without causing a `$expand`. This even works if the property is needed only after the sales order data has been requested. This feature can be used to control the visibility or editability of a line item property based on the state of the sales order, or for value help at the line item.

This path reduction of partner navigation properties is also performed in `sap.ui.model.odata.v4.Context#requestSideEffects`, so that side effects on the sales order can be requested via the context of a line item.

Binding Events

The OData V4 model supports certain events intended for applications, and others that are to be used for controls, as outlined in this section.

Events for Applications

For applications, the OData V4 model supports the following events:

- The `dataRequested` and `dataReceived` events are typically used by applications to display and hide a busy indicator or to process a back-end error which happened when requesting data. The events are fired by `ODataPropertyBinding`, `ODataContextBinding` and `ODataListBinding` when reading data:
  - The `dataRequested` event is fired directly after data has been requested from a back end.
  - The `dataReceived` event is fired after the back-end data has been processed. Note that the `dataReceived` event is also fired after a back-end request has failed. The error of the failed request is passed to the event handler as an `error` parameter.

  For more details, see the corresponding API documentation for the specific bindings ODataPropertyBinding, ODataContextBinding and ODataListBinding in the Demo Kit.
- The `createSent` and `createCompleted` events at the `ODataListBinding` are typically used by applications to lock the UI for the created entity to avoid modifications while the data for the created entity is sent to the back end, but the response from the back end is not yet processed on the client. For each `createSent` event, a `createCompleted` event is fired.
  - The `createSent` event is fired each time a POST request that is triggered for an `ODataListBinding#create` is sent to the backend.
  - The `createCompleted` event is fired each time the backend has responded to a POST request triggered for an `ODataListBinding#create`.

  For more information, see `ODataListBinding#create`.
- The `patchSent` and `patchCompleted` events are typically used by applications that are using update groups with submit mode Auto (which is the default) and which need to be informed when PATCH requests are sent to the back end and when they are processed. For example, these events can be used to display a `DraftIndicator` to inform the user that his changes are being saved and when saving is finished.

The `patchSent` and `patchCompleted` events are fired by `ODataContextBinding` and `ODataListBinding` if they send their own service request:

- The `patchSent` event is fired when the first PATCH request for this binding is sent to the backend.
- The `patchCompleted` event is fired when the backend has responded to the last PATCH request for this binding.

If `ODataContextBinding` and `ODataListBinding` use the service request of a superordinate binding, the events are fired by the superordinate binding.
For more details, see the corresponding API documentation for the specific bindings ODataContextBinding and ODataListBinding in the Demo Kit.

Events for Controls

The events `change` and `refresh` are meant for controls only, and not available for app development. They indicate that the respective binding has new data which can be accessed by the control:

- When the binding is initialized, it fires a `change` event with the parameter `reason` set to `sap.ui.model.ChangeReason.Change`.
- When a relative binding gets a new context, it fires a `change` event with the parameter `reason` set to `sap.ui.model.ChangeReason.Context`.
- When a binding is refreshed, the event fired depends on the binding type, as follows:
  a) `ODataPropertyBinding` and `ODataContextBinding` fire a `change` event with the parameter `reason` set to `sap.ui.model.ChangeReason.Refresh`.
  b) `ODataListBinding` fires a `refresh` event.

For more details, see the corresponding API documentation for the specific bindings ODataPropertyBinding, ODataContextBinding and ODataListBinding, as well as sap.ui.model.ChangeReason in the Demo Kit.

sap.ui.model.ChangeReason

Filtering

The OData V4 Model supports server side filtering on lists.

To use server side filtering, set the operation mode to sap.ui.model.odata.OperationMode.Server. This can be done as follows:

- For a single `ODataListBinding` instance, set the binding parameter `$$operationMode`
- For all list bindings of the model, set the model parameter `operationMode`.

Example: Operation mode set in `manifest.json` for the model

```
"models" : {
    "" : {
        "dataSource" : "default",
        "settings" : {
            "operationMode" : "Server",
            "synchronizationMode" : "None"
        }
    }
}
```

Example: Operation mode set as binding parameter for a specific list binding

```
<Table growing="true" growingThreshold="5" id="Equipments"
    items="{
            path : '/Equipments',
            parameters : {
                $$operationMode : 'Server',
                $filter : 'Category eq \'Electronics\'',
                $select : 'Category,EmployeeId,ID,Name'
            }
        }">
```

The `ODataListBinding` allows to set static and dynamic filters:

- To set a static filter, use the `$filter` system query option in the binding parameters. The static filter value is sent with every data service request for the binding; you may specify any filter value allowed in OData V4. The static filter cannot be overwritten for an existing binding.
- The dynamic filter is an instance of sap.ui.model.Filter , or an array thereof. For an array, the filters are combined with a logical AND. You can set the initial value for the dynamic filter in ODataModel.bindList or declaratively in an XML view with the `filters` property in an aggregation's binding information. To set the dynamic filter, use the ODataListBinding.filter method. This filter overwrites the initial value specified on binding construction.

The `ODataListBinding` combines the dynamic filter and static filter with a logical AND.

Examle: Dynamic and static filters

```
<Table growing="true" growingThreshold="5" id="Equipments"
    items="{
            path : '/Equipments',
            parameters : {
                $$operationMode : 'Server',
                $filter : 'Category eq \'Electronics
\'',                            <-- static filter
                $select : 'Category,EmployeeId,ID,Name'
            },
            filters : {                                          <-- dynamic filter
initial value
                path : 'EmployeeId',
                operator : 'GE',
                value1 : '0000'
            }
        }">
```

The example above filters the `Equipments` entity set by `Category` (static filter) and `EmployeeId` (dynamic filter, initial value).

Filtering with Any and All

The OData V4 model also supports the Lambda Operators `any` and `all` as defined in section 5.1.1.10 of the OData Version 4.0. Part 2: URL Conventions specification. They are represented by sap.ui.model.Filter objects with filter operators sap.ui.model.FilterOperator.Any and sap.ui.model.FilterOperator.All.

Example:

```
sap.ui.model.Filter({
        // the path of the collection for which the condition needs to be
evaluated
        path : "TEAM_2_EMPLOYEES",
        // either sap.ui.model.FilterOperator.Any or
sap.ui.model.FilterOperator.All
        operator : sap.ui.model.FilterOperator.Any,
        // any OData identifier which is a variable for the current element of
the collection referenced by path
        variable : "employee",
        // the filter condition; the path of the nested filter contains the
variable as prefix to reference current element of the collection
        condition : new sap.ui.model.Filter("employee/AGE",
sap.ui.model.FilterOperator.GT, 42)
    })
```

The path of the filter object is the path of the collection for which the boolean condition needs to be evaluated. The variable can be any OData identifier and it needs to be part of the path of a nested filter condition.

Filter Operator any

The filter operator Any applies the `boolean` filter condition to each member of the collection referenced by `path`. If the condition is true for **at least one** member of the collection, the any-filter matches. The filter with the Any operator without a filter condition matches only if the collection referenced by path is not empty.

Example 1: Get all teams that have at least one employee who is older than 42

```
oTeamsBinding.filter(
    new sap.ui.model.Filter({
        path : "TEAM_2_EMPLOYEES",
        operator : sap.ui.model.FilterOperator.Any,
        variable : "employee",
        condition : new sap.ui.model.Filter("employee/AGE",
sap.ui.model.FilterOperator.GT, 42)
    });
);
```

The resulting request would be: `http://host/service/TEAMS?$filter=TEAM_2_EMPLOYEES/any(employee:employee/AGE gt 42)`

Example 2: Get all teams that have at least one employee assigned

```
oTeamsBinding.filter(
    new sap.ui.model.Filter({
        path : "TEAM_2_EMPLOYEES",
        operator : sap.ui.model.FilterOperator.Any
    });
);
```

The resulting request would be: `http://host/service/TEAMS?$filter=TEAM_2_EMPLOYEES/any()`

Filter Operator all

The filter operator All applies the `boolean` filter condition to each member of the collection referenced by `path`. If the condition is true for **all** members of the collection, the all-filter matches.

Example: Get all teams for which all employees are older than 42.

```
oOrdersListBinding.filter(
    new sap.ui.model.Filter({
        path : "TEAM_2_EMPLOYEES",
        operator : sap.ui.model.FilterOperator.All,
        variable : "employee",
        condition : new sap.ui.model.Filter("employee/AGE",
sap.ui.model.FilterOperator.GT, 42)
    });
);
```

The resulting request would be: `http://host/service/TEAMS?$filter=TEAM_2_EMPLOYEES/all(employee:employee/AGE gt 42)`

sap.ui.model.odata.OperationMode.Server

Sorting

The OData V4 model supports server side sorting on lists.

To use server side sorting, set the operation mode to sap.ui.model.odata.OperationMode.Server as described unter Filtering [page 939].

`ODataListBinding` allows to set static and dynamic sorters:

- For setting a static sorter, the `$orderby` system query option in the binding parameters is used. The static sorter value is sent with every data service request for the binding. The static sorter cannot be overwritten for an existing binding.
- The dynamic sorter is a sap.ui.model.odata.Sorter instance, or an array thereof in which case the sorters are concatenated. You can set the initial value for the dynamic sorter in ODataModel.bindList, or declaratively in an XML view with the sorter property in an aggregation's binding information. For setting the dynamic sorter, the ODataListBinding.sort method is used. The sorter that is given here overwrites the initial value specified on binding construction.

Dynamic sorters are transformed to an OData `$orderby` system query option value and the static sorters are always appended as secondary sort criterion. In this example, the equipments are first ordered by `Category` (dynamic sorter) and then by `Name` (secondary sort criterion, static sorter). For a description of the `group` property, see getGroup.

Example: Dynamic and static sorters

```
#js
<Table growing="true" growingThreshold="5" id="Equipments"
    items="{
```

```
            path : '/Equipments',
            parameters : {
                $$operationMode : 'Server',
                $orderby : 'Name',                                  <-- static sorter
                $select : 'Category,EmployeeId,ID,Name'
            },
            sorter : {                                          <-- dynamic sorter;
can be overwritten by calling sort on the list binding
                path : 'Category',
                group : true                                    <-- optional, see
parameter vGroup of sap.ui.model.Sorter
            }
        }">
```

In this example, the equipments are first ordered by `Category` (dynamic sorter) and then by `Name` (secondary sort criterion, static sorter).

Value Lists

The OData V4 model supports the access to value list metadata and data.

Value lists enable you to read the possible values for a given property, such as `Category` in the `Product` entity type. A value list is typically visualized as a dropdown list, or as a value help dialog, that is, a popup with additional features such as filters which help finding the correct value. For performance reasons, you can reduce the service `$metadata` document size by outsourcing value list information to value list services. Consequently, the value list information is accessed in two steps:

1. Determine the value list type that is available for a given property via `ODataPropertyBinding.requestValueListType` without loading the value list service. This is typically called to determine the visualization of this property.
   The `sap.ui.model.odata.v4.ValueListType`, that the promise delivers, can have the following values:
   - `None`: No value list exists.
   - `Fixed`: One enumeration of fixed values exists.
   - `Standard`: A dynamic value list with multiple queries including selection criteria exists.
2. Determine the value list detail information on demand via `ODataPropertyBinding.requestValueListInfo` which returns a map of all annotations `com.sap.vocabularies.Common.v1.ValueList` or `com.sap.vocabularies.Common.v1.ValueListMapping` by qualifier. Each mapping has the `ValueListMappingType` type as specified in the OData 4.0 Common Vocabulary, see OData 4.0 Vocabularies - SAP Common. Each mapping is enriched by a `$model` property of type `sap.ui.model.odata.v4.ODataModel` which can be used to access the value list metadata and retrieve value list data.
   For value lists of type `Fixed`, only one mapping is expected and the qualifier is ignored. The mapping is available with key "".

Additionally, you can use the synchronous method `ODataPropertyBinding.getValueListType` if the metadata for the property is already available. If this is not the case, an exception is thrown. The API is available in `sap.ui.model.odata.v4.ODataMetaModel` analogously for use cases where controls are not yet in place, for example, during XML templating.

Example: Retrieving the value list type for a property

```
#js
       onModelContextChange : function (oEvent) {
        var oBinding = this.getBinding("value");

        if (oBinding && oBinding.isResolved()) {
            oBinding.requestValueListType().then(function (sValueListType) {

                // render the control depending on the value list type and
attach the below
                // event handler onValueHelp which is invoked when the user
requests value help

                switch (sValueListType) {
                    case ValueListType.Standard:
                        ...
                        break;
                    case ValueListType.Fixed:
                        ...
                        break;
                    case ValueListType.None:
                        ...
                        break;
                }
                that.setAggregation("field", oField);
            });
        }
    },
...
    onValueHelp : function (oEvent) {
        var oBinding = this.getBinding("value");

        oBinding.requestValueListInfo().then(function (mValueListInfo) {
            // this assumes value list type "Fixed"
            var oValueListMapping = mValueListInfo[""],
                oValueListMetaModel = oValueListMapping.$model.getMetaModel();

            ...
        ]);
    },
...
```

The `ValueList` Annotation

There are two options to place the `ValueList` annotation:

- In the value list service (the preferred way): When adding a value list for a property, the OData service only contains an annotation with the property as target and the term com.sap.vocabularies.Common.v1.ValueListReferences pointing to the metadata of the value list service. The ValueList annotation itself is in the referenced service. It must not have the properties CollectionRoot and SearchSupported.
- In the OData service itself: In this case, the `ValueList` annotation must have the property `CollectionRoot` pointing to the metadata of the value list service. The annotation `com.sap.vocabularies.Common.v1.ValueListReferences` is not needed.
  The disadvantage of this solution is that the complete value list information for all properties of the service is preloaded when the application is initialized.

OData Operations

The OData V4 model supports OData operations (`ActionImport`, `FunctionImport`, bound `Actions` and bound `Functions`). Unbound parameters are limited to primitive values.

Simple Function Bindings

You gain access to a `FunctionImport` by binding it to a view element. If there are no parameters and there is no need to control the point in time when the function is called, you can simply bind the OData path like this:

```
<Text text="{path: '/GetNumberOfAvailableItems()', type:
'sap.ui.model.odata.type.Int16'}"/>
```

This binding path represents the function's return value. The model calls the function immediately when a control requests this value.

The type must be specified if the return value is a primitive type.

Deferred Operation Bindings

Often it is not feasible for the operation to be called immediately, for example if there are parameters that the user has to enter first. In such cases, use an ODataContextBinding as element binding at a layout element in the view, for example a `<Form>` or a `<VBox>` (see the ODataContextBinding API documentation in the Demo Kit). Mark the operation as **deferred** by inserting an ellipsis ("...") in the brackets, for example `GetNextAvailableItem(...)`. Access the return value from child elements using relative bindings. When used like this, the context binding is called an **operation binding** or more specifically, a **function binding** or **action binding** depending on the type of OData operation it is used for.

If the operation binding defers operation execution, you need to call its `execute` method to execute the operation. See below for an example.

View:

```
<Form id="getNextAvailableItem" binding="{/GetNextAvailableItem(...)}">
```

```
    <Label text="Description"/>
    <Text text="{Description}"/>
    <Button text="Call the function" press="onGetNextAvailableItem"/>
</Form>
```

Controller:

```
onGetNextAvailableItem : function (oEvent) {
    this.getView().byId("getNextAvailableItem").getObjectBinding().execute();
}
```

In the above example, the function import is bound to a form (which has an ID that we need later). The text field showing a property of the result is a child of this form. It has a relative binding to the property `"Description"`.

If the function returns a primitive value or a collection, the binding for the result must be `"{value}"` as shown in the 2 examples below:

View:

```
<Form id="getNumberOfAvailableItems" binding="{/GetNumberOfAvailableItems(...)}">
    <Label text="Number of available items:"/>
    <Text text="{value}"/>
    <Button text="Call the function" press="onGetNumberOfAvailableItems"/>
</Form>
```

```
<VBox id="getAvailableItems" binding="{path : '/GetAvailableItems(...)',
parameters : {$select : 'ProductName', 'ProductId'}}">
    <List id="xyz" items="{value}">
        <items>
            <ObjectListItem title="{ProductName}" />
        </items>
    </List>
</VBox>
```

`execute` returns a promise which is resolved if the operation was successful and rejected with an error if this was not the case. Note that the promise is **not** fulfilled with the action's result: Use dependent bindings to access the result.

`refresh` is silently ignored on a deferred function binding as long as it has not yet been executed. Afterwards, a `refresh` calls the function again.

Action Bindings

Action bindings must be deferred, otherwise the application cannot control when the action is executed. A deferred action binding is declared exactly like a deferred function binding:

View:

```
<Form id="Submit" binding="{/Submit(...)}">
    <Button text="Submit the action" press="onSubmit"/>
</Form>
```

You append "(...)" even though the action's resource URL does not contain them. However, they are needed to mark the binding as deferred. In `execute`, the binding uses the metadata to distinguish between action and function and to build the correct operation resource path.

`refresh` is always silently ignored on a deferred action binding to prevent the action from being executed accidentally (for example by calling the `refresh` method on the ODataModel instance `oModel.refresh()`).

Operation Parameters

You can use the parameters of a deferred operation binding inside an XML view.

The parameters are addressed by the path prefix "$Parameter". This can either be done by binding each control property via the path prefix "$Parameter" (Option 1) or by having an outer binding with a "$Parameter" path (Option 2).

> **i Note**
>
> The path "$Parameter" must not be added directly to the path of a deferred operation binding. A deferred operation binding is identified by an ellipsis at the end of the path.

This is how to bind each property without a "$Parameter" context:

View:

> **Example**
>
> Binding parameters to a dialog (Option 1)

```
<Dialog binding="{/ChangeTeamBudgetByID(...)}" id="operation1" title ="Change
Team Budget">
    <buttons>
        ...
    </buttons>
    <form:SimpleForm>
        <Label text="TeamID" />
        <Input value="{$Parameter/TeamID}" />
        <Label text="Budget" />
        <Input value="{$Parameter/Budget}" />
    </form:SimpleForm>
</Dialog>
```

Alternatively, you may bind the entire form to the `$Parameter` context:

View:

> **Example**
>
> Binding parameters to a dialog (Option 2)

```
<Dialog binding="{/ChangeTeamBudgetByID(...)}" id="operation2" title="Change
Team Budget">
    <buttons>
        ...
    </buttons>
    <form:SimpleForm binding="{$Parameter}">
        <Label text="TeamID" />
        <Input value="{TeamID}" />
        <Label text="Budget" />
        <Input value="{Budget}" />
    </form:SimpleForm>
</Dialog>
```

In either case, the values of the parameters are set using the model binding of the control, with no need to write any application code.

Alternatively, operation parameters can be set by calling the function `setParameter` on the operation binding, as shown in this example:

Controller:

```
onSubmit : function (oEvent) {
    this.getView().byId("Submit").getObjectBinding().setParameter("Comment",
sComment).execute();
}
```

The API method `getParameterContext` can be used to access parameters in controller code, see also Accessing Data in Controller Code [page 935]

The example below demonstrates how a budget may be modified depending on the `TeamID`:

Controller:

Example

Reading parameter values using the parameter context

```
adaptBudgetToTeam : function (){
    var oDialog = this.oView.byId("operation2"); // the second dialog in the
paragraph before
        oParameterContext = oDialog.getObjectBinding().getParameterContext();

    if (oParameterContext.getProperty("TeamID') === "STARTUP") {
        oParameterContext.setProperty("Budget", 555.55);
    else {
        oParameterContext.setProperty("Budget", 123.45);
    }
}
```

Note

The parameter context is only defined if the operation binding is resolved.

Bound Actions and Functions

So far, the examples always used operations at root level, addressed via an action import or function import. However, it is also possible to bind an action or a function to another resource of the service. This can be an entity, a collection of entities or an entity property.

Bound actions or functions are controlled in the same way as unbound operations; append `(...)` to the binding path for the control's property.

To call actions or functions bound to a single entity, entity property, or navigation property use a relative binding. The following sample calls the "invoice created" action on the sales order selected in the corresponding table:

```
var oModel = this.getView().getModel(),
```

```
    oTable = this.getView().byId("SalesOrders"),
    oSalesOrderContext = oTable.getSelectedItem().getBindingContext(),
    oAction = oMoodel.bindContext("name.space.InvoiceCreated(...)",
oSalesOrderContext);

oAction.execute().then(
    function () {
        MessageToast.show("Invoice created for sales order " +
oSalesOrderContext.getProperty("SalesOrderID"));
    },
    function (oError) {
        MessageBox.alert(oError.message, {
            icon : MessageBox.Icon.ERROR,
            title : "Error"});
        });
    }
);
```

To call actions or functions bound to a collection specified by an OData entity set, you can create a context binding with an absolute path, or with a relative path for the operation (for example `name.space.DestroyOutdated(...)`") and the header context of a list binding as parent context. The following sample shows a button press event handler which calls the `destroy outdated` action on the `LeaveRequests` entity set.

```
var oModel = this.getView().getModel();

oModel.bindContext("/LeaveRequests/name.space.DestroyOutdated(...)").execute();
```

The same example with a relative binding and the header context of the list binding as parent context:

```
var oModel = this.getView().getModel(),
    // assume there is a table with ID "leaveRequests" and its items aggregation
bound to "/LeaveRequests"
    oListBinding = this.byId("leaveRequests").getBinding("items"),
    oHeaderContext = oListBinding.getHeaderContext();
oModel.bindContext("name.space.DestroyOutdated(...)", oHeaderContext).execute();
```

> **i Note**
>
> - The path of an operation binding may also start with a navigation property.
>   Example: The operation binding has a relative path `BP_2_PRODUCT/name.space.Change(...)`. You set its binding context from the selected item in a table bound to `/BusinessPartners`. When you call `execute` on the operation binding, the "change" action is executed with the selected business partner's navigation property `BP_2_PRODUCT` as binding parameter.
> - The parent binding of a deferred operation must not be a deferred operation itself.

Advertised Operations

According to the OData 4.0 specification ("11.5.2 Advertising Available Operations within a Payload") services may return available actions and functions bound to a particular entity as part of the entity representation within the payload. Data for an advertised operation within an entity is sent as property starting with `#<namespace>.<action>` of that entity. If the entity does not advertise the operation, it does not contain this property. To access the advertised operation in a binding, the same format has to be used. See the following example:

Example

Enable a button to trigger an action `AcSetIsOccupied` available on entity type of entity set `EMPLOYEES` depending on advertisement of this action on the entity `EMPLOYEES('1')`

```
<FlexBox binding="{/EMPLOYEES('1')}">
    <Button text="Set occupied" enabled="{= !!%
{#com.sap.gateway.default.iwbep.tea_busi.v0001.AcSetIsOccupied} }"/>
</FlexBox>
```

Here a button is enabled only if the action `AcSetIsOccupied` is advertised for the entity `EMPLOYEES('1')`. The `%` operator is used to set the internal type to `any` because the advertised action is sent as an object. The double negation `!!` converts this object to a boolean value that is needed by the `enabled` control property.

If no advertised action was returned in the payload, `undefined` (or `null` in OData 4.01 in case of advertised non-availability) is returned as value for the binding. This translates to false in the expression above.

If there is an additional list of non-binding parameter names to identify a specific overload, then they need to be given in the binding path as well, for instance: `%{#Model.RemainingVacation(Year)}`.

Note

The bound action advertisement is added to $select automatically if the model parameter `autoExpandSelect` is set.

To access the metadata of an operation, the double hash (`##`) syntax has to be used as is illustrated in the next example:

Example

Binding against metadata of an action

```
var oContext = oModel.createBindingContext("/EMPLOYEES('1')/
##com.sap.gateway.default.iwbep.tea_busi.v0001.AcSetIsOccupied");
var oMetaModel = oContext.getModel();
oMetaModel.requestObject("0/$ReturnType/$Type", oContext).then(alert);
```

Here a context is created pointing to the metadata of the action and afterwards the type is accessed using this context.

This approach can also be used with XML templating where `createBindingContext` is called internally.

Access Operation Results

You can access the results of the operation by calling `getObject()` from the bound context.

```
// let oOperation be the operation's context binding
oOperation.execute().then(function () {
    // Note: execute does not deliver the results
    var oResults = oOperation.getBoundContext().getObject();
    ...
});
```

The promise returned by the operation binding's `execute` method may resolve with a *return value context* provided the conditions specified in `execute` are met. The operation binding may be bound to an entity or a collection of entities.

The typical use case for *return value context* is when you call a bound operation with a context `C1` defining its binding parameter and the bound operation returns a *different version* of the entity used as binding parameter. `C1` is the binding context of an "object page" container displaying properties of the corresponding entity. You need to replace `C1` as binding context of the object page by the *return value context*. This way, the *different version* of the entity is displayed without a further read request. If the bound operation returns the entity used as binding parameter, the changes will automatically be copied to the binding parameter.

If the operation binding fulfills the conditions for returning a context, you can set the parameter `$$inheritExpandSelect` for the binding: The request for the bound operation is then sent with the same `$expand` and `$select` query options used to load the operation's binding parameter. This way you guarantee that all fields of the object page are available in the operation response.

Sample object page to display an `Artist` entity

```
<form:SimpleForm id="objectPage">
    <Toolbar>
        <Button text="Edit" enabled="{IsActiveEntity}" press=".onEdit"/>
    </Toolbar>
    <Label text="ID"/> <Text text="{ArtistID}"/>
    <Label text="Is Active"/> <Text text="{IsActiveEntity}"/>
    <Label text="Name"/> <Input value="{Name}" />
    ...
</form:SimpleForm>
```

Controller code to display the active version of `Artist 42` initially and switch to draft version on *Edit*

```
// display "active" version of artist initially
onInit : function () {
    var oActiveArtistContext = oModel
            .bindContext("/Artists(ArtistID='42',IsActiveEntity=true)")
            .getBoundContext();
    this.byId("objectPage").setBindingContext(oActiveArtistContext);
},

// display the "inactive" version of the entity returned by the "EditAction"
onEdit : function () {
    var that = this;
    oModel.bindContext("name.space.EditAction(...)",
this.byId("objectPage").getBindingContext(), {$$inheritExpandSelect : true})
        .execute()
        .then(function (oInactiveArtistContext) {
            that.byId("objectPage").setBindingContext(oInactiveArtistContext);
        });
}
```

OData Version 4.0 Part 1, 11.5 Operations
ODataContextBinding

Batch Control

OData V4 allows you to group multiple operations into a single HTTP request payload, as described in the official OData V4 specification Part 1, Batch Requests (see the link under Related Information for more details).

The OData V4 model sends requests in the following cases:

- **Implicit read requests** to retrieve data for a binding
  Example: A list binding with the absolute path `/SalesOrderList` triggers a `GET SalesOrderList` to read data.
- **Implicit update requests** via two-way binding
  Example: Update a sales order's note through a property binding with the relative path `Note`, which has a context with path `/SalesOrderList(SalesOrderID='42')` triggering `PATCH SalesOrderList(SalesOrderID='42')` with the note's value as JSON payload.
- **Explicit requests** triggered through API calls like `ODataListBinding.refresh` or `ODataContextBinding.execute`

For each of these cases, it is possible to specify a group ID of type `string`.

A group ID has one of the following submit modes to control the use of batch requests:

- `sap.ui.model.odata.v4.SubmitMode.API` - Requests associated with the group ID are sent in a batch request via `sap.ui.model.odata.v4.ODataModel#submitBatch` .
- `sap.ui.model.odata.v4.SubmitMode.Auto` - Requests associated with the group ID are sent in a batch request which is triggered automatically before rendering.
- `sap.ui.model.odata.v4.SubmitMode.Direct` - Requests associated with the group ID are sent directly without batch.

The following group IDs are possible:

- `"$auto"` and `"$auto.*"`: Predefined batch group ID which is the default if no group ID is specified. You can use different `$auto.*` group IDs to use different batch requests. The suffix can be any non-empty string consisting of alphanumeric characters from the basic Latin alphabet, including the underscore. They have the submit mode `sap.ui.model.odata.v4.SubmitMode.Auto`.
- `"$direct"`: Predefined batch group ID which has the submit mode `sap.ui.model.odata.v4.SubmitMode.Direct`. For more information, see Performance Aspects [page 967].
- An application group ID is a non-empty string consisting of alphanumeric characters from the basic Latin alphabet, including the underscore. By default, an application group has the submit mode `sap.ui.model.odata.v4.SubmitMode.API`. It is possible to use a different submit mode; for details see section Define submit mode for an application group ID [page 955].

To specify the group ID for implicit requests, use the parameters `$$groupId` (group ID for read requests) and `$$updateGroupId` (group ID for update requests) for the binding which triggers the request (see the ODataModel.bindList, ODataModel.bindContext and ODataModel.bindProperty API documentation).

Batch requests for update groups with a submit mode different from `$direct` are queued per group ID. A batch request with changes is only sent if the previous batch request for the same group ID is returned and processed. In this case, all submitted changes for that group ID are combined in one batch request; changes associated with different calls to ODataModel.submitBatch use different change sets inside the batch request.

Code example: Updates for the sales order note through two-way binding will use the group ID `"myGroup"`, whereas data is read with the group `"$auto"`.

Batch group usage for binding created via JavaScript:

```
sap.ui.define(["sap/ui/model/odata/v4/ODataModel"], function (ODataModel) {
    var oModel = new ODataModel({serviceUrl : "/myService/",
synchronizationMode : "None"}),
        oContextBinding = oModel.bindContext("/
SalesOrderList(SalesOrderID='42')", /*oContext*/ undefined, {$$updateGroupId :
"myGroup"}),
        oPropertyBinding = oModel.bindProperty("Note",
oContextBinding.getBoundContext());
});
```

XML view sample: Declares controls which create the context binding (in the `SimpleForm`) and the property binding (in the `Input`) as sketched in the above JavaScript code sample.

Batch group usage for bindings created via XML view:

```
<form:SimpleForm binding="{path : '/SalesOrderList(SalesOrderID=\'42\')',
parameters : {$$updateGroupId : 'myGroup'}}" editable="true" ...>
    <Label labelFor="Note" text="Note" />
    <Input id="Note" value="{Note}" />
    ...
</form:SimpleForm>
```

On instantiation of an OData V4 model, you can provide both a group ID and an update group ID; they are used as defaults if the corresponding binding parameter is not specified. The default for the group ID is `"$auto"`. The value of group ID is used as a default for the update group ID.

For explicit requests, the group ID can be specified as an optional parameter to the corresponding API method. The group ID or update group ID of the binding is used as a default. For more information, see the ODataContextBinding.execute, ODataContextBinding.refresh, ODataListBinding.refresh, ODataPropertyBinding.refresh and ODataPropertyBinding.setValue API documentation in the Demo Kit.

Change Sets and Order of Requests Inside a Batch Request

The OData V4 model automatically puts all non-GET requests into a single change set, which is located at the beginning of a batch request. All GET requests are put after it. If there is only a single request within the change set, it is replaced by that single request when submitting the batch group (saves overhead on the wire). PATCH requests for the same entity are merged into a single request.

Resetting Property Changes

You can set an update group ID for a binding so that property changes are collected in a batch queue. The `ODataModel.submitBatch` method sends all these changes for a given batch group at once and the `ODataModel.resetChanges` method resets the changes. With these methods, you can, for example, implement a *Save* and a *Cancel* button for a form: *Save* triggers `submitBatch`, and *Cancel* triggers *resetChanges*.

> **i Note**
>
> The `resetChanges` method only resets all implicit update requests via two-way binding for the given group, while read requests or requests from `ODataContextBinding.execute` remain in the queue and are sent when the `submitBatch` method is called.

The list and context binding also offer the `resetChanges` method which resets changes for the binding and its child bindings.

> **i Note**
>
> The promise returned by `submitBatch` can be used together with the `hasPendingChanges` method to check whether changes were successfully persisted. `hasPendingChanges` exists for the ODataModel as well as for ODataListBinding, ODataContextBinding and ODataPropertyBinding. Note that the promise returned by `submitBatch` is only rejected if the complete batch request has failed.

Example: View

```
<Toolbar design="Transparent">
    <content>
        <Button icon="sap-icon://save" press="onSaveSalesOrder"/>
        <Button icon="sap-icon://sys-cancel-2" press="onCancelSalesOrder"/>
    </content>
</Toolbar>
<form:SimpleForm id="mySimpleForm" binding="{path: '/SalesOrderList(ID=\'42\')',
$$updateGroupId: 'SalesOrderUpdateGroup'}">
    <Label text="Sales Order ID" />
    <Text text="{SalesOrderID}" />
    <Label labelFor="Note" text="Note" />
    <Input id="Note" value="{Note}" />
</form:SimpleForm>
```

Example: Controller

```
onCancelSalesOrder : function (oEvent) {
    this.getView().getModel().resetChanges("SalesOrderUpdateGroup");
},

onSaveSalesOrder : function (oEvent) {
    var that = this;

this.getView().getModel().submitBatch("SalesOrderUpdateGroup").then(function(){
        if (!
that.byId("mySimpleForm").getBindingContext().getBinding().hasPendingChanges()){
            // raise success message
        }
    });
},
```

Repeating Property Changes

The OData V4 model automatically repeats failed property changes (PATCH requests). If the update group ID has SubmitMode.API and the property change of the entity on the server fails, the change is repeated with the next call of ODataModel.submitBatch for this group. If the update group ID has SubmitMode.Auto or

SubmitMode.Direct and the change fails, the change is repeated automatically with the next update for the entity. Since 1.67.0, ODataModel.submitBatch can also be used for update group IDs with SubmitMode.Auto in order to repeat, independently of an update.

The same holds true for Creating an Entity [page 974].

Define submit mode for an application group ID

On construction of the model, it is possible to specify the submit mode for application group IDs. This is useful when you want to separate requests requiring short processing time on the server from those requiring long processing time, so that responses to "fast" requests are visible earlier on the UI.

The following example shows how to set the submit mode `sap.ui.model.odata.v4.SubmitMode.Auto` for the group IDs `fastGroup` and `slowGroup` in the manifest.

Example

Specify the submit mode for an application group in manifest.json

```
"models" : {
    "" : {
        "dataSource" : "default",
        "settings" : {
            "operationMode" : "Server",
            "synchronizationMode" : "None",
            "groupProperties" : {
                "fastGroup" : {"submit" : "Auto"},
                "slowGroup" : {"submit" : "Auto"}
            }
        }
    }
```

Meta Model for OData V4

Each OData V4 model offers access via `getMetaModel` to a corresponding metadata model `sap.ui.model.odata.v4.ODataMetaModel`, which is read-only and offers access to OData V4 metadata in a streamlined JSON format (see links under Related Information for more details). Only one-time bindings are supported by this model because the metadata is immutable.

Synchronous vs. Asynchronous Access

Access to metadata is basically asynchronous (e.g. `requestObject`) to allow for dynamic loading of metadata. There is also a corresponding method for synchronous access (e.g. `getObject`) which returns `undefined` if metadata is not yet available. It should only be used in situations where metadata has already been loaded asynchronously before. Loading happens individually for each document, i.e. each $metadata document is loaded and processed as a whole and is available thereafter. Includes and references to other $metadata documents are not supported, only the service root's initial $metadata document can be used.

Path Syntax

The `requestObject` API documentation in the Demo Kit explains how metadata is accessed and the supported path syntax in great detail. The basic idea is that every path described in the specification OData Version 4.0 Part 3: Common Schema Definition Language, 14.2.1 Attribute Target is a valid absolute path within the metadata model if a leading slash is added; for example `"/" + "MySchema.MyEntityContainer/MyEntitySet/MyComplexProperty/MyNavigationProperty"`. For more information, see the requestObject API documentation in the Demo Kit.

Annotations

The main API for both programmatic access from JavaScript and declarative access from XML templating is `sap.ui.model.odata.v4.ODataMetaModel#getObject`. It works together with `sap.ui.model.odata.v4.ODataMetaModel#resolve` (for `<template:with>`) and `sap.ui.model.odata.v4.ODataMetaModel#bindList` (for `<template:repeat>`) in order to provide convenient access to annotations, inline as well as external targeting.

The OData meta model knows how to follow "14.2.1 Attribute Target" described in specification "OData Version 4.0 Part 3: Common Schema Definition Language " as well as "14.5.2 Expression edm:AnnotationPath", "14.5.11 Expression edm:NavigationPropertyPath", "14.5.12 Expression edm:Path", and "14.5.13 Expression edm:PropertyPath".

XML Templating [page 1018] still works the same as for V2, with some slight changes as outlined below:

- Metadata paths need to refer to the V4 metadata JSON structure.

- Note the difference between `"/TEAMS@Org.OData.Capabilities.V1.TopSupported"` and `"/TEAMS/@com.sap.vocabularies.Common.v1.Deletable"` (look closely at the slash!), see ODataMetaModel.requestObject.
- Use `sap.ui.model.odata.v4.AnnotationHelper` instead of `sap.ui.model.odata.AnnotationHelper`. The ability to follow a path has been built into the V4 OData meta model itself. See `field>Value/$Path@com.sap.vocabularies.Common.v1.Label` in the code example below. Instead of `sap.ui.model.odata.AnnotationHelper.format`, you can use `sap.ui.model.odata.v4.AnnotationHelper.value` or `sap.ui.model.odata.v4.AnnotationHelper.format`. You can use both as a computed annotation.
- Computed annotations start with "@@", for example `<Text text="{meta>Value/@@sap.ui.model.odata.v4.AnnotationHelper.value}" />`. Their name without the "@@" prefix refers to a function in the global namespace which computes an annotation value from the metadata addressed by the preceding path. For more information, see ODataMetaModel.requestObject .
- Ensure that the view is loaded asynchronously. In this case, there is no longer a need to preload metadata, because the template processor waits for every binding to be resolved before proceeding.
- Use a double hash ('##') or single hash ('#') separator to branch from the OData V4 model into metadata, see createBindingContext .

> **i Note**
>
> The single hash separator is deprecated since 1.52

> **→ Remember**
>
> An appropriate URI encoding is necessary for the data path (before the separator), but neither for the separator itself nor for the metadata path that follows it.

Example: `<template:with path="/Products('A%2FB%26C')/Name#@com.sap.vocabularies.Common.v1.Label" var="label">` or `<template:with path="data>/Products#/" var="productEntityType">`, etc.

Example of an OData V4 XML template:

```
<mvc:View
        template:require="{AnnotationHelper : 'sap/ui/model/odata/v4/
AnnotationHelper'}"
        xmlns="sap.m"
        xmlns:template="http://schemas.sap.com/sapui5/extension/
sap.ui.core.template/1">
    <template:alias name="format" value="AnnotationHelper.format">
    <template:alias name="value" value="AnnotationHelper.value">
        <template:with path="meta>/BusinessPartnerList/" var="entityType">
          <template:with path="entityType>@com.sap.vocabularies.UI.v1.LineItem"
var="lineItem">
            <Table headerText="Business Partners"
              items="{path : '/BusinessPartnerList', length : 5}">
              <columns>
                <template:repeat list="{lineItem>}" var="field">
                  <Column>
                    <template:if test="{field>Label}">
                      <template:then>
                        <Label design="{:= $
{field>@com.sap.vocabularies.UI.v1.Importance/$EnumMember}
                          === 'com.sap.vocabularies.UI.v1.ImportanceType/High' ?
'Bold' : 'Standard'}"
                          text="{field>Label}"/>
                      </template:then>
```

```
                      <template:else>
                        <Text text="{field>Value/
$Path@com.sap.vocabularies.Common.v1.Label}"/>
                      </template:else>
                    </template:if>
                  </Column>
                </template:repeat>
              </columns>
              <items>
                <ColumnListItem>
                  <cells>
                    <template:repeat list="{lineItem>}" var="field">
                      <template:with path="field>Value/$Path" var="target">
                        <template:if test="{= $
{target>@@AnnotationHelper.getValueListType} === 'Standard' }">
                            <template:then>
                                <Input value="{path : 'field>Value/@@value'}"
showValueHelp="true", valueHelpRequest=".onValueHelp"}" />
                            </template:then>
                            <template:elseif test="{= $
{target>@@AnnotationHelper.getValueListType} === 'Fixed' }">
                                <ComboBox value="{path : 'field>Value/@@value'}"
loadItems=".onLoadItems" showValueHelp="true" />
                            </template:elseif>
                            <template:elseif
test="{target>@com.sap.vocabularies.Common.v1.Text}">
                                <!-- Note: TextFirst, TextLast, TextSeparate,
TextOnly -->
                                <template:if test="{= $
{target>@com.sap.vocabularies.Common.v1.Text@com.sap.vocabularies.UI.v1.TextArran
gement/$EnumMember}
                                    ===
'com.sap.vocabularies.UI.v1.TextArrangementType/TextLast' }">
                                    <!-- Text: "A descriptive text for values of
the annotated property.
                                        Value MUST be a dynamic expression when
used as metadata annotation." -->
                                    <Text text="{field>Value/@@value}
{target>@com.sap.vocabularies.Common.v1.Text/@@value}" />
                                </template:if>
                            </template:elseif>
                            <template:else>
                                <Text text="{field>Value/@@format}" />
                            </template:else>
                        </template:if>
                      </template:with>
                    </template:repeat>
                  </cells>
                </ColumnListItem>
              </items>
            </Table>
          </template:with>
        </template:with>
    </template:alias>
    </template:alias>
</mvc:View>
```

AnnotationHelper

The module `sap/ui/model/odata/v4/AnnotationHelper` delivers the following computed annotations; require it as shown in the example above:

- `value` helps to convert annotations into corresponding expression bindings or similar. The resulting binding does **not** contain type and constraint information; both are detected automatically. For examples, see sap.ui.model.odata.v4.AnnotationHelper.value.
- `format` helps to convert annotations into corresponding expression bindings, or similar. Compared to `value`, `format` adds type and constraints information to the resulting binding. This is useful, for example, if the XML of the view is cached.
  If you use `format` with a path containing a single "$AnnotationPath" or "$Path" segment, the value corresponding to that segment is considered as a data binding path prefix whenever a dynamic "14.5.12 Expression edm:Path" or "14.5.13 Expression edm:PropertyPath" is turned into a data binding.
  For examples, see `format`.
  If `format` finds a `Org.OData.Measures.V1.ISOCurrency` or a `Org.OData.Measures.V1.Unit` annotation at a property, a composite binding with a `sap.ui.model.odata.type.Currency` or a `sap.ui.model.odata.type.Unit` type is generated. For more information, see Currencies and Units [page 986].
- `label` - Returns the value for the label of a `com.sap.vocabularies.UI.v1.DataFieldAbstract` from the meta model.
- `getValueListType` - Determines which type of value list exists for the property. The function returns a value from the enumeration `sap.ui.model.odata.v4.ValueListType`. It can be called directly on a property:

```
<template:with path="/BusinessPartnerList/Role" var="property">
    <template:if test="{= ${property>@@AnnotationHelper.getValueListType} ===
'Fixed'}">
        ...
    </template:if>
</template:with>
```

Alternatively it can be called on an annotation holding an `edm:Path` to a property when it is called in the context of an entity type. This is typically the case when iterating over a `com.sap.vocabularies.UI.v1.LineItem` annotation of an entity type and asking for value help on the data fields. See the example regarding `LineItem` of `BusinessPartnerList` (the relevant parts are repeated here):

```
<template:with path="meta>/BusinessPartnerList/" var="entityType">
  <template:with path="entityType>@com.sap.vocabularies.UI.v1.LineItem"
var="lineItem">
...
            <template:repeat list="{lineItem>}" var="field">
              <template:with path="field>Value/$Path" var="target">
                <template:if test="{= $
{target>@@AnnotationHelper.getValueListType} === 'Standard' }">
...
```

The first `<template:with>` defines `entityType` to be the type of the set `BusinessPartnerList`. The `<template:repeat>` iterates over its annotation `com.sap.vocabularies.UI.v1.LineItem` (a collection of records with type `com.sap.vocabularies.UI.v1.DataField`). The record's property `Value` is assumed to be an `edm:Path` pointing to a property of the entity type. For this path the value list type is determined.

OData V4 Metadata JSON Format

The OData V4 model provides access to metadata in a streamlined JSON format which is described in the section below.

It is different to the $metadata service's JSON format (see OData JSON Format Version 4.0) and the OData JSON Format for Common Schema Definition Language (CSDL) Version 4.0 (see corresponding specification), intended to simplify client-side processing.

In the sections below, angled brackets indicate variable parts. The numbers next to each expression correspond to the numbered sections in the official specification, see OData Version 4.0 Part 3: Common Schema Definition Language (CSDL) Plus Errata 03 . Comments highlight optional properties, especially those that have certain default values.

Design Rationale

We have prefixed constant property names with `"$"` as this is a legal first character for JavaScript identifiers, but not for OData simple identifiers. This way, **inline annotations** can be added via `"@<14.3.1 Annotation Term>#<14.3.2 Annotation Qualifier>" : <value>` everywhere without resulting in any naming conflicts. This is shown as `"@..." : <value>` below.

We assume that schema **aliases** have been resolved. We add a trailing dot after a schema's namespace, meaning qualified name "A.B" cannot clash with schema namespace "A.B.", for example. This trailing dot is also present for `"$Include"`, `"$TermNamespace"` and `"$TargetNamespace"` values.

`$kind` has been added to each object with a (qualified) OData name and to almost each object which can be annotated via external targeting, but not to enum members. Actions and functions are arrays of overloads and `$kind` has been added to each overload.

We assume each **enum member** has a value via the fallback rule "If no values are specified, the members are assigned consecutive integer values in the order of their appearance, starting with zero for the first member."

Facets like `MaxLength`, `Precision` and `Scale` are represented as numbers if possible (`"$Scale" : "variable"` is the only exception). `DefaultValue` is represented as a string for lack of type information in the general case. `"$MaxLength" : "max"` is omitted and will be treated the same as an unspecified length on the client-side.

A "17.5 **TargetPath**" used as "13.4.1 Attribute Path" or "13.5.3/13.6.3 Attribute EntitySet" is normalized in the following sense: a simple identifier is used instead of a target path for entity sets (or singletons) within the same container.

Each annotation specifies a value. Accordingly, `$DefaultValue` has been omitted for the time being.

Normalization: For all EDM elements which allow both inline annotations and external targeting, only external targeting is used. This affects edm:ActionImport, edm:ComplexType, edm:EntityContainer, edm:EntitySet, edm:EntityType, edm:EnumType, edm:FunctionImport, edm:Member, edm:Singleton, edm:Term, edm:TypeDefinition, edm:NavigationProperty, edm:Property. The goal is to reduce cases that contain a mixture of inline annotations and external targeting to the bare minimum. External targeting is possible for edm:Action, edm:Function, edm:Parameter, and edm:ReturnType via 4.01 style annotation targets, either in a way that applies to all overloads of the action or function or all parameters of that name across all overloads, or in a way that identifies a single overload.

We use the `"<key>@<14.3.1 Annotation Term>#<14.3.2 Annotation Qualifier>" : <value>` syntax for inline annotations in the following cases to avoid explicit object representations:

- "7.2 Element ReferentialConstraint" with key `"<7.2.1 ReferentialConstraint Property>"`
- "7.3 Element OnDelete" with key `"$OnDelete"`
- "14.3 Annotation" with key `"@<14.3.1 Annotation Term>#<14.3.2 Annotation Qualifier>"` (yes, this does lead to a double at-sign `"@...#...@...#..."`)
- "14.5.14.2 Element PropertyValue" with key `"<14.5.14.2.1 PropertyValue Property>"`

Metadata JSON Structure

The following JSON file represents the metadata document which corresponds to `GET <serviceRoot>/$metadata`:

```
{
  "$Version" : "<3.1.1 Edmx Version>",
  "$Annotations" : {
    "<14.2.1 Annotations Target>" : {
      // Note: "<14.3.2 Annotation Qualifier>" defaults to "<14.2.2 Annotations
Qualifier>",
      // qualifiers are optional, "#" is omitted then
      "@<14.3.1 Annotation Term>#<14.3.2 Annotation Qualifier>" : <value> //
constant or dynamic expression
      "@<14.3.1 Annotation Term>#<14.3.2 Annotation Qualifier>@..." : <value> //
annotation of an annotation
    }
  },
  "$EntityContainer" : "<5.1.1 Schema Namespace>.<13.1.1 EntityContainer
Name>", // root entity container for this $metadata document
  "$Reference" : {
    // server-relative, dereferencable URLs (to $metadata) only!
    "<3.3.1 Reference Uri>" : { "@..." : <value>,
      "$Include" : ["<3.4.1 Include Namespace>.", ...], // optional
      "$IncludeAnnotations" : [{
        "$TermNamespace" : "<3.5.1 IncludeAnnotations TermNamespace>.",
        "$Qualifier" : "<3.5.2 IncludeAnnotations Qualifier>", // optional
        "$TargetNamespace" : "<3.5.3 IncludeAnnotations TargetNamespace>." //
optional
      }, ...] // optional
    }
  }, // optional
  "<5.1.1 Schema Namespace>" : {
    "$kind" : "Schema",
    "@..." : <value> // place inline annotations for schema itself here!
  },
  "<5.1.1 Schema Namespace>.<8.1.1 EntityType Name>" : {
```

```
    "$kind" : "EntityType",
    "$BaseType" : "<8.1.2 EntityType BaseType>", // optional
    "$Abstract" : true, // omit in case of default value: false
    "$OpenType" : true, // omit in case of default value: false
    "$HasStream" : true, // omit in case of default value: false
    "$Key" : [
      "<8.3.1 PropertyRef Name>", // in case no Alias is given
      {"<8.3.1 PropertyRef Alias>" : "<8.3.1 PropertyRef Name>"},
      ...
    ], // optional
    "<6.1.1 Property Name>" : {
      "$kind" : "Property",
      "$Type" : "<6.1.2 Property Type>",
      "$isCollection" : true, // omit in case of default value: false
      "$Nullable" : false, // omit in case of default value: true
      "$MaxLength" : <6.2.2 MaxLength>, // optional, number
      "$Precision" : <6.2.3 Precision>, // optional, number
      "$Scale" : <6.2.4 Scale> | "variable", // optional, number or fixed string
      "$Unicode" : false, // omit in case of default value: true
      "$SRID" : "<6.2.6 SRID>", // optional
      "$DefaultValue" : "<6.2.7 DefaultValue>" // optional

  }
}
```

Constant and Dynamic Expressions

Constant and dynamic expressions are used as values for annotations. Their JSON representation is shown in the following two tables.

Table 32: Constant Expressions

Expression	Options	Additional Information

14.4 Constant Expressions	`{"$Binary" : "T0RhdGE"}`
	`{"$Date" : "2000-01-01"}`
	`{"$DateTimeOffset" : "2000-01-01T16:00:00.000-09:00"}`
	`{"$Decimal" : "3.14"}`
	`{"$Duration" : "P11D23H59M59.999999999999S"}`
	`{"$Guid" : "21EC2020-3AEA-1069-A2DD-08002B30309D"}`
	`{"$TimeOfDay" : "21:45:00"}`
		"Binary", "Date", "DateTimeOffset", "Decimal", "Duration", "Guid", "TimeOfDay" are objects with a single property that has a string value.

14.4.2 Expression `Bool`	`false` `true`	Is represented by the JavaScript boolean literals.
14.4.7 Expression `EnumMember`	`{"$EnumMember" : 42}` `{"$EnumMember" : "1234567890123456789"}`	Is represented like above object notation, but with a JavaScript number literal as long as the value is a safe integer, else with a string value.

Expression	Options	Additional Information

14.4.8 Expression `Float`	`3.1415926535`
	`{"$Float" : "-INF"}`
	`{"$Float" : "INF"}`
	`{"$Float" : "NaN"}`
		Is represented by a JavaScript number literal (except for the `nanInfinity` ABNF rule which needs an object notation with a string value).

14.4.10 Expression `Int`	`42` `{"$Int" : "1234567890123456789"}`	Is represented by a JavaScript number literal as long as the value is a safe integer. Else the above object notation is used.
14.4.11 Expression `String`	`"Product Catalog"`	Is represented by a JavaScript string literal.

Table 33: Dynamic Expressions

Expression	Options and Additional Information
14.5.1 Comparison and Logical Operators	edm:Not is written as `{"$Not" : <value>, "@..." : <value>}`. All others are written like `{"$And" : [<value>, <value>], "@..." : <value>}` because they require two child expressions.
14.5.2 Expression `AnnotationPath`	`{"$AnnotationPath" : "..."}`
14.5.3 Expression `Apply`	`{"$Apply" : [<value>, ...], "$Function" : "<14.5.3.1 Apply Function>", "@..." : <value>}`

14.5.4 Expression `Cast`	`{`
	`"$Cast" : <value>,`
	`"$isCollection" : true, // omit in case of default value: false`
	`"$Type" : "<14.5.4.1 Cast Type>",`
	`"$MaxLength" : <6.2.2 MaxLength>, // optional, number`
	`"$Precision" : <6.2.3 Precision>, // optional, number`
	`"$Scale" : <6.2.4 Scale> |`
	`"variable", // optional, number or fixed string`
	`"$SRID" : "<6.2.6 SRID>", // optional`
	`"@..." : <value>`
	`}`

14.5.5 Expression `Collection`	`[<value>, ...]` Simply an array. No additional properties, no annotations possible.

Expression	Options and Additional Information
14.5.6 Expression `If`	`{"$If" : [<value>, <value>, <value>], "@..." : <value>}` Condition, then, else (which is optional inside a "14.5.5 Expression Collection" only).
14.5.7 Expression `IsOf`	`{ "$IsOf" : <value>, "$isCollection" : true, // omit in case of default value: false "$Type" : "<14.5.7.1 IsOf Type>", "$MaxLength" : <6.2.2 MaxLength>, // optional, number "$Precision" : <6.2.3 Precision>, // optional, number "$Scale" : <6.2.4 Scale> | "variable", // optional, number or fixed string "$SRID" : "<6.2.6 SRID>", // optional "@..." : <value> }`
14.5.8 Expression `LabeledElement`	`{"$LabeledElement" : <value>, "$Name" : "<5.1.1 Schema Namespace>.<14.5.8.1 LabeledElement Name>", "@..." : <value>}`
14.5.9 Expression `LabeledElementReference`	`{"$LabeledElementReference" : "<QualifiedName name of a labeled element expression in scope>"}`

14.5.10 Expression `Null`	`null`
	`{"$Null" : null, "@..." : <value>}`
	The object notation is needed in case of inline annotations.

14.5.11 Expression `NavigationPropertyPath`	`{"$NavigationPropertyPath" : "..."}`
14.5.12 Expression `Path`	`{"$Path" : "..."}`
14.5.13 Expression `PropertyPath`	`{"$PropertyPath" : "..."}`
14.5.14 Expression `Record`	The record itself is a map: `{ "$Type" : "<14.5.14.1 Record Type>", "<14.5.14.2.1 PropertyValue Property>" : <value>, "@..." : <value> }`
14.5.15 Expression `UrlRef`	`{"$UrlRef" : <value>, "@..." : <value>}`

Performance Aspects

The OData V4 model offers the features described below which influence performance.

`odata.metadata=minimal`

The OData V4 model uses an `odata.metadata=minimal` header in its requests to reduce the amount of data that is sent from server to client. For more information, see section "3.1.1 odata.metadata=minimal" in the OData JSON Format Version 4.0 specification.

`$expand` and `$select`

An application can either specify `$expand` and `$select` parameters to read all data to be displayed in one request, or create bindings dynamically to load only part of the data with one request per binding. The application needs to decide whether to have less roundtrips with a bigger payload or more roundtrips with smaller payload.

To reduce payload, applications should only select properties that are needed using `$select` (see the code sample in the Parameters [page 928] topic). Besides the properties needed on the UI, the binding must select key properties to support features such as read requests sent from a child binding, write requests, or bound operations on the respective entity.

Batching Requests or Not

By default, the OData V4 model collects all requests made to the OData service in a batch request to reduce the number of roundtrips. The disadvantage of a batch request is that it cannot be cached by the browser. If some of the requests (e.g. value help requests) are "cacheable", it is a good idea to request these resources directly and use the browser cache to improve the performance of the application. In such cases, use the `$direct` group as described in the section Batch Control [page 952].

Binding Caches

Absolute bindings and also relative bindings, which fulfill certain conditions, have a cache that is used for their data. Once data is read, all value requests (e.g. those made by dependent relative bindings) are served by this cached data. `ODataListBinding` additionally supports paging. For more information about this, see Bindings [page 922].

Calling `refresh` on an absolute binding clears its cache as well as the caches of its relative child bindings. Calling `refresh` on the model refreshes all bindings that have been created by that model.

> → Tip
>
> Relative bindings have an own cache store cache by context. When you change the context of the relative binding and then switch back to the previous context, the latter context change will not lead to a data request as the cache holding this data is reused. This is useful for master-detail scenarios where selection in the master leads to setting the corresponding context in the relative binding for the detail. Entries in the master that have already been selected won't lead to a data request.
>
> **Note:** For the above mechanism to work, you must not recreate a relative binding as you then lose the cache for the previously selected contexts. Keep the binding and just set its context.

Early requests for metadata and security token

The requests for the service's root `$metadata` document and annotation files and for the security token may be on the "critical execution path": By default, these requests are sent lazily when the SAPUI5 application starts, for example. only when the corresponding information is needed. This delays application startup until these requests have returned.

If you construct the model with parameter `earlyRequests`, the requests are sent as early as possible and application startup performance may improve.

> i Note
>
> Modern browsers typically can process up to six parallel requests. Therefore it strongly depends on the number of requests sent initially by the application, if and how much the performance improves.

> → Remember
>
> The default value for `earlyRequests` is false in SAPUI5 version 1.54. It may, however, change to true in later releases: Do not rely on the default value and explicitly set it to false to ensure the requests are not sent early.

Unsupported Superclass Methods and Events

Certain methods derived from SAPUI5 model and binding superclasses are not supported in OData V4 model classes or have limited support.

The following methods and events are affected by this. For more information, see the corresponding API documentation for each method and event in the Demo Kit.

Table 34: Unsupported Methods

Class	Method

`sap.ui.model.odata.v4.ODataMetaModel`
(See sap.ui.model.odata.v4.ODataMetaModel in the Demo Kit)
	`bindTree`
	`getOriginalProperty`
	`isList`
	`refresh`
	`setLegacySyntax`

`sap.ui.model.odata.v4.ODataModel`
(See sap.ui.model.odata.v4.ODataModel in the Demo Kit)
	`bindTree`
	`destroyBindingContext`
	`getObject`
	`getOriginalProperty`
	`getProperty`
	`isList`
	`setLegacySyntax`

`sap.ui.model.odata.v4.ODataContextBinding` (See sap.ui.model.odata.v4.ODataContextBinding in the Demo Kit)	`isInitial` `refresh` (limited support only) `resume` (limited support only) `suspend` (limited support only)

`sap.ui.model.odata.v4.ODataListBinding`
(See sap.ui.model.odata.v4.ODataListBinding in the Demo Kit)
	`getDistinctValues`
	`isInitial`
	`refresh` (limited support only)
	`resume` (limited support only)
	`suspend` (limited support only)

Class	Method

`sap.ui.model.odata.v4.ODataPropertyBinding`
(See sap.ui.model.odata.v4.ODataPropertyBinding in the Demo Kit)
	`isInitial`
	`refresh` (limited support only)
	`resume`
	`setValue` (limited support only)
	`suspend`

Table 35: Unsupported Events

Class	Event

`sap.ui.model.odata.v4.ODataMetaModel`
(See sap.ui.model.odata.v4.ODataMetaModel in the Demo Kit)
	`parseError`
	`propertyChange`
	`requestCompleted`
	`requestFailed`
	`requestSent`

`sap.ui.model.odata.v4.ODataModel`
(See sap.ui.model.odata.v4.ODataModel in the Demo Kit)
	`parseError`
	`propertyChange`
	`requestCompleted`
	`requestFailed`
	`requestSent`

Changes Compared to OData V2 Model

This section outlines the main differences between the OData V2 and OData V4 models.

While some of the differences between the OData V4 model and the OData V2 model are due to features that have not yet been implemented, many differences are due to the following:

- Protocol incompatibility between OData V4 and OData V2
- API cleanup and simplification
- Adherence to OData V4 standards regarding the names and terms used in APIs

These differences will therefore remain even after all features have been implemented. The table below gives you an overview of these changes, as well as the reason behind them and (if applicable) how the OData V2 model mechanism is supported in the OData V4 model.

Change	Reason
Binding parameter names: The binding parameter name for an OData system query option is identical to the system query option name: `$expand`, `$select`, ... (V2 uses `expand`, `select`).	Simplification: The OData V4 model simplifies the binding parameter structure to just one map where all entries in the map are OData query options, with the exception of entries that have a key starting with "$$" (binding-specific parameters). In all cases, the names of the binding parameters are exactly the same as in the OData URL sent to the server.
The model does not support the methods `getData`, `getObject`, `getOriginalProperty`, `getProperty`. For data access, use the context API instead of methods on the model.	OData requires asynchronous data retrieval: Synchronous data access requires that data has already been loaded from the server. This means there is no way of knowing whether this already happened, meaning the result of a synchronous access method is quite often unpredictable. The OData V4 context API offers ansynchronous and synchronous access to the data of a specific context. It is no longer necessary to construct a path for data access as needed by the methods on the model. For more information, see the section *Context API* in Bindings [page 922].
Minimize APIs required for batch control: Model does not support the methods `getChangeBatchGroups`, `getChangeGroups`, `getDeferredGroups`, `setChangeBatchGroups`, `setChangeGroups`, `setDeferredBatchGroups`, `setDeferredGroups`, `setUseBatch` (and corresponding model construction parameters).	Simplification: Batch groups are solely defined via binding parameters with the corresponding parameters on the model as default. Application groups are by default deferred; there is no need to set or get deferred groups. You just need the `submitBatch` method on the model to control execution of the batch. You can use the predefined batch group `"$direct"` to switch off batch either for the complete model or for a specific binding (only possible for the complete model in V2). For more information, see Batch Control [page 952].
OData operations executed via binding: Model does not support the method `callFunction`.	Simplification: Use an operation binding instead; it is now much easier to bind operation execution results to controls.

Change	Reason
No CRUD methods on model: Model does not support the methods `create`, `read`, `remove`, `update`.	Simplification: `read`, `update`, `create` and `remove` operations are available implicitly via the bindings. Bindings can also be used without controls. It is not possible to trigger requests for specific OData URLs. For more information, see Accessing Data in Controller Code [page 935].
No metadata access via model: Model does not support methods `getServiceAnnotations`, `getServiceMetadata`, `refreshMetadata` as well as methods corresponding to the events `metadataFailed`, `metadataLoaded`.	Simplification: Metadata is only accessed via `ODataMetaModel`. Metadata is only loaded when needed (e.g. for type detection or to compute URLs for write requests); the corresponding methods on the `v4.ODataMetaModel` use promises instead of events.
sap.ui.model.odata.AnnotationHelper is not supported for OData V4.	Simplification: Much of the functionality in sap.ui.model.odata.AnnotationHelper is provided by sap.ui.model.odata.v4.ODataMetaModel and sap.ui.model.odata.v4.ODataModel. **Example** The path syntax supported by the v4.ODataMetaModel, see sap.ui.model.odata.v4.ODataMetaModel, method `requestObject` allows for navigation in the model's metadata; there is no need to use `AnnotationHelper` methods for this. You can find the remaining functionality in the OData V4 specific sap.ui.model.odata.v4.AnnotationHelper.

sap.ui.model.odata.v4.ODataModel

Additional Annotation Files

The OData V4 model supports loading of additional annotation files.

The annotation files have to be given during creation of an `ODataModel` instance. Adding annotation files at a later point in time is **not** supported.

The format of the annotation file has to be the same as the metadata file of the service. Only XML files are supported. You can specify the annotation files in the descriptor for applications, components, and libraries (`manifest.json`).

Annotation files are specified in `manifest.json` as follows:

```
"dataSources" : {
    "default" : {
        "uri" : "/sap/opu/odata4/IWBEP/V4_SAMPLE/default/IWBEP/
V4_GW_SAMPLE_BASIC/0001/",
        "type" : "OData",
        "settings" : {
            "annotations": ["localAnnotations"],
            "odataVersion" : "4.0"
        }
    },
    "localAnnotations": {
        "uri": "data/annotations.xml",
        "type": "ODataAnnotation"
    }
},
```

Annotation files are usually defined as data sources in `manifest.json`. In the example above, the annotation file is located relative to the component. In the `dataSource` definition of the OData service, you can reference these annotation data sources in the `annotations` setting. The content of the annotation files are then merged into the service metadata in the given order (the last one wins). Every (target, term, qualifier)-tuple must appear at most once within `$metadata` documents, but can be overwritten by annotation files.

Annotation terms are not merged, but replaced as a whole (“PUT” semantics). For example, if you have defined the sort restriction annotation `Org.OData.Capabilities.V1.SortRestrictions` at the `BusinessPartnerSet` as shown in the example below, you have to repeat the term in your annotation file if you want to add, for example, the additional property `AscendingOnlyProperties`.

The annotation term is specified in the service metadata document:

```
<Annotations Target="GWSAMPLE_BASIC.GWSAMPLE_BASIC_Entities/BusinessPartnerSet">
    <Annotation Term="Org.OData.Capabilities.V1.SortRestrictions">
        <Record>
            <PropertyValue Property="NonSortableProperties">
                <Collection>
                    <PropertyPath>BusinessPartnerID</PropertyPath>
                </Collection>
            </PropertyValue>
        </Record>
    </Annotation>
</Annotations>
```

If an additional property needs to be added, the term has to be repeated in the annotation file:

```
<Annotations Target="GWSAMPLE_BASIC.GWSAMPLE_BASIC_Entities/BusinessPartnerSet">
    <Annotation Term="Org.OData.Capabilities.V1.SortRestrictions">
        <Record>
            <PropertyValue Property="AscendingOnlyProperties">
                <Collection>
                    <PropertyPath>AnyPropertyPath</PropertyPath>
                </Collection>
            </PropertyValue>
            <PropertyValue Property="NonSortableProperties">
                <Collection>
                    <PropertyPath>BusinessPartnerID</PropertyPath>
                </Collection>
            </PropertyValue>
        </Record>
    </Annotation>
</Annotations>
```

Creating an Entity

The `sap.ui.model.odata.v4.ODataListBinding#create` method creates a new entity. Users can interact with a newly created entity even before it has been sent to the server.

To create new entities, `ODataListBinding#create` uses the list binding's update group ID as group ID. For more information how this group ID is determined, see the documentation for the binding-specific parameter `$$updateGroupID` of `ODataModel#bindList`.

A newly created entity can be inserted at the start or at the end of the list. This new entity is transient until it is successfully submitted, see `Context#isTransient`. The initial data for the created entity can be supplied via the parameter `oInitialData` and modified via property bindings. Properties that are not part of the initial data show the default value from the service metadata on the UI, but they are not sent to the server. If there is no default value, null is used instead, even if the property is not nullable. Updates for the transient entity are collected and added to the POST request which creates the entity on the server.

Inserting an entity at the end of the list is done via the `bAtEnd` parameter in the `create` call. This is only possible, if the list's length has been requested via the system query option `$count`.

To delete transient entities, use `Context#delete`. Transient entities are also deleted when you reset the changes for the list binding on which the entity has been created, see `ODataListBinding#resetChanges` and `ODataModel#resetChanges`. The promise returned by `Context#created` is rejected in all cases where the created entity is deleted before it is created in the backend. As long as the list binding has a transient entity, `ODataListBinding#hasPendingChanges` returns `true` and the following methods of `ODataListBinding` raise an error: `refresh`, `filter`, and `sort`. The deletion of another entity of the same list binding is possible.

> **i Note**
>
> The position of the created entity may change after the methods `refresh`, `filter`, or `sort` of an `ODataListBinding`.

If you have called `ODataListBinding#create` on a list binding where the update group ID has `SubmitMode.API` and the creation of the entity on the server fails, the creation is repeated with the next call of `submitBatch` for this group. If the update group ID has `SubmitMode.Auto` or `SubmitMode.Direct` and the creation fails, the creation is repeated automatically with the next update for the entity. `submitBatch` can also be used for update group IDs with `SubmitMode.Auto` to repeat, independently of an update. The error returned by the server is passed to the `MessageManager` and the promise you get via `Context.created` is not rejected. Each time the data for the created entity is sent to the server, a `Context.createSent` event is fired. Each time the client receives a response for the creation, a `Context.creatCompleted` event is fired, independent of whether the creation was successful, or not.

If you have called `ODataListBinding#create` on a list binding with an application group ID, and the creation of the entity on the server fails, the creation is repeated with the next call of `ODataModel#submitBatch` for this group. If the update group ID is `$auto` or `$direct`, and the creation fails, the creation is repeated automatically with the next update for the entity. The error is passed to the `MessageManager` and the promise you get via `Context#created` is not rejected. Each time the data for the created entity is sent to the server, a `createSent` event is fired. Each time the client receives a response for the creation, a `createCompleted` event is fired, independent of whether the creation was successful, or not.

→ Recommendation

Lock the UI each time the (`POST`) request for the creation is sent to the server and unlock it, when the response from the server for that (`POST`) request is processed, because updates in between result in errors. If the update group ID is `SubmitMode.API`, you can lock the UI when calling `ODataModel#submitBatch` and unlock it again when the promise returned by `ODataModel#submitBatch` is resolved or rejected. However, if the update group ID is `SubmitMode.Auto` or `SubmitMode.Direct`, use the `createSent` event to lock the related UI and the `createCompleted` event to unlock it.

```
// suppose this list binding has no own update group; it uses the model's update
group instead (an application group)
...
        onCreateSalesOrder : function (oEvent) {
            var oContext = this.getView().byId("SalesOrders").getBinding("items")
                    .create({
                        "Note" : "My new Sales Order",
                        "NoteLanguage" : "E",
                        "BuyerID" : "0100000000",
                        "CurrencyCode" : "EUR"
                    });

            // Note: This promise fails only if the transient entity is deleted
            oContext.created().then(function () {
                    // sales order successfully created
                }, function (oError) {
                    // handle rejection of entity creation; if oError.canceled
=== true then the transient entity has been deleted
                });
        },

        onDeleteSalesOrder : function () {
            var oSalesOrderContext =
this.getView().byId("SalesOrders").getSelectedItem().getBindingContext();

            oSalesOrderContext.delete("$auto").then(function () {
                    // sales order successfully deleted
                }, function (oError) {
                    // do error handling
                });
        },

        onSaveSalesOrder : function () {
            var oView = this.getView();

            function resetBusy() {
                oView.setBusy(false);
            }

            // lock UI until submitBatch is resolved, to prevent errors caused
by updates while submitBatch is pending
            oView.setBusy(true);

oView.getModel().submitBatch(oView.getModel().getUpdateGroupId()).then(resetBusy,
 resetBusy);
        },
...
```

> **i Note**
>
> To ensure that for a list binding all expanded data is available as soon as the promise returned by `Context#created` is resolved, an additional single `GET` request for the newly created entity is sent automatically once the `POST` request has arrived.
>
> If you want to skip this additional single `GET` request, call `ODataListBinding#create` with parameter `bSkipRefresh=true`.

The `promise` returned by `Context#created` is resolved when the entity represented by this context has been created in the backend. Once the promise is resolved, `Context#getPath` returns a path including the key predicate of the new entity. For returning the path including the key predicates, all key properties need to be available.

Deleting an Entity

The `Context.delete` method deletes an entity on the server and updates the user interface accordingly.

When you delete the entity from a list binding, the corresponding row is removed. When you delete the entity from a context binding, the binding and all dependent bindings lose the reference.

Example: Delete From a Table

```
onDeleteSalesOrder : function () {
    var oTable = this.getView().byId("SalesOrders"),
        oSalesOrderContext = oTable.getSelectedItem().getBindingContext();

    oSalesOrderContext.delete("$auto").then(function () {
        oTable.removeSelections();
        MessageBox.alert("Deleted Sales Order",
            {icon : MessageBox.Icon.SUCCESS, title : "Success"});
    }, function (oError) {
        MessageBox.alert("Could not delete Sales Order: "
            + oError.message, {icon : MessageBox.Icon.ERROR, title : "Error"});
    });
},
```

Consuming OData V2 Services with the OData V4 Model

The SAPUI5 framework can consume OData V2 Services in a non-intrusive way as if working directly with OData V4.

Overview

With SAPUI5 the OData V4 Model supports the consumption of OData V2 services. The framework takes care to convert the metadata and the data in a way that the application developer writes its application as he would do with an OData V4 model with a corresponding OData V4 service. As OData V4 supports various features that are not covered by OData V2, some features of the OData V4 model cannot be used. A list of the limitations is available below.

Here is an example of a manifest.json file, which shows how to configure your application to consume a V2 service with the V4 model.

```
{
    "_version" : "1.1.0",
    "sap.app" : {
        ...
        "dataSources" : {
            "default" : {
                "uri" : "<ODataV2 Service URL>",
                "type" : "OData",
                "settings" : {
                    "odataVersion" : "2.0"
                }
            }
        },
        ...
    },
    ...
    "sap.ui5" : {
        ...
        "dependencies" : {
            "minUI5Version" : "1.49",
            ...
        },
        "models" : {
            "" : {
                "dataSource" : "default",
                "settings" : {
                    "autoExpandSelect" : false,
                    "operationMode" : "Server",
                    "synchronizationMode" : "None"
                },
                "type" : "sap.ui.model.odata.v4.ODataModel"
            }
        },
        ...
    }
}
```

If you have an OData V2 service and you want to consume this service with an OData V4 model, you have to set `type` of the corresponding model to **`sap.ui.model.odata.v4.ODataModel`** and `odataVersion` of the corresponding data source to **`2.0`**. Both settings are needed. Additionally, the `minUI5Version` has to be at least **1.49**.

Type Mapping and Data Conversion

OData V4 has several types, which do not exist in OData V2 (e.g. `Edm.Date`, `Edm.TimeOfDay`) and the other way around `dm.DateTime`, `Edm.Time`), so we need a mapping between corresponding data types.

The following OData V2 types are supported and mapped:

- `Edm.Binary`, `Edm.Boolean`, `Edm.Byte`, `Edm.Decimal`, `Edm.Double`, `Edm.Guid`, `Edm.Int16`, `Edm.Int32`, `Edm.Int64`, `Edm.SByte`, `Edm.String` do not need a type mapping as they exist in both OData versions.
- `Edm.DateTime` is mapped to OData V4 type `Edm.Date` if the property has the OData V2 annotation `sap:display-format="date"` or otherwise to `Edm.DateTimeOffset` with UTC timezone.
- `Edm.Time` is mapped to OData V4 type `Edm.TimeOfDay`.

Some data types have different representation in OData V2 and OData V4. The application developer should only use the OData V4 values. The framework takes care that the values are converted before sending the request to the backend (e.g. as a value of a key property) and after receiving the response from the backend.

Here are some examples:

- OData V2 uses a different alphabet for the base-64 encoding for `Edm.Binary`. OData V2 uses '`+`' and '`/`' but OData V4 uses instead '`-`' and '`_`'.
- For `Edm.DateTimeOffset` OData V2 uses a JavaScript Date (i.e. `Date(1420529121547)`) and OData V4 a String (i.e. `"2015-01-06T12:25:21.547"`) representation.

Mapping of OData V4 Features

System Query Options

$expand / $select system query options

OData V4 supports "$expand with options", which means an $expand option can contain query options for the expanded navigation property such as $select, $orderby or $expand itself.. OData V2 does not support "$expand with options" but only $expand and $select with path values. An OData V4 $expand option, which contains only $select and $expand options, is transformed to the corresponding OData V2 $expand and $select options by "flattening" the OData V4 structure.

> ### Example
>
> OData V4 system query options to expand line items:
>
> ```
> $expand=SO_2_SOITEM($select=DeliveryDate,ItemPosition,SalesOrderID)
> $select=SalesOrderID,GrossAmount
> ```
>
> These options are converted into following OData V2 system query options:
>
> ```
> $expand=SO_2_SOITEM
> $select=SO_2_SOITEM/DeliveryDate,SO_2_SOITEM/ItemPosition,SO_2_SOITEM/
> SalesOrderID,SalesOrderID,GrossAmount
> ```

> **i Note**
>
> Because of the flat structure of $expand and $select, the URLs get longer than the URLs in OData V4. In some browsers that might be an issue if you use $direct as group ID. (for more information see: Batch Control [page 952]).

$orderby

OData V4 supports system query option $orderby also in $expand structures, but OData V2 supports only $orderby on top level. When consuming an OData V2 service with an OData V4 model, system query $orderby on top level is supported but an error is raised if $orderby is used in $expand.

`$orderby` can also work with expressions, but those need to be identical in V2 and V4.

$count

In OData V2 $count can only be used on top level. An error is raised if $count is used in $expand. On top level, $count is converted to V2 $inlinecount and propagated to the request.

$filter

In OData V2 $filter can only be used on top level. An error is raised if $filter is used in $expand. On top level, $filter is converted to V2 syntax and propagated to the request. $filter supports comparisons, `and`, `or`, `not` and the following built-in functions:

- String functions: `concat`, `contains` (converted to `substringof`), `endswith`, `indexof`, `length`, `startswith`, `tolower`, `toupper`, `trim`
- Date and time functions: `day`, `hour`, `minute`, `month`, `second`, `year`
- Arithmetic functions: `ceiling`, `floor`, `round`

The remaining functions are unsupported because they have no equivalent in V2.

> **⚠ Caution**
>
> Avoid passing literals to date, time and arithmetic functions, because the parameter to these functions can have different types and it cannot be decided which one is correct.
>
> > **Example**
> >
> > In floor(42) the 42 can be either an `Edm.Double` or an `Edm.Decimal`. Avoid comparing two literals like, for example `42 eq 42`, because the converter determines the type of a literal from the other operand in comparisons.

OData V2 Annotations

Following V2 (attributes with namespace http://www.sap.com/Protocols/SAPData) annotations are converted to corresponding V4 annotations (see OData V2 Model -> Meta Model for OData V2 ->Enhancement of the OData Meta Model [page 903]).

OData V2 Annotations defined at `EntitySet`:

- creatable, deletable, deletable-path, label, pageable, requires-filter, searchable, topable, updatable, updatable-path

OData V2 Annotations defined at `Property`:

- aggregation-role, creatable, creatable-path, display-format (with values `NonNegative` and `UpperCase`), field-control, filterable, filter-restriction, heading, label, precision, quickinfo, required-in-filter, sortable text, unit, updatable, visible

OData V2 Annotations defined at `Schema`:

- sap:schema-version="foo"

sap:semantics:

- bday, body, city, class, completed, country, currency-code dtend, dtstart, due, duration, familyname, fbtype, fiscalyear, fiscalyearperiode, from, givenname, honorific, location, middlename, name, nickname, note, org, org-role, org-unit, percent-complete, photo, pobox, priority, received, region, sender, status, street, subject, suffix, tel (with types `cell`, `work`, `fax`), title, transp, url, unit-of-measure, url, wholeday, year, yearmonth, yearmonthday, yearquarter, yearweek, zip

OData V2 Annotations defined at `NavigationProperty`:

- filterable, creatable, creatable-path

OData V2 Annotations defined at `FunctionImport`:

- action-for, label

Warnings are logged for all SAP attributes that have not been processed by the V2 converter.

Limitations

Not all OData V4 features are supported yet when consuming an OData V2 service. We have following limitations:

- The OData V4 model can consume an OData V2 service for read scenarios only.
- The OData V2 services has to provide inline type metadata in responses, i.e. property `__metadata.__type`. This information is needed to convert the data between the OData V2 and the OData V4 types.
- Supported data types are listed above (see Type Mapping and Data Conversion [page 978]).
- System query options $orderby, $filter and $count on top level and $expand and $select are supported. All other system query options raise an exception.
- Not all OData V2 annotations are converted yet. Supported OData V2 annotations are listed above (see OData V2 Annotations [page 979]).

> ⚠ Caution
>
> OData V4 validates that namespaces are always loaded from the same URI. Ensure to reference the metadata document (e.g. `.../IWBEP/GWSAMPLE_BASIC/$metadata`) in additional annotation files and not the service document (`.../IWBEP/GWSAMPLE_BASIC`).

Extension for Data Aggregation

The OData V4 Model supports features of the OData Extension for Data Aggregation V4.0 specification.

The binding parameter `$$aggregation` at `sap.ui.model.odata.v4.ODataModel#bindList` holds the information needed for data aggregation. It may be changed by `sap.ui.model.odata.v4.ODataListBinding#setAggregation`. It cannot be combined with an explicit system query option `$apply` because it implicitly derives `$apply`. You can find more information also in the OData Extension for Data Aggregation V4.0 specification .

Two scenarios are supported:

- You can provide properties for grouping and aggregation. An appropriate system query option `$apply` is derived from those and the list binding still provides a flat list of contexts ("rows"), but with additional aggregated properties ("columns"). In addition, you can request grand total values for aggregatable properties. In this case, an extra row appears at the beginning of the flat list of contexts and contains the grand total values as well as empty values for all other properties.

  ### Sample Code

  Example XML View With Grand Total

```
<table:Table fixedRowCount="1"
 rows="{
  path : '/BusinessPartners',
  parameters : {
   $$aggregation : {
    aggregate : {
     SalesAmountSum  : {
      grandTotal : true,
      name : 'SalesAmount',
      with : 'sap.unit_sum'
     }
    },
    group : {
     Region : {}
    }
   },
   $count : true,
   $filter : 'SalesAmountSum gt 1000000',
   $orderby : 'SalesAmountSum desc'
  }}">
 <table:Column template="Region">
  <Label text="Region"/>
 </table:Column>
 <table:Column hAlign="End">
  <Label text="Sales Amount"/>
  <table:template>
   <Text text="{path : 'SalesAmountSum', type :
'sap.ui.model.odata.type.Decimal'}" />
  </table:template>
 </table:Column>
 <table:Column>
  <Label text="Currency"/>
  <table:template>
   <Text text="{path : 'SalesAmountSum@Analytics.AggregatedAmountCurrency',
    type : 'sap.ui.model.odata.type.String'}" />
  </table:template>
 </table:Column>
</table:Table>
```

- You can provide group levels to determine a hierarchy of expandable group levels in addition to the leaf nodes determined by the `groupable` and `aggregatable` properties. Only a **single** group level is currently supported and it cannot be expanded yet. Group levels cannot be combined with filtering or with the system query option `$count : true`.

> **! Restriction**
>
> Multi-unit situations are not supported with data aggregation. An error is thrown if the `sap.ui.model.odata.v4.ODataListBinding` detects a multi-unit situation.
>
> Given a service with groupable properties `G1, ..., Gn`, an aggregatable property `A` with related unit property `U`. An aggregated OData request is said to return a multi-unit situation, if the following conditions are fulfilled for the requested aggregation levels `G1, ..., Gj` :
>
> 1. The result contains two or more entities with identical values for the groupable properties `G1, ..., Gj`.
> 2. The entities from **1.** have **different** values for the unit-property `U` and any value for `A`.

> **! Restriction**
>
> The grand total calculation is currently only supported for the standard aggregation functions `sum`, `min`, and `max` as well as for custom aggregates that use these functions. This also applies to displaying subtotals of group levels.

Filtering

Filters are provided to the list binding as described in Filtering [page 939]. The `Filter` objects are analyzed automatically to perform the filtering before the aggregation where possible using the `filter()` transformation. The remaining filters, including the provided `$filter` parameter of the binding, are applied after the aggregation either via the system query option `$filter` or within the system query option `$apply`, using again the `filter()` transformation.

Server Messages in OData V4 Model

The OData V4 model supports server messages sent via an OData V4 service.

> **⚠ Caution**
>
> This feature is experimental. For more information, see Compatibility Rules [page 17].

Messages transported via an OData V4 service response are parsed and reported to the message model `sap.ui.model.message.MessageModel`. An application can retrieve the messages and display them in a suitable control, for example in `sap.m.MessageView`.

End user messages contain the following information:

- `code` - language-independent message code

- `message`- language-dependent message text
- `target` - path to the target of the message detail
- `technicalDetails` - technical details of the message
- `transition` - specifies a message as a state (false) or a transition message (true)
- `numericSeverity` – classification of end user messages; allowed values: 1 (success), 2 (info), 3 (warning), 4 (error); `numericSeverity` is mapped to the specific `sap.ui.core.MessageType`
- `longtextUrl` – optional; is omitted, if there is no long text available for the corresponding message.

The use of the fields in specific cases is described in the sections below.

Messages can be either bound or unbound: Unbound messages are not related to OData entities and are, therefore, also not part of the OData success response in the HTTP body. Bound messages are related to OData entities and are modeled as OData resources.

Unbound Messages

Unbound messages are transported in the header field `sap-messages`, which is an array of messages. Unbound messages cannot be suppressed. They are always returned by the server and they always refer to the current request as described in the section about transition messages below. In case of successful requests, unbound messages are transported as an array in the HTTP header field `sap-messages`:

```
sap-messages:[
     {
          "code" : "SYS/42",
          "message" : "System will be down for maintenance next weekend.",
          "numericSeverity" : 2,
          "longtextUrl" : "Messages(3)/LongText/$value"
     }
]
```

Note

`longtextUrl` can be a relative or absolute path. Relative paths are treated as relative to the request URL. Absolute paths are treated as relative to the server.

Example

Request URL: `http://<server>:<port>/serviceroot.svc/BusinessPartners(42)/to_Address; longtextUrl: "Messages(3)/LongText/$value"`

Result: `http://<server>:<port>/serviceroot.svc/BusinessPartners(42)/Messages(3)/LongText/$value`

Request URL: `http://<server>:<port>/serviceroot.svc/BusinessPartners(42); longtextUrl: "/Messages(3)/LongText/$value"`

Result: `http://<server>:<port>/Messages(3)/LongText/$value`

Bound Messages

Bound messages are related to OData entities and are modeled as OData resources. An OData entity contains its bound messages as collection valued property of the complex type specified in the description of `com.sap.vocabularies.Common.v1.Messages`. Thus, bound messages are transported in the HTTP body. The target property specifies to which property the message is bound. The application needs to specify in the `$select` binding parameter whether messages should be returned by the server, or not.

```
<ComplexType Name="<name of message type>">
    <Property Name="code" Type="Edm.String" Nullable="false" />
    <Property Name="message" Type="Edm.String" Nullable="false" />
    <Property Name="target" Type="Edm.String" Nullable="true" />
    <Property Name="transition" Type="Edm.Boolean" Nullable="false" />
    <Property Name="numericSeverity" Type="Edm.Byte" Nullable="false" />
    <Property Name="longtextUrl" Type="Edm.String" Nullable="true" />
</ComplexType>
```

The `target` property may contain a path relative to the entity which contains the message. The target can, for example, refer to a property within that entity. This information is used to highlight UI elements such as input fields, if they are bound to properties referenced by the path contained in the `target` property. All responses are checked for bound messages. If there are messages, they are reported to the message model.

For bound messages, `longtextUrl` can be a relative or absolute path. Relative paths are treated as relative to the innermost context path (`@odata.context`) in the response, or to the request URL, if there is no context path. Absolute paths are treated as relative to the server.

Messages in Error Responses

Error messages are always reported in the error response in JSON format as described in the OData JSON Format Version 4.0 in section *19 Error Response* with the following additions:

- The instance annotation `com.sap.vocabularies.Common.v1.longtextUrl` can be used to provide a long text URL, which can be a relative or an absolute path. Relative paths are treated as relative to the request URL. Absolute paths are treated as relative to the server.
- `target` is relative to the requested resource.
- The error message type is always `sap.ui.core.MessageType.Error`. The instance annotation `com.sap.vocabularies.Common.v1.numericSeverity` determines the message type of the detail messages.
- The error message and all messages in details are transition messages.

State Messages and Transition Messages

Messages can be either state or transition messages:

- State messages refer to the state of the corresponding resource (OData entity instance). State messages are valid as long as the related business object is not changed. The OData V4 Model is responsible for the lifecycle of state messages and will remove state messages from the message model, if they are no longer sent by the server when the corresponding resource is requested.

- Transition messages refer to the current request and are not related to the state of a resource. They are only relevant for the request that was triggered, for example *System not available, business object could not be updated*. Optionally, transition messages can reference a business object, for example *Shipping address could not be changed due to missing authorization*. Transition messages are translated into persistent messages in the message model. The application is responsible for the lifecycle of such persistent messages. The OData V4 Model will not remove persistent messages from the message model.

Lifecycle Management for State Messages

The lifecycle management for state messages is optimized for a specific orchestration with the server. When bound messages are requested, the OData V4 server returns all bound messages for the respective entity and its subentities within the same business object. The business object is defined by the first path segment.

The following example uses a sales order with items and related products:

- A `GET` request for `/SalesOrder(´0815´)` returns all bound messages for the sales order and the items, even if the items themselves are not contained in the response. Messages to assigned products, business partners, and so on, that are not part of the `SalesOrder` business object will **not** be sent if the path starts within the `SalesOrder` business object.
- A `GET` request for a specific item with path `/SalesOrder(´0815´)/_Items(´010´)` returns all bound messages for this item.
- A `GET` request for the product related to an item using the deep path `/SalesOrder(´0815´)/_Items(´010´)/_Product` will not return any bound messages.

The OData V4 model checks whether the response contains the message property and removes all previous bound state messages from the message model, if their target path starts with the path of the entity.

This concept has the following consequences:

- When you display the information for the business object itself, you can also display the messages for all subentities of this business object.
- For displaying the entities within a business object, an application has to use deep paths, instead of canonical paths. Otherwise, messages will appear twice. In the object page of item `´010´`, for example, the binding needs to use the path `/SalesOrder(´0815´)/_Items(´010´)`. You can achieve this also with a relative binding using the context of the sales order.
- Binding entities outside the business object with the deep path means that no messages will be retrieved for this entity. Using the binding `/SalesOrder(´0815´)/_Items(´010´)/_Product` to display product information of item `010`, for example, will not return any product-specific bound message.
- As a consequence, it must also **not** be possible to change the entity that is bound with a path that starts with a different business object. If, for example, product information needs to be changed, we recommended to use the canonical path to bind the product assigned to item `010` to achieve that the server sends the bound messages of the product.

> **i Note**
>
> The SAPUI5 V4 ODataModel is agnostic to business objects. The application needs to take care of the proper setup.

Combining State/Transition and Bound/Unbound Messages

	State	Transition
Unbound	✗	✓
Bound	✓	✓

Message Severity

The table shows the supported severity values and their mapping to the specific `sap.ui.core.MessageType`.

numericSeverity	Type	Comment
1	`sap.ui.core.MessageType.Success`	Positive feedback - no action required
2	`sap.ui.core.MessageType.Information`	Additional information - no action required
3	`sap.ui.core.MessageType.Warning`	Warning - action may be required
4	`sap.ui.core.MessageType.Error`	Error - action is required

Accessing the Original Message

The attribute `technicalDetails.originalMessage` of the message in the message model allows you to access the original message from the back-end.

Currencies and Units

> ⚠ Caution
>
> This feature is experimental. For more information, see Compatibility Rules [page 17].

For amounts or measures, you may sometimes need different currencies or units than defined in the CLDR. The data types `sap.ui.model.odata.type.Currency` and `sap.ui.model.odata.type.Unit` enable you to use code lists with customizing for currency codes and units. For code lists with customizing, you need to define the following annotations:

- Currencies: `com.sap.vocabularies.CodeList.v1.CurrencyCodes`
- Measures: `com.sap.vocabularies.CodeList.v1.UnitsOfMeasure`

Code list annotations for currency codes and measures in "metadata.xml"

```
<EntityType Name="Product">
    ...
   <Property Name="WeightMeasure" Type="Edm.Decimal" Nullable="false"
Precision="13" Scale="variable" />
   <Property Name="WeightUnit" Type="Edm.String" Nullable="false"
MaxLength="3" />
   <Property Name="CurrencyCode" Type="Edm.String" Nullable="false"
MaxLength="5" />
   <Property Name="Price" Type="Edm.Decimal" Nullable="false" Precision="15"
Scale="variable" />
    ...
</EntityType>
...
<Annotations Target="SAP__self.Container">
   <Annotation Term="com.sap.vocabularies.CodeList.v1.CurrencyCodes">
      <Record>
         <PropertyValue Property="Url" String="../../../../default/iwbep/common/
0001/$metadata" />
         <PropertyValue Property="CollectionPath" String="Currencies" />
      </Record>
   </Annotation>
</Annotations>
<Annotations Target="SAP__self.Container">
   <Annotation Term="com.sap.vocabularies.CodeList.v1.UnitsOfMeasure">
      <Record>
         <PropertyValue Property="Url" String="../../../../default/iwbep/common/
0001/$metadata" />
         <PropertyValue Property="CollectionPath" String="UnitsOfMeasure" />
      </Record>
   </Annotation>
</Annotations>

...
<Annotations Target="SAP__self.Product/Price">
    ...
   <Annotation Term="Org.OData.Measures.V1.ISOCurrency" Path="CurrencyCode" />
    ...
</Annotations>
...
<Annotations Target="SAP__self.Product/WeightMeasure">
    ...
   <Annotation Term="Org.OData.Measures.V1.Unit" Path="WeightUnit" />
    ...
</Annotations>
```

Code lists that are referenced by the `com.sap.vocabularies.CodeList.v1.CurrencyCodes` or `com.sap.vocabularies.CodeList.v1.UnitsOfMeasure` annotations need the following:

- The internal code as its only key property
- A language-dependent description
- A numeric property with the unit-specific number of significant fractional digits
- Optional: An external code that should be visualized instead of the internal code
- Optional: A standard code

The key property is annotated with:

- `com.sap.vocabularies.Common.v1.Text` pointing to the description property
- `com.sap.vocabularies.Common.v1.UnitSpecificScale` pointing to the numeric property
- Optional: `com.sap.vocabularies.CodeList.v1.StandardCode` pointing to the standard code property

The entity type is optionally annotated with `Org.OData.Core.V1.AlternateKeys` pointing to another property that should be used for visualization.

If the alternate key is available, the type uses the alternate key as the key of the currency or unit. In this case, the data of the actual service have to contain the alternate key representation in the currency or unit property. The key is used and expected in the data if no alternate key is annotated. Note that there must be a maximum of one alternate key, and that key and alternate key must have exactly one property.

The property annotated as `com.sap.vocabularies.CodeList.v1.StandardCode` is interpreted as the ISO code by `sap.ui.model.odata.type.Currency` and used to find currency symbols. The currency symbols may be used for entering data.

Example for the metadata of a code list service

```
...
  <EntityType Name="Currency">
    <Key>
      <PropertyRef Name="CurrencyCode" />
    </Key>
    <Property Name="CurrencyCode" Type="Edm.String" MaxLength="5" />
    <Property Name="ISOCode" Type="Edm.String" MaxLength="3" />
    <Property Name="Text" Type="Edm.String" MaxLength="15" />
    <Property Name="DecimalPlaces" Type="Edm.SByte" />
  </EntityType>

  <EntityType Name="UnitOfMeasure">
    <Key>
      <PropertyRef Name="UnitCode" />
    </Key>
    <Property Name="UnitCode" Type="Edm.String" MaxLength="3" />
    <Property Name="ISOCode" Type="Edm.String" MaxLength="3" />
    <Property Name="ExternalCode" Type="Edm.String" MaxLength="3" />
    <Property Name="Text" Type="Edm.String" MaxLength="30" />
    <Property Name="DecimalPlaces" Type="Edm.Int16" />
  </EntityType>

  <Annotations Target="SAP__self.Currency/CurrencyCode">
    <Annotation Term="Common.Text" Path="Text" />
    <Annotation Term="Common.UnitSpecificScale" Path="DecimalPlaces" />
    <Annotation Term="CodeList.StandardCode" Path="ISOCode" />
  </Annotations>

  <Annotations Target="SAP__self.UnitOfMeasure">
    <Annotation Term="Core.AlternateKeys">
      <Collection>
        <Record>
          <PropertyValue Property="Key">
            <Collection>
              <Record>
                <PropertyValue Property="Name" PropertyPath="ExternalCode" />
                <PropertyValue Property="Alias" String="ExternalCode" />
              <Record>
            </Collection>
          </PropertyValue>
        <Record>
      </Collection>
```

```
    </Annotation>
  </Annotations>

  <Annotations Target="SAP__self.UnitOfMeasure/UnitCode">
    <Annotation Term="Common.Text" Path="Text" />
    <Annotation Term="Common.UnitSpecificScale" Path="DecimalPlaces" />
    <Annotation Term="CodeList.StandardCode" PropertyPath="ISOCode" />
    <Annotation Term="CodeList.ExternalCode" PropertyPath="ExternalCode" />
  </Annotations>
...
```

With the metadata above, you can use the data types `sap.ui.model.odata.type.Currency` and the `sap.ui.model.odata.type.Unit` in an input field as shown in the following example. The data types use a complex binding with the amount or measure as first part, the currency code or unit as second part, and the information about the code list customizing that has to be used as third part.

Example how to use currency and unit types in a freestyle application

```
...
<Input value="{mode:'TwoWay', parts:['WeightMeasure', 'WeightUnit',
{mode:'OneTime', path:'/##@@requestUnitsOfMeasure', targetType:'any'}],
type:'sap.ui.model.odata.type.Unit'}"/>
...
<Input value="{mode:'TwoWay', parts:['Price', 'CurrencyCode', {mode:'OneTime',
path:'/##@@requestCurrencyCodes', targetType:'any'}],
type:'sap.ui.model.odata.type.Currency'}"/>
...
```

The code lists are automatically requested only once per browser session and code list URL.

If you use XML templating, you can use `sap.ui.model.odata.v4.AnnotationHelper.format` to generate the composite binding for an amount or measure property. To recognize a property as an amount or measure, the property needs to be annotated either with the `Org.OData.Measures.V1.ISOCurrency`, or with the `Org.OData.Measures.V1.Unit` annotation. For more informatio about XML templating, see XML Templating [page 1018].

Additional annotations when using XML templating

```
<!-- used in view template -->
<Annotations Target="SAP__self.Product">
   <Annotation Term="com.sap.vocabularies.UI.v1.LineItem">
      <Collection>
         ...
         <Record Type="com.sap.vocabularies.UI.v1.DataField">
            <PropertyValue Property="Label" String="Weight" />
            <PropertyValue Property="Value" Path="WeightMeasure" />
         </Record>
         <Record Type="com.sap.vocabularies.UI.v1.DataField">
            <PropertyValue Property="Label" String="Price" />
            <PropertyValue Property="Value" Path="Price" />
         </Record>
         ...
      </Collection>
   </Annotation>
</Annotations>
```

You can now use `sap.ui.model.odata.v4.AnnotationHelper.format` in the XML template view to generate the composite binding for `sap.ui.model.odata.type.Currency` and `sap.ui.model.odata.type.Unit types`.

How to use `AnnotationHelper.format` with currencies or units

```
<template:alias name="format"
value="sap.ui.model.odata.v4.AnnotationHelper.format">
<template:alias name="label"
value="sap.ui.model.odata.v4.AnnotationHelper.label">
<VBox>
   <template:with path="meta>/ProductList/@com.sap.vocabularies.UI.v1.LineItem"
var="lineItem">
      <Table items="{/ProductList}">
         <columns>
            <template:repeat list="{lineItem>}" var="field">
               <Column>
                  <Label text="{field>@@label}"/>
               </Column>
            </template:repeat>
         </columns>
         <ColumnListItem>
            <template:repeat list="{lineItem>}" var="field">
               <Input value="{field>Value/@@format}"/>
            </template:repeat>
         </ColumnListItem>
      </Table>
   </template:with>
</VBox>
</template:alias>
</template:alias>
```

Example: Templating output

```
<VBox>
    <Table items="{/ProductList}">
      <columns>
          ...
          <Column>
            <Label text="Weight"/>
          </Column>
          <Column>
            <Label text="Price"/>
          </Column>
          ...
      </columns>
      <ColumnListItem>
              ...
              <Input value="{mode:'TwoWay', parts:[{path:'WeightMeasure',
type:'sap.ui.model.odata.type.Decimal', constraints:{'precision':13,
'scale':'variable', 'nullable':false}}, {path:'WeightUnit',
type:'sap.ui.model.odata.type.String', constraints:{'maxLength':3,
'nullable':false}}, {mode:'OneTime', path:'/##@@requestUnitsOfMeasure',
targetType:'any'}], type:'sap.ui.model.odata.type.Unit'}"/>
              <Input value="{mode:'TwoWay', parts:[{path:'Price',
type:'sap.ui.model.odata.type.Decimal', constraints:{'precision':15,
'scale':'variable', 'nullable':false}}, {path:'CurrencyCode',
type:'sap.ui.model.odata.type.String', constraints:{'maxLength':5,
'nullable':false}}, {mode:'OneTime', path:'/##@@requestCurrencyCodes',
targetType:'any'}], type:'sap.ui.model.odata.type.Currency'}"/>
              ...
      </ColumnListItem>
    </Table>
</VBox>
```

JSON Model

The JSON model can be used to bind controls to JavaScript object data, which is usually serialized in the JSON format.

The JSON model is a client-side model and, therefore, intended for small data sets, which are completely available on the client. The JSON model does **not** support mechanisms for server-based paging or loading of deltas. It supports, however, two-way binding. Also, client-side models like the JSON model have **no** built-in support for sending data back to the server. The apps have to use, for example, `model.getData()` and `jQuery.ajax()` to send updated data to the server.

To instantiate a JSON model, use the following code:

```
var oModel = new sap.ui.model.json.JSONModel();
```

After the instance has been created, there are different options to get the data into the model.

The easiest option is to set data by using the `setData` method:

```
oModel.setData({
    firstName: "Peter",
    lastName: "Pan"
});
```

> **i** Note
>
> The correct JSON notation uses double quotes for the keys and string values.

Usually, you do not define your data inline in the application but load it from a server-side service using an XHR request. The JSON model, however, also has a `loadData` method, which loads the JSON data from the specified URL asynchronously and applies it to the model:

```
oModel.loadData("data.json");
```

Related Information

API Reference: `sap.ui.model.json.JSONModel`

Sorting and Filtering in JSON Models

If you use a JSON model for data binding, sorting and filtering is implemented in JavaScript because the data is available on the client. You can use custom sorting and filtering methods in the JSON model. To define custom

methods, set the `fnCompare` method on the Sorter object or the `fnTest` method on the filter object after creating it.

The `fnTest` method of the filter gets the value to test as the only parameter and returns, whether the row with the given value should be filtered or not.

```
var oFilter = new sap.ui.model.Filter("property", function(value) {
    return (value > 100);
});
```

The `fnCompare` method of the Sorter gets the two values to compare as parameters and returns -1, 0 or 1, dependent on which of the two values should be ordered before the other:

```
var oSorter = new sap.ui.model.Sorter("property");
oSorter.fnCompare = function(value1, value2) {
    if (value1 < value2) return -1;
    if (value1 == value2) return 0;
    if (value1 > value2) return 1;
};
```

Binding Path Syntax for JSON Models

The JSON model has a simple binding path syntax, because it consists of named objects, such as properties, arrays, or nested objects.

The following example shows a simple JSON model with the different binding paths:

```
{
    company: {
        name: "Treefish Inc",
        info: {
            employees: 3,
        },
        contacts: [
            {
                name: "Barbara",
                phone: "873"
            },
            {
                name: "Gerry",
                phone: "734"
            },
            {
                name: "Susan",
                phone: "275"
            }
        ]
    }
}
```

Absolute binding paths within this model:

```
/company/name
/company/info/employees
/company/contacts
```

Relative binding paths within the "/company" context:

```
name
info/employees
contacts
```

Relative binding paths within a list binding of "/company/contacts":

```
name
phone
```

XML Model

The XML model allows to bind controls to XML data. It is a client-side model intended for small datasets, which are completely available on the client. The XML model does not contain mechanisms for server-based paging or loading of deltas. It supports two-way binding.

To instantiate the model, use the following code:

```
var oModel = new sap.ui.model.xml.XMLModel();
```

The XML model allows to bind controls to XML data. It is a client-side model intended for small data sets, which are completely available on the client. The XML model does not contain mechanisms for server-based paging or loading of deltas. It supports two-way binding.

```
oModel.setData(oXMLDocument);
```

To create inline XML data or to get XML data as a string, the XML model provides a `setXML` method. This method takes XML in text format and uses the browser's XML parser to create a document.

```
oModel.setXML("<?xml version=\"1.0\"?><some><xml>data</xml></some>");
```

Usually, you load your data from the server using an HTTP-based service, so the `loadData` method provides an easy way to load XML data from the given URL:

```
oModel.loadData("data.xml");
```

For more information, see the API Reference in the Demo Kit.

Related Information

API Reference: `sap.ui.model.xml.XMLModel`

Sorting and Filtering in XML Models

If you use an XML model for data binding, sorting and filtering is implemented in JavaScript because all data is available on the client. You can use custom methods for sorting and filtering in an XML model. To define

custom methods, set the `fnCompare` method on the Sorter object or the `fnTest` method on the Filter object after creating it.

The `fnTest` method of the Filter gets the value to test as the only parameter and returns, whether the row with the given value should be filtered or not. To implement a filter, use the following code :

```
var oFilter = new sap.ui.model.Filter("property");
oFilter.fnFilter = function(value) {
    return (value > 100);
};
```

The `fnCompare` method of the Sorter gets the two values to compare as parameters and returns -1, 0 or 1, dependent which of the two values should be ordered before the other. To implement a sorter, use the following code:

```
var oSorter = new sap.ui.model.Sorter("property");
oSorter.fnCompare = function(value1, value2) {
    if (value1 < value2) return -1;
    if (value1 == value2) return 0;
    if (value1 > value2) return 1;
};
```

XML Namespace Support

The XML model supports documents using XML namespaces.

For this purpose, you must declare namespaces using the `setNameSpace` method. The namespace prefixes do not necessarily need to be the same as in the XML document, they only used in the binding paths which are used to address nodes in the document.

Assumed this sample XML document:

```
<data xmlns="http://tempuri.org/base" xmlns:ext="http://tempuri.org/ext">
     <ext:entry id="0" value="foo" />
     <ext:entry id="1" value="foo" />
</data>
```

The namespaces must be declared in the JavaScript like this, to be able to bind to them:

```
var oModel = new sap.ui.model.xml.XMLModel(oXMLDoc);
oModel.setNameSpace("http://tempuri.org/base");
oModel.setNameSpace("http://tempuri.org/ext", "e"); [...]
oTable.bindRows("/e:entry");
```

Binding Path Syntax for XML Models

XML models differentiate between attributes and content. XML has no arrays and defines lists as multiple elements with the same name instead. This makes the binding path syntax for XML models more difficult than for JSON or OData models.

For attributes, a special selector using the "@" character exists and "text()" can be used to reference the content text of an element. Lists are referenced by using the path to the multiple element.

> **i** Note
>
> For the XML model the root must **not** be included in the path.

```
<companies>
  <company name="Treefish Inc">
    <info>
       <employees>3</employees>
    </info>
    <contact phone="873">Barbara</contact>
    <contact phone="734">Gerry</contact>
    <contact phone="275">Susan</contact>
  </company>
</companies>
```

Absolute binding paths within this model:

```
/company/@name
/company/info/employees
```

Relative binding paths within the `/company` context:

```
@name
info/employees/text()
```

Relative binding paths within a list binding of `/company/contact`:

```
text()
@phone
```

> **i** Note
>
> In a similar JSON model you would use `/companies/company/locations` as binding path for the `locations` collection. In an XML model the respective collection binding path is: `/company/locations/location`.

Resource Model

The resource model is used as a wrapper for resource bundles. In data binding you use the resource model instance, for example, to bind texts of a control to language-dependent resource bundle properties.

A resource model is instantiated with a `bundleName` or a `bundleURL`. The bundle name is the name of the resource bundle and equals a SAPUI5 module name within the define/require concept. The bundle URL points

to a resource bundle. If you use the bundle name, the file must have the `.properties` suffix. If you do not specify a `locale`, the system uses the login language: `var oModel = new sap.ui.model.resource.ResourceModel({bundleName:"myBundle",locale:"en"});`

In this resource model implementation you cannot pass parameters to your texts within the resource bundle. If you have to pass parameters, you must do this on your own. Therefore, you can load the bundle yourself or retrieve it from the model.

```
var myBundle = oModel.getResourceBundle();
```

After the resource model has been instantiated, you have a model containing the resource bundle texts as data.

API Reference: `sap.ui.model.resource.ResourceModel`

Binding Path Syntax for Resource Models

The binding path syntax for the resource model only contains a flat list of properties.

The following example shows a simple resource model that illustrates the possible binding paths: Resource bundle content:

```
CLOSE_BUTTON_TEXT=Close
OPEN_BUTTON_TEXT=Open
```

```
CANCEL_BUTTON_TEXT=Cancel
```

Binding paths within the model:

```
CLOSE_BUTTON_TEXT
OPEN_BUTTON_TEXT
CANCEL_BUTTON_TEXT
```

Binding Texts to a Resource Bundle

If you don't want to use a component or descriptor file, or you want to use a more fine-grained resource bundle, you can declaratively instantiate a resource model in an XML or JSON view. To do so, you define the resource bundle by a name (`resourceBundleName` property) or a URL (`resourceBundleUrl` property) and assign an alias (`resourceBundleAlias` property) for the bundle in the view definition.

The `ResourceModel` required for binding these texts is created during view instantiation. The model is set as secondary model with the given alias to the view instance. If you want to bind other properties to another model, you have to create the model on your own in the corresponding controller or HTML page and attach it to the view with another alias. The binding itself behaves in the same way as every SAPUI5 data binding and as described above.

1. Define the following resource bundle content: `MY_TEXT=Hello World`
2. To bind this resource bundle content in XML views, insert the following code:

```
<core:View resourceBundleName="myBundle"
           resourceBundleAlias="i18n"
           controllerName="sap.hcm.Address" xmlns="sap.m"
xmlns:core="sap.ui.core"
           xmlns:html="http://www.w3.org/1999/xhtml">
   <Panel>
      <Button text="{i18n>MY_TEXT}"/>
   </Panel>
<core:View>
```

Custom Model

Custom models can be used if none of the models provided by SAPUI5 is suitable for the specific needs of an application.

To instantiate a custom model, proceed as follows:

1. Extend the `Model` class and specify the binding modes that the model should support (for example, two-way, one-way, one-time).
2. Extend the `Binding` class to suit your specific binding or reuse the existing specific binding implementations `PropertyBinding`, `ListBinding`, and/or `TreeBinding`.
3. To enable the filtering functionality, use the `Filter` class with `FilterOperator` enum in your binding implementation.
4. To enable the sorting functionality, use the `Sorter` class in your binding implementation.

You can find all necessary classes in the `sap.ui.model` namespace. As a starting point, take a look at the `JSONModel` implementation in `sap.ui.model.json.JSONModel`.

Assigning the Model to the UI

If you don't want to use a component or descriptor file, you have to assign the model instance manually to the UI, before you can bind controls to this model instance.

SAPUI5 provides a flexible and modularized concept in which you can not only define one model for your applications, but define different areas in your application with different models and assign single controls to a model. You can, for example, define a JSON model for the application and an OData model for a table contol that is contained in the application. You can also set multiple models for a control, a UI area, or the core by specifying a name for the model. These models can be accessed by their name.

```
var oJSONModel = new sap.ui.model.json.JSONModel();
var oODataModel  = new sap.ui.model.odata.v2.ODataModel("myServicelUrl");
var oControl  = new sap.m.Input();
oControl.setModel(oODataModel);
//set the JSONModel with the name 'myJSONModel' to the same control
oControl.setModel(oJSONModel,"myJSONModel");
```

When you set a model to a UI area or control, it will be propagated to all aggregated child controls. So if you set a model to a container control, for example, all controls that are contained (aggregated) in this container have access to this model. If one of the contained controls has its own model set (with the same name), the propagation stops. It is not possible to have two models with the same name set to one control instance.

Choose one of the following options:

- You can define a global model that can be accessed by all controls from all UI areas by using the `setModel` method on the SAPUI5 core object. This is useful for simple form applications or demo applications.

  ```
  sap.ui.getCore().setModel(oModel);
  ```

- You can also define a specific model for sections within a UI area, for example, inside a panel or for a table control. In this case, you can use the `setModel` method available on any control:

  ```
  var oTable = sap.ui.getCore().byId("table");
  oTable.setModel(oModel);
  ```

Related Information

Components [page 720]
Descriptor for Applications, Components, and Libraries [page 734]

Setting the Default Binding Mode

The default binding mode applies when a model instance is created. You can overwrite the default binding mode after model creation.

- To change the default binding mode, call the `setDefaultBindingMode` method on the model as follows:

  ```
  var oModel = new sap.ui.model.json.JSONModel();
  oModel.setDefaultBindingMode(sap.ui.model.BindingMode.OneWay);
  ```

  In this example, all new bindings for the model will have the one-way binding mode by default.
- You can, however, only set supported binding modes as default binding mode. You can check if a binding mode is supported as follows:

  ```
  var oModel = new sap.ui.model.json.JSONModel();
  if (oModel.isBindingModeSupported(sap.ui.model.BindingMode.OneTime)) { // true
      oModel.setDefaultBindingMode(sap.ui.model.BindingMode.OneTime);
  }
  ```

  > **i** Note
  >
  > When you change the binding mode of an existing model instance, the existing bindings are not updated with the newly set binding mode.

Using Data Binding for Data Export

Data binding supports the export of data in a specific format so that the data can be used in other programs.

To export data, load the necessary modules as shown in the following example:

```
sap.ui.require(["sap/ui/core/util/Export", "sap/ui/core/util/ExportTypeCSV"],
function(Export, ExportTypeCSV) {
    // ...
});
```

The following code snippet uses a JSON model as basis for the export. You can also use other models, such as the OData model.

```
// "JSONModel" required from module "sap/ui/model/json/JSONModel"
var oModel = JSONModel([
    {
        firstname: "Al",
        lastname: "Dente"
    },
    {
        firstname: "Andy",
        lastname: "Friese"
    },
    {
        firstname: "Anita",
        lastname: "Mann"
    },
    {
        firstname: "Doris",
        lastname: "Schutt"
    },
```

```
    {
        firstname: "Kenya",
        lastname: "Dewit"
    }
]);
```

In the next step, create the data export object and pass the required information for the export to the object:

```
// "Export" required from module "sap/ui/core/util/Export"
var oExport = new Export({
    // "ExportTypeCSV" required from module "sap/ui/core/util/ExportTypeCSV"
    // Type that will be used to generate the content. Own ExportType's can be
created to support other formats
    exportType: new ExportTypeCSV({
        separatorChar: ";"
    }),
    // Pass in the model created above
    models: oModel,
    // binding information for the rows aggregation
    rows: {
        path: "/"
    },
    // column definitions with column name and binding info for the content
    columns: [
        {
            name: "First name",
            template: {
                content: {
                    path: "firstname"
                }
            }
        },
        {
            name: "Last name",
            template: {
                content: {
                    path: "lastname"
                }
            }
        }
    ]
});
```

The export class provides a generate method that triggers the generation process and returns a jQuery Promise object. The done handler is called when the generation process has finished. If you use the OData model, this happens asynchronously. The always handler is also called when the generation has failed. When the generation has finished and the export object is no longer needed, destroy the export object.

```
oExport.generate().done(function(sContent) {
    console.log(sContent);
}).always(function() {
    this.destroy();
});
```

The above example provides the following output:

```
First name;Last name
Al;Dente
Andy;Friese
Anita;Mann
Doris;Schutt
Kenya;Dewit
```

You can directly save the file by triggering a download. This calls the generate method internally and uses the file util class (`sap/ui/core/util/File`) to trigger the download.

```
oExport.saveFile().always(function() {
    this.destroy();
});
```

Export Types

You can use the CSV export type out of the box, or define other export types. The concept is similar to custom notepad controls, see Developing Controls [page 2158]. The generate method is called and should return the created file as a string.

> **i Note**
>
> Make sure that all values are encoded or escaped properly.

```
// "ExportType" required from module "sap/ui/core/util/ExportType"
// "encodeXML" required from module "sap/base/security/encodeXML"
ExportType.extend("my.own.ExportType", {
    init: function() {
        // Set default values
        this.setProperty("fileExtension", "mytype", true);
        this.setProperty("mimeType", "text/mytype", true);
        this.setProperty("charset", "utf-8", true);
    },
    generate: function() {
        var aBuffer = [];
        var oColumns = this.columnGenerator(),
            oColumn;
        aBuffer.push("<columns>");
        while (!(oColumn = oColumns.next()).done) {
            aBuffer.push("<column>" + encodeXML(oColumn.value.name) + "</
column>");
        }
        aBuffer.push("</columns>");

        var oRows = this.rowGenerator(),
            oRow;
        aBuffer.push("<rows>");
        while (!(oRow = oRows.next()).done) {
            var oCells = oRow.value.cells,
                oCell;
            aBuffer.push("<row>");
            aBuffer.push("<cells>");
            while (!(oCell = oCells.next()).done) {
                aBuffer.push("<cell");
                if (oCell.value.customData.color) {
                    aBuffer.push(" color=\"" +
encodeXML(oCell.value.customData.color) + "\"");
                }
                aBuffer.push(">");
                aBuffer.push(encodeXML(oCell.value.content));
                aBuffer.push("</cell>");
            }

        aBuffer.push("</rows>");

        return aBuffer.join("");
    }
```

```
});
```

Custom Data

It is also possible to pass `customData` to the cell template. This can be used to provide additional metadata to the `ExportType` (see example code above).

```
// column definitions with column name, binding info for the content and
additional custom data
columns: [
    {
        name: "First name",
        template: {
            content: {
                path: "firstname"
            },
            customData: [
                {
                    "key": "color",
                    "value": {
                        path: "color"
                    }
                }
            ]
        }
    },
    {
        name: "Last name",
        template: {
            content: {
                path: "lastname"
            }
        }
    }
]
```

Model Data

```
// "JSONModel" required from module "sap/ui/model/json/JSONModel"
var oModel = new JSONModel([
    {
        firstname: "Al",
        lastname: "Dente",
        color: "red"
    },
    {
        firstname: "Andy",
        lastname: "Friese",
        color: "black"
    },
    {
        firstname: "Anita",
        lastname: "Mann",
        color: "yellow"
    },
    {
        firstname: "Doris",
        lastname: "Schutt",
        color: "green"
    },
    {
        firstname: "Kenya",
        lastname: "Dewit",
        color: "blue"
    }
]);
```

Output

```
<columns>
    <column>First name</column>
    <column>Last name</column>
</columns>
<rows>
    <row>
        <cells>
            <cell color="red">Al</cell>
            <cell>Dente</cell>
        </cells>
    </row>
    <row>
        <cells>
            <cell color="black">Andy</cell>
            <cell>Friese</cell>
        </cells>
    </row>
    <row>
        <cells>
            <cell color="yellow">Anita</cell>
            <cell>Mann</cell>
        </cells>
    </row>
    <row>
        <cells>
            <cell color="green">Doris</cell>
            <cell>Schutt</cell>
        </cells>
    </row>
    <row>
        <cells>
            <cell color="blue">Kenya</cell>
            <cell>Dewit</cell>
        </cells>
    </row>
</rows>
```

Integration in Controls

`sap/ui/table/Table`

The `exportData` method creates an export instance and fills the rows and columns with the table's rows/column definition, if not defined otherwise. This also includes filters and sorters that have been applied to the columns.

```
// "ExportTypeCSV" required from module "sap/ui/core/util/ExportTypeCSV"
oTable.exportData({
    exportType: ExportTypeCSV()
})
.saveFile()
.always(function() {
    this.destroy();
});
```

Reusing UI Parts: Fragments

Fragments are light-weight UI parts (UI sub-trees) which can be reused, defined similar to views, but do not have any controller or other behavior code involved.

UI parts which are to be used in several views cannot be easily defined. They either have to be created as new controls, or they have to be created as views. Creating them as new controls results in a development overhead, while creating them as separate views results in a runtime overhead. In the latter case they would have a separate controller instead of having the same controller as the view does. Also, views and popup controls like dialogs do not go well together. The dialog content can be defined as a view but the dialog control itself always has to be written in the program.

To solve these issues, fragments have been introduced. They can be reused and, if source code is required and for event handler methods, they can connect to existing controllers of the "owning" view. This means that one important characteristic of fragments is that they are independent of the model-view-controller (MVC) concept and can be used without using MVC. However, if fragments are used together with views and controllers, fragments can make use of them and integrate them neatly.

Similar to `DocumentFragments` in HTML, the fragment itself has no HTML representation when it is inserted into the UI tree. Instead, its content is inserted. This means that fragments are not like controls, but more like a factory creating the contained controls. They support reuse and view modularization without adding overhead.

SAPUI5 provides different types of fragments:

- XML fragments
- HTML fragments
- JS fragments

More fragment types can be implemented and plugged in.

Defining a fragment is similar to defining views within a separate file. The fragments simply end with `*.fragment` instead of `*.view`. Also, the same rules for file location apply.

Model View Controller (MVC) [page 784]
Walkthrough Step 16: Dialogs and Fragments [page 106]

HTML Fragments

HTML fragments have a similar syntax as HTML views, but without the `<template>` tag.

You can define a simple HTML fragment like this:

```
<div data-sap-ui-type="sap.m.Button" data-press="doSomething" data-text="Hello
        World"></div>
```

The fragment is stored as …/my/useful/UiPartZ.fragment.html and referenced as Fragment my.useful.UiPartZ. HTML fragments cannot specify a controller to be instantiated. They can use a controller for binding event handler methods, but only if the code instantiating them passes a controller.

XML Fragments

XML fragments are similar to XML view, but have no <View> tag as root element. Instead, there is an SAPUI5 control.

You define a simple XML fragment as shown in the following code snippet:

```
<Button xmlns="sap.m" id="btnInFragment" text="Hello
    World"/>
```

This simple UI definition can, for instance, be located in a file named …/my/useful/VerySimpleUiPart.fragment.xml, be referenced by its name my.useful.VerySimpleUiPart, and can be found by the module loading mechanism.

A slightly more complex XML fragment can be defined as follows:

```
<VBox xmlns="sap.m">
        <Label text="My Label inside an XML fragment"/>
        <Button id="btnInFragment" text="Hello World" press="doSomething"/>
        <Button text="{/someText}"/>
    </VBox>
```

The event handler is bound to the doSomething method of a controller. This is expressed by the doSomething value of the press event attribute. This means that this fragment can only be instantiated with a controller if the controller has this method. If not, the code throws an error.

You can see how the data binding syntax is the same as that of XML views. Of course, this requires the fragment to be placed into a part of the UI tree where the model is available.

JS Fragments

The structure of JS fragments is similar to the structure of the respective views: They have a name and an object with a createContent() function.

You define a simple JS fragment named my.useful.UiPartX as shown in the following code snippet:

```
sap.ui.jsfragment("my.useful.UiPartX", {
    createContent: function(oController ) {
        var oButton = new sap.m.Button({
            text:"Hello World",
            press:oController.doSomething
        });
        return oButton;
    }
});
```

The createContent() function is responsible for the UI definition and has to return a control. The definition can be created either inline or in a separate file, for instance in …/my/useful/UiPartX.fragment.js. The

`oController` is either already defined or it is null. In the first case, its methods can be used for the event handlers of controls.

Despite the many similarities to views, there are also differences: First of all, there is no `getControllerName()` method. Fragments cannot specify whether they have a controller. Whether `oController` is defined or not is not a decision of the fragment itself. Instead, it is decided by the code instantiating the fragment. If that code is part of a controller, it can pass a reference to itself to the fragment. This means there can be a dependency between controllers and fragments: Fragments may expect a controller to exist and to have certain methods. And controllers may expect certain controls to be in the fragment. This is in line with the purpose of fragments - to be very light-weight re-use entities that provide little encapsulation. For more encapsulation, views or even components are better suited.

Views [page 787]

Instantiation of Fragments

SAPUI5 provides the generic function `sap.ui.fragment()` to instantiate fragments.

Comparing fragments to views, there is one important difference: Fragments are no controls. While views are control instances which have their own HTML and their own set of properties and may contain other controls, fragments just consist of their content. Views contain their content controls, while fragments consist of their content controls.

For example, when a fragment containing a button is instantiated, the result is just this button.

The generic function `sap.ui.fragment()` can be called with either the name, the type, and optionally a controller, or with a configuration object and an optional controller. It either returns the root control contained in the fragment or an array of root controls, depending on the type of the fragment. This fragment type is usually known in advance. Therefore, a specific method for each fragment type can be used to programmatically instantiate a fragment. You find more information on the instantiation process in the respective topics linked in the related link section below.

The different methods used for the instantiation of a fragment have the following commonalities:

- A fragment name must be given. This name must be resolvable to the fragment file URL by the SAPUI5 module loading mechanism. In case of JS fragments the name may also be defined inline.
- A controller can be optionally given. Some fragments may require a controller and certain methods to be present in this controller.
- An ID can be optionally given.
  If no ID is given, any control IDs specified in the fragment are used as is. The repeated use of a fragment can lead to duplicate IDs. One way to avoid that problem is to specify a unique fragment ID. For more information see Unique IDs [page 1011]. This ID will then be used as prefix for all controls in this fragment instance.

Programmatically Instantiating JS Fragments

For each fragment type, SAPUI5 provides a method that can be used to programmatically instantiate a fragment.

Context

To give an example of a programmatic instantiation of a JS fragment, you first have to define one. The following code presents an example definition:

```
sap.ui.jsfragment ( "my.useful.UiPartX",{
    createContent: function (oController ) {
        var oButton  = new sap.m.Button({
            text: "Hello World" ,
            press:oController.doSomething
        });
        return oButton;
    }
});
```

This fragment can be instantiated from a controller as follows:

```
var myButton = sap.ui.jsfragment("my.useful.UiPartX",this); // assuming "this"
is the controller
```

This button can now be used as if it had been created in a standard way. Note how a controller instance is passed as second parameter. This is required because that particular fragment tries to bind the button press handler to the method `doSomething` in the given controller. With no controller given, this would cause an error.

For fragments that are used several times, an ID for the fragment can be given optionally, see Unique IDs [page 1011]:

```
var myButton = sap.ui.jsfragment("someId", "my.useful.UiPartX", this); //
assuming "this" is the Controller
```

Within a JS view's `createContent()` method the fragment content could be included like this:

```
...
    createContent: function (oController ) {
        var hLayout = new sap.m.HBox ();
        ...
        var myFragment = sap.ui.jsfragment( "my.useful.UiPartX" , oController );
        // here the fragment is instantiated
        hLayout.addContent (myFragment );
        ...
        return hLayout ;
    }
...
```

The fragment content (= the button) would be added to the layout which is the content of this JSView. Other fragments not requiring a controller can of course be instantiated without passing a controller. But it also does not hurt to pass the controller - it is only used for setting up the event handlers (or within the `createContent()` method, in case of JS fragments).

Programmatically Instantiating XML Fragments

For each fragment type, SAPUI5 provides a method that can be used to programmatically instantiate a fragment.

Context

To give an example of a programmatic instantiation of an XML fragment, you first have to define one. The following code presents an example definition:

```
<Button xmlns="sap.ui.commons" id="btnInFragment" text="Hello World" />
```

This fragment can be instantiated from a controller as follows:

```
sap.ui.require(["sap/ui/core/Fragment"], function(Fragment) {
    Fragment.load({
        name: "my.useful.VerySimpleUiPart"
    }).then(function(myButton) {
        // ...
    });
});
```

> **i** Note
>
> This specific fragment does not use a controller; if controls inside a fragment needs methods that are to be defined in a controller, the controller has to be referred to in an additional parameter.

Fragments can be instantiated from JSViews, as well. Fragments of any type can be used within views of any type.

If XML fragments are used within XML views, giving the view ID as fragment ID will allow calling `this.byId(…)` in the view's controller to retrieve controls inside the fragment. The following code inside the controller will instantiate the above fragment with the `Button` and then again retrieve the `Button`:

```
sap.ui.require(["sa/ui/core/Fragment"], function(Fragment) {
    Fragment.load({
        name: "my.useful.VerySimpleUiPart"
    }).then(function(myButton) {
        // ...
    });
});
var theSameButton = this.byId("btnInFragment"); // returns the button in the
fragment
```

Programmatically Instantiating HTML Fragments

For each fragment type, SAPUI5 provides a method that can be used to programmatically instantiate a fragment.

Context

To give an example of a programmatic instantiation of an HTML fragment, you first have to define one. The following code presents an example definition:

```
<div data-sap-ui-type="sap.m.Button" data-press="doSomething" data-text="Hello
World"></div>
```

This fragment can be instantiated from a controller as follows:

```
sap.ui.require(["sap/ui/core/Fragment"], function(Fragment) {
    Fragment.load({
        type: "HTML",
        name: "my.useful.UiPartZ",
        controller: oController // this specific fragment again needs a
controller
    }).then(function(myButton) {
        // ...
});
```

This instantiation can be done at any place in the code, given that a controller is available and the returned `button` can be used like any `button`.

Instantiating Fragments in Declarative Views

Example, how all three types of fragments can be instantiated in an XML view.

Context

In XML views, fragments are used like regular controls, or more precisely, like views.

The following code example shows an XML view that includes all three types of fragments, that is an XML fragment, a JS fragment and an HTML fragment. Each type is instantiated once without a given ID and once with a given ID. These fragment references basically work like import statements including the fragment content controls.

```
<mvc:View xmlns:mvc="sap.ui.core.mvc" xmlns:core="sap.ui.core"
controllerName="testdata.fragments.XMLViewController" >

    <core:Fragment               fragmentName="my.useful.SimpleUiPart"
type="XML" />
    <core:Fragment id="xmlInXml" fragmentName="my.useful.SimpleUiPart"
type="XML" />
```

```
    <core:Fragment              fragmentName="my.useful.UiPartX" type="JS" />
    <core:Fragment id="jsInXml" fragmentName="my.useful.UiPartX" type="JS" />

    <core:Fragment                fragmentName="my.useful.UiPartZ" type="HTML" />
    <core:Fragment id="htmlInXml" fragmentName="my.useful.UiPartZ" type="HTML" />
</mvc:View>
```

Related Information

Unique IDs [page 1011]
Using Other Objects Instead of Controllers [page 1010]

Using Other Objects Instead of Controllers

For the instantiation of fragments, the oController object must not necessarily be a controller. It can also be another object.

Context

The oController object given when instantiating a fragment does not need to be an object of type `sap.ui.core.mvc.Controller`. It is entirely up to the fragment what to expect from this object. This object is passed to the `createContent` method of JS fragments. In case of the declarative fragment types, that is XML, or HTML fragments, the event handler methods are searched on this object. This means that in most cases instead of a real controller object any JavaScript object could be given - provided it has the required methods.

The following example of an HTML fragment can be used in an environment where no MVC is used.

```
var oDummyController = {
    doSomething: function() {
        // do whatever should happen when the button in the fragment is pushed...
    }
};
var myButton  = sap.ui.htmlfragment( "my.useful.UiPartZ", oDummyController);
// this specific fragment needs a controller and gets a dummy controller here.
```

Inline Definition and Instantiation of Fragments

Instead of defining fragments externally in a separate file, they can also be defined inline and can be instantiated immediately.

The content definition and also the instantiation syntax are just the same compared to an instantiation in a program. However, instead of the "fragmentName" the "fragmentContent" needs to be given. This feature can

both be used for prototyping or for dynamic fragment composition or for loading fragment content from sources which are not accessible by the normal module loading mechanism. In general, inline definition of fragments plays only a minor role.

JS fragment definitions can be done both inline and within a separate file without any changes. Example inline definitions of XML and HTML fragments are displayed in the following code examples:

Example of an Inline XML Fragment

```
// define the XML fragment as a string (or load it from anywhere)
var myXml = '<Panel xmlns="sap.m" text="Hello World"><Button text="Hello
World"></Button></Panel>';
// use this XML string as "fragmentContent"
var oFragment = sap.ui.xmlfragment({fragmentContent:myXml}); // oFragment is now
the Panel Control
// put the Fragment content into the document
oFragment.placeAt('content');
```

Example of an Inline HTML Fragment

```
// define the HTML fragment as a string (or load it from anywhere)
var myHtml = '<div data-sap-ui-type="sap.m.Button" data-text="Hello World"></
div>';
// use this HTML string as "fragmentContent"
var oFragment = sap.ui.htmlfragment({fragmentContent:myHtml}); // oFragment is
now the Button Control
// put the Fragment content into the document
oFragment.placeAt('content');
```

Related Information

Programmatically Instantiating JS Fragments [page 1007]

Unique IDs

You can use a unique ID for a fragment that will be used as a prefix for all controls in a fragment instance.

In SAPUI5, IDs are either automatically generated or given as string constants by the application developer.

In MVC views, another type of reusable components, all IDs that are given as static strings inside the declarative views (XML, HTML, JSON) are automatically prefixed with the view ID. For JS views and for controls created in the controller code of declarative views, no automated prefixing exists. Instead, we recommend using the `View.createId()` method to prefix the ID and ensure there are no ID collisions even when the view is used multiple times within the same page.

The method `View.byId()` is used to handle these prefixed IDs.

Fragments, however, are meant to be a more light-weight concept of separating and reusing UI parts. What's more, there are no fragment instances involved which could have IDs and handle ID prefixing helper functions (in contrast to view instances). For this reason, stable IDs in fragments are used "as is" by default, meaning they are not prefixed to make them unique. If no ID is given, it will be generated. However, if a fragment is intended to be used more than once within one application, the prefixing mechanism can still be used by giving an ID when instantiating the fragment.

The basic principle is as follows: When a control ID is defined, declarative views add a prefix and the code in views should add a prefix. Fragments also add a prefix if they have a defined ID.

To get rid of the prefixes, the instance method `View.byId()` can be used with the static method `sap.ui.core.Fragment.createID()` if required, that is, if a fragment added a prefix.

> **i** Note
>
> Do **not** rely on the specific prefixing syntax because it may change at some point. Always use methods like `byId()` and `createId()`.

Related Information

IDs in Declarative XML or HTML Fragments [page 1012]
IDs in JS Fragments [page 1013]
IDs of Fragments in Views [page 1013]

IDs in Declarative XML or HTML Fragments

If a fragment with a control ID is instantiated twice without giving an ID, a duplicate ID error occurs.

Given the following XML fragment example:

```
<HBox xmlns="sap.m">
   <Button                    text="Hello World" />
   <Button id="btnInFragment" text="Hello World" />
</HBox>
```

The first button will always have a generated ID, as, for instance, `__button2`. This is regardless of how the fragment is instantiated or whether it resides inside a view.

The second button will either have the ID `btnInFragment`, in case the fragment is instantiated without giving an ID. This approach is easy to use, but implies the risk of ID collisions when instantiated multiple times:

```
sap.ui.htmlfragment("my.useful.UiPartZ"); // Button ID will not be prefixed
```

The other possible ID of the second button is `myFragment--btnInFragment`, in case the fragment is instantiated giving the ID `myFragment`. You should not rely on the exact syntax of this prefixing.

```
sap.ui.htmlfragment("myFragment", "my.useful.UiPartZ");
```

It is, however, possible that a containing view may add its prefix. For more information, see IDs of Fragments in Views [page 1013].

IDs in JS Fragments

The fragment logic of JS fragments cannot influence the IDs of controls that are created in the `createContent()` method.

This behavior is similar to how JS views behave regarding IDs. When a stable ID is given within a JS fragment, the `this.createId()` method should be used:

```
createContent: function(oController ) {
    var oButton  = new sap.m.Button(this.createId("btnInJsFragment"), {
    // use createId() to let the fragment influence the ID
        text: "Hello JS World"
    });
    return oButton ;
}
```

If an ID is given when the fragment is instantiated, `createId()` will add it as prefix. Else, `createId()` will leave the given ID untouched.

It is, however, possible that a containing view may add its prefix. For more information, see IDs of Fragments in Views [page 1013].

IDs of Fragments in Views

For fragments that are used within declarative views, generated IDs are not prefixed.

The following rules apply for given IDs:

- Given IDs are prefixed with only the view ID when no fragment ID was given
- Given IDs are prefixed with both view ID and fragment ID when a fragment ID was given

Related Information

Example: JS Fragments Used in XML Views [page 1014]

Retrieving Control Instances by Their ID

A control instance can be found in a fragment by means of its ID.

Context

Due to the above prefixing that guarantees unique IDs, there are different cases possible which require different calls.

Assuming the control has the ID `myControl`, there are two ways how to retrieve it by its ID.

- Retrieving a control instance when the fragment is not part of a view
  - When no fragment ID was given: `myControl = sap.ui.getCore().byId("myControl")`
  - When a fragment ID `myFrag` was given: `myControl = sap.ui.core.Fragment.byId("myFrag", "myControl")`
- Retrieving a control instance when the fragment is embedded into a view and the code is inside a controller. The controller is called `this` in the following examples.
  - When no fragment ID was given: `myControl = this.byId("myControl")`
  - When a fragment ID `myFrag` was given: `myControl = this.byId(sap.ui.core.Fragment.createId("myFrag", "myControl"))`

Example: JS Fragments Used in XML Views

Example of a JS fragment used in an XML view

The example uses different combinations. Make sure that the `sap-ui-core.js` script location points to an existing SAPUI5 installation.

    <body class='sapUiBody'>
        <div id='content'></div>
    </body>
</html>
```

Dialogs and other Popups as Fragments

You can use fragments to declaratively define dialogs and other popup controls which are not part of the normal page UI structure.

This is a huge advantage over views that do not support this use. The main reason for this is that the view control is always a wrapper around the view content.

Defining Dialogs as Fragments

You can use fragments for the definition of dialogs.

Context

To use fragments for defining popups, just let the root control of the fragment be a dialog or similar control.

The following shows an XML fragment dialog example:

```
<Dialog xmlns="sap.m" title="XML Fragment Dialog">
    <TextView text="{/dialogText}" />
    <buttons>
        <Button text="Close" press="closeDialog"/>
    </buttons>
</Dialog>
```

Other fragment types are used the same way to define, for instance, a dialog as fragment.

For example, in JS fragments, the `createContent()` method returns a dialog control:

```
sap.ui.jsfragment("testdata.fragments.JSFragmentDialog", {
    createContent: function(oController) {
     var oDialog = new sap.m.Dialog({
            title: "JavaScript Fragment Dialog",
            content: [
                new sap.m.Input({
                    text: "{/dialogText}"
                })
            ],
            buttons: [
                new sap.m.Button({
                    text: "Close",
                    press: function(){
                        oDialog.close();
```

```
                    }
                })
            ]
        return oDialog;
    }
});
```

Using Dialogs Defined as Fragments

The fragment instantiation function always returns the fragment's root control, which is a dialog control that can be used like any dialog.

Context

In the following example, the dialog is opened immediately:

```
// "Fragment" required from module "sap/ui/core/Fragment"
Fragment.load({type: "XML", name:
"testdata.fragments.XMLFragmentDialog"}).then(function(oDialog) {
    oDialog.open();
});
```

Note that any global model is available for data binding within this dialog. Also any model set on the dialog itself. However, if this dialog is opened from a controller, the model of this controller's view is NOT automatically available within the dialog fragment. The reason for this is that the dialog is not part of the view UI. If the above code for opening the fragment dialog is part of a controller, it could set the view's model on the dialog:

```
// "Fragment" required from module "sap/ui/core/Fragment"
Fragment.load({type: "XML", name:
"testdata.fragments.XMLFragmentDialog"}).then(function(oDialog) {
    oDialog.setModel(this.getView().getModel());
    oDialog.open();
}.bind(this));
```

Alternatively, the special aggregation `dependents` of `sap.ui.core.Element` can be used to connect the dialog to the lifecycle management and data binding of the view:

```
// "Fragment" required from module "sap/ui/core/Fragment"
Fragment.load({type: "XML", name:
"testdata.fragments.XMLFragmentDialog"}).then(function(oDialog) {
    this.getView().addDependent(oDialog);
    oDialog.open();
}.bind(this));
```

Fragments with Multiple Root Nodes

XML fragments and JS fragments can have more than one root control.

In JS fragments, the `createContent()` method can optionally return an array of controls:

```
// "Label" required from module "sap/m/Label"
// "Input" required from module "sap/m/Input"
// "Button" required from module "sap/m/Button"
sap.ui.jsfragment("sap.ui.core.fragmenttest.MultiRootFragment", {
    createContent: function(oController) {
        var oLabel = new Label({text:"These controls are within one multi-root
Fragment:"});
        var oInput = new Input();
        var oButton = new Button({text: "Still in the same Fragment"});
        return [ oLabel, oInput, oButton ];
    }
});
```

As XML documents need to have exactly one root node, to achieve XML fragments with multiple root nodes, an additional `<FragmentDefinition>` tag needs to be added as root element containing the actual root controls. This `<FragmentDefinition>` tag will not have any representation in HTML at runtime; the children are added directly to wherever this fragment is placed.

```
<core:FragmentDefinition xmlns="sap.m" xmlns:core="sap.ui.core">
    <Label text="These controls are within one multi-root Fragment:" />
    <Input />
    <Button text="Still in the same Fragment" />
</core:FragmentDefinition>
```

> **i Note**
>
> For HTML fragments this feature is currently not available.

XML Templating

The XML templating concept enables you to use an XML view as a template. This template is transformed by an XML preprocessor on the source level, the XML DOM, at runtime just before an SAPUI5 control tree is created from the XML source.

The label texts and binding paths in the example below come from SAP Annotations for OData Version 2.0 (http://www.sap.com/Protocols/SAPData) such as `sap:semantics`, and from OData Version 4.0 annotations such as `com.sap.vocabularies.UI.v1.Badge`. Much more complex tasks than shown in this simple example are possible.

> **i Note**
>
> HTML templating is no longer supported as of version 1.56.

The transformation happens if a preprocessor for XML is called when the view is created, see lines 4 and 5 in the *Calling the XML Preprocessor* example. This preprocessor can be given one or more models along with a corresponding binding context, see lines 6 and 9; this concept exists for any SAPUI5 control's constructor. Typically, an OData model's meta model is given, along with the meta context corresponding to a data path.

XML templating operates on meta data. If the data changes, the XML templating can **not** be executed again. This is due to the processing time. Only the resulting bindings are evaluated again.

If the view is loaded asynchronously, fragments and required modules are loaded asynchronously, too.

> **!** Restriction
>
> XML templating is not directly supported with routing, that is, there is no way to declare that the XML Preprocessor should run on the target view of a route. Instead, you should define a JavaScript view as the route's target and use that view's `createContent` method to create an XML view with templating. In case you need access to models (which are not yet available in that hook), you should return some dummy content first (for instance sap.m.HBox), register to the view's modelContextChange event and create the inner view in that event's handler, finally adding it to the dummy content.
>
> JavaScript Target View For Routing
>
> ```
> sap.ui.jsview("some.package.RouteTargetView", {
>     createContent : function () {
>         return sap.ui.view({
>             async : true,
>             preprocessors : {
>                 xml : {
>                     // ...
>                 }
>             },
>             type : sap.ui.core.mvc.ViewType.XML,
>             viewName : "some.package.TemplateView"
>         });
>     }
> });
> ```

In the example, `sPath = "/ProductSet('HT-1021')/ToSupplier"` and the corresponding meta context point to `"/dataServices/schema/0/entityType/0"` (the entity type `BusinessPartner`). The resulting view is bound to the data path within the OData model in order to display the supplier of that product.

Example: Calling the XML Preprocessor

```
1   View.create({
2      async : true,
3      models : oModel,
4      preprocessors : {
5         xml : {
6            bindingContexts : {
7               meta : oMetaModel.getMetaContext(sPath)
8            },
9            models : {
10              meta : oMetaModel
11           }
12        }
13     },
14     type : ViewType.XML,
15     viewName : "sap.ui.core.sample.ViewTemplate.tiny.Template"
16  }).then(function (oTemplateView) {
17     oTemplateView.bindElement(sPath);
18     ...
19  }
```

The XML preprocessor traverses the view's XML DOM in a depth-first, parent-before-child manner and does the following:

- All XML attributes which represent an available binding, that is, a binding based only on models available to the preprocessor, are replaced by the result of that binding. Formatters and so on can be used as with any SAPUI5 binding.
- XML fragments are inlined; that is, the reference is replaced by the fragment's XML DOM and preprocessing takes place on that DOM as well.
- The preprocessing instructions `<template:with>`, `<template:if>` and `<template:repeat>` are processed.

Example: Component.js

Template.view.xml

Field.fragment.xml

Resulting XML View

See sample sap.ui.core.sample.ViewTemplate.tiny. This sample is based on OData Version 4.0 annotations. It consists of the following three pieces:

- A component controller that creates an OData model (line 17), waits for the meta model to be loaded (line 28) and then creates a template view (line 29) as its content. A preprocessor for XML is requested (line 31) and settings are passed to it, namely the meta model and the binding context that identifies the starting point within that model. The resulting view is bound to the actual data (model and path).
- A template view that includes a fragment twice (line 20 and 25) to demonstrate how to reuse code.
- An XML fragment that demonstrates a simple test (line 10), using expression binding.

> → Tip
>
> You can find more elaborate XML templating samples here: XMLView.
>
> Take a look at the demo scenario for a complete overview of all OData v4 notations.

> ⚠ Caution
>
> The OData model is based on `GWSAMPLE_BASIC` and will not work unless a suitable proxy for back-end access is used. For simplicity, no mock data is included in this example.
>
> For more information, see the Help topic, Sample Service - Basic.

20                  <core:Fragment
fragmentName="sap.ui.core.sample.ViewTemplate.tiny.Field" type="XML"/>
21              </template:with>
22
23              <Label text="{path: 'badge>SecondaryInfo/Label', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}"/>
24              <template:with path="badge>SecondaryInfo" var="field">
25                  <core:Fragment
fragmentName="sap.ui.core.sample.ViewTemplate.tiny.Field" type="XML"/>
26              </template:with>
27          </form:SimpleForm>
28      </template:with>
29  </mvc:View>
```

```
1   <core:FragmentDefinition
2       xmlns="sap.m"
3       xmlns:core="sap.ui.core"
4       xmlns:template="http://schemas.sap.com/sapui5/extension/
sap.ui.core.template/1">
5
6       <!-- "field" MUST point to a
com.sap.vocabularies.Communication.v1.DataField -->
7       <HBox>
8           <template:with path="field>Value"
helper="sap.ui.model.odata.AnnotationHelper.resolvePath" var="target">
9               <!-- go to entity type's property and check SAP Annotations for
OData Version 2.0 -->
10              <template:if test="{= ${target>sap:semantics} === 'tel'}" >
11                  <core:Icon src="sap-icon://phone" width="2em"/>
12              </template:if>
13          </template:with>
14          <Text text="{path: 'field>Value', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}"/>
15      </HBox>
16  </core:FragmentDefinition>
```

The result is equivalent to the following handwritten XML view. Any references to the meta model are gone. Type information has been inserted into the bindings and an `"odata.concat"` expression for `badge>MainInfo/Value` has been processed by `sap.ui.model.odata.AnnotationHelper.format`, concatenating the company name and legal form.

```
<mvc:View xmlns="sap.m" xmlns:core="sap.ui.core" xmlns:form="sap.ui.layout.form"
xmlns:mvc="sap.ui.core.mvc">
  <form:SimpleForm>
    <form:title>
      <core:Title text="{path : 'BusinessPartnerID', type :
'sap.ui.model.odata.type.String', constraints :
{'maxLength':'10','nullable':'false'}}"/>
    </form:title>
    <Label text="Name"/>
    <Text text="{path : 'CompanyName', type : 'sap.ui.model.odata.type.String',
constraints : {'maxLength':'80'}} {path : 'LegalForm', type :
'sap.ui.model.odata.type.String', constraints : {'maxLength':'10'}}"/>
```

```
    <Label text="Phone"/>
    <HBox>
      <core:Icon src="sap-icon://phone" width="2em"/>
      <Text text="{path : 'PhoneNumber', type :
'sap.ui.model.odata.type.String', constraints : {'maxLength':'30'}}"/>
    </HBox>
    <Label text="Web"/>
    <HBox>
      <Text text="{path : 'WebAddress', type : 'sap.ui.model.odata.type.String',
constraints : {}}"/>
    </HBox>
  </form:SimpleForm>
</mvc:View>
```

Summary

Overall, XML templating is based on:

- Preprocessing instructions such as `<template:if>`, which can be used inside XML views
- An OData meta model which offers a unified access to both, OData V2 metadata and OData V4 annotations
- A set of OData type implementations which add knowledge of OData types to SAPUI5
- Expression binding which facilitates the use of expressions instead of custom formatter functions
- The helper class `sap.ui.model.odata.AnnotationHelper` that offers formatter and helper functions to be used inside XML template views. It knows about the OData meta model and helps with standard tasks like accessing a label or providing a runtime binding path. It brings in the OData types, along with their facets. Its output uses expression binding, if needed.

> **i Note**
>
> XML Templating works almost the same for OData V4 as for OData V2; for the differences see the *Annotations* section in Meta Model for OData V4 [page 956].

`sap.ui.model.odata.AnnotationHelper`

Preprocessing Instructions

Preprocessing intructions are processed by the XML preprocessor when it traverses the view's `XML DOM`.

> **i** Note
>
> A model name can be seen as a variable with a value that consists of two parts: a model instance and a binding context path.

You can base conditions on the available variables. XML attributes that represent an available binding are replaced automatically.

with

The `<template:with>` instruction can be used to change a variable's value or to add a variable with a new name.

This changed variable is available only within the scope of the `with` instruction. In the example titled **"with" Template**, `"meta>com.sap.vocabularies.UI.v1.Badge"` refers to `"/dataServices/schema/0/entityType/0/com.sap.vocabularies.UI.v1.Badge"` within `oMetaModel`. `"badge"` then becomes a valid model name while processing the content of the `with` instruction, in addition to the existing ones:

- meta = `oMetaModel, "/dataServices/schema/0/entityType/0"`
- badge = `oMetaModel, "/dataServices/schema/0/entityType/0/com.sap.vocabularies.UI.v1.Badge"`

If you omit the "var" attribute, the same model name will be reused; for example, "meta" in our example, and the `with` instruction changes the binding context locally. A new variable name improves readability.

Example: "with" Template

```
<template:with path="meta>com.sap.vocabularies.UI.v1.Badge" var="badge">
    <!-- ... -->
</template:with>
```

A helper can be called from a `with` instruction. It receives an `sap.ui.model.Context` object identifying the model and path from the instruction's "path" property and may return one of the following:

- A `sap.ui.model.Context` object that is assigned to the variable
- A non-empty string that is used as a path within the same model and assigned to the variable
- Undefined, in which case the helper is ignored and the original path is assigned to the variable
- A thenable (usually a Promise) resolving with any of the above, if the view is loaded asynchronously.

The helper can analyze the object the path points to and derive a "resolved path" from that, such as by normalization or following references. Typically, it only points to a different path, but it can even change the model instance, such as jumping from a data model to its meta model or jumping to a resource model, and so on.

The example titled **"with" Template Including Helper** assumes that "field" is an OData meta model with a current binding context that points to a field inside some annotation, such as `"/dataServices/schema/0/entityType/0/com.sap.vocabularies.UI.v1.Badge/MainInfo"`. The helper function `sap.ui.model.odata.AnnotationHelper.resolvePath` is used to follow the field value's `path` property. For more information, see Annotation Helper [page 1035] and API Reference: `sap.ui.model.odata.AnnotationHelper.resolvePath`.

It returns a path inside the meta model which refers to the corresponding property's meta data, such as `"/dataServices/schema/<i>/entityType/<j>/property/<k>"`. This result is in turn assigned by the `with` instruction to the variable named "target".

Example: "with" Template Including Annotation Helper

```
<template:with path="meta>Value"
helper="sap.ui.model.odata.AnnotationHelper.resolvePath" var="target">
  <template:if test="{= {target>sap:semantics} === 'email'}" >
    <core:Icon src="sap-icon://email" />
  </template:if>
  <template:if test="{= {target>sap:semantics} === 'tel'}" >
    <core:Icon src="sap-icon://phone" />
  </template:if>
</template:with>
```

Related Information

Annotation Helper [page 1035]

repeat

The `<template:repeat` instruction iterates the `sap.ui.model.ListBinding` given by the `list` attribute.

> **i Note**
>
> Sorting and filtering is already supported by the list binding via an extended syntax. For more information, see Sorting, Grouping, and Filtering for List Binding [page 833].

The `var` attribute holds the name of the loop variable which can be used to access the current list element in a child element of `repeat`. In the preprocessing, `repeat` is replaced by multiple clones of its content, one clone per list element, with each clone again preprocessed as if it were contained in a `with` instruction defining the loop variable.

The following example iterates all fields in the identification annotation from the SAP UI vocabulary in the currently referenced element of the model `meta` and displays a label and content for each field. It is completely transparent to the `repeat` implementation whether the list binding refers to data or meta data. The templating engine is replacing "template time" binding expressions which refer to meta data with corresponding runtime

binding expression which refer to data. The formatter `sap.ui.model.odata.AnnotationHelper.format` is used, which encapsulates knowledge about the SAP UI vocabulary and so on.

Example: Template for "repeat" Instruction

```
<template:repeat list="{meta>com.sap.vocabularies.UI.v1.Identification}"
var="field">
  <Label text="{path: 'field>Label', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}" />
  <Text text="{path: 'field>Value', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}" />
</template:repeat>
```

Example: Output Template for the "repeat" Instruction (in Memory Only)

```
<Label text="Product ID" />
<Text text="{path:'ProductID',type:'sap.ui.model.odata.type.String',constraints:
{"nullable":false,"maxLength":10}}" />
<Label text="Price" />
<Text text="{path:'Price/
Amount',type:'sap.ui.model.odata.type.Decimal',constraints:{"precision":
13,"scale":3}}" />
<Label text="Category" />
<Text text="{path:'Category',type:'sap.ui.model.odata.type.String',constraints:
{"maxLength":40}}" />
<Label text="Supplier" />
<Text
text="{path:'SupplierName',type:'sap.ui.model.odata.type.String',constraints:
{"maxLength":80}}" />
```

Example: Template for the "repeat" Instruction with `startIndex` and `length`

You can start the iteration at an index other than 0 or limit the length of the iterated list in the usual manner. For this, specify `startIndex` and `length`. Both are optional and the defaults are 0 for `startIndex` and full length for `length`.

```
<template:repeat
list="{path:'entityType>com.sap.vocabularies.UI.v1.Identification',startIndex:
1,length:3}" var="field">
  <!-- ... -->
</template:repeat>
```

As the OData meta model supports filtering by name, you can repeat all `FieldGroup` annotations regardless of their qualifier.

> **i Note**
>
> In JSON content, the annotation can be called `com.sap.vocabularies.UI.v1.FieldGroup` or `com.sap.vocabularies.UI.v1.FieldGroup#Dimension`, and so on, depending on its qualifier. The filter that is used in the following code snippet for the `<template:repeat>` instruction uses the special path name `@sapui.name` which refers back to the name of the object that is inspected for filtering. This name is, for example, `com.sap.vocabularies.UI.v1.FieldGroup#Dimension`.

Example: Filter By Annotation Term

```
<template:repeat list="{path:'entityType>', filters: {path: '@sapui.name',
operator: 'StartsWith', value1: 'com.sap.vocabularies.UI.v1.FieldGroup'}}"
var="fieldGroup">
  <form:SimpleForm>
    <form:title>
```

```
      <core:Title text="{path: 'fieldGroup>Label', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}"/>
    </form:title>
    <template:repeat list="{fieldGroup>Data}" var="field">
      <Label text="{path: 'field>Label', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}"/>
      <core:Fragment
fragmentName="sap.ui.core.sample.ViewTemplate.scenario.Field" type="XML"/>
    </template:repeat>
  </form:SimpleForm>
</template:repeat>
```

if

The `<template:if>` instruction evaluates a condition expressed via existing SAPUI5 data binding features, such as extended syntax; in the preprocessing it is removed or replaced by its child elements based on the value of this condition.

For more information, see Sorting, Grouping, and Filtering for List Binding [page 833].

You set the condition to the `test` attribute of the `if` instruction. It is recommended to use expression binding if you need to write logical expressions or convert values into Booleans. You can also use formatter functions, as with any SAPUI5 binding, such as `sap.ui.model.odata.AnnotationHelper.isMultiple`. For more information, see `sap.ui.model.odata.AnnotationHelper.isMultiple` in the API Reference.

> **i Note**
>
> The test condition is treated as a property binding and the result is converted to the Boolean type according to the usual JavaScript rules, with the exception of the string `"false"`, which is converted to the Boolean `false` for convenience. For more information about the JavaScript rules, see the ECMAScript® Language Specification on the ECMA International website.

Example: "if" Instruction to Include an Image Only if the URL is Set

The output of the template below after preprocessing is as follows: If the test condition does not hold, the `<template:if>` node is dropped and if the test condition holds, the node is replaced by its content.

```
<template:if test="{meta>ImageUrl}">
  <Image src="{path: 'meta>ImageUrl', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}" />
</template:if>
```

> **i Note**
>
> The example above shows a shortcut syntax where `<template:then>` can be omitted in case no `<template:else>` is present.

Example: "if/then/else" Instruction to Include an Image Only if the URL is Set and Display a Title Otherwise

The syntax of this example is more complex due to the additional `<template:then>/<template:else>` elements. The output is the `<template:if>` node replaced by the content of the appropriate child node.

Sample Code

```
<template:if test="{meta>ImageUrl}">
  <template:then>
    <Image src="{path: 'meta>ImageUrl', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}" />
  </template:then>
  <template:else>
    <Text text="{path: 'meta>Title/Value', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}" />
  </template:else>
</template:if>
```

Example: if/then/else Instruction

It is even possible to check multiple conditions in one `<template:if>` construct using the `<template:elseif>` element as shown in the example below.

```
<template:if test="{meta>ImageUrl}">
  <template:then>
    <m:Image src="{path: 'meta>ImageUrl', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}" />
  </template:then>
  <template:elseif test="{meta>TypeImageUrl}">
    <commons:Image src="{path: 'meta>TypeImageUrl', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}" />
  </template:elseif>
  <template:else>
    <commons:Text text="{path: 'meta>Title/Value', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}" />
  </template:else>
</template:if>
```

Related Information

Expression Binding [page 845]
XML Templating [page 1018]

alias

The `<template:alias>` instruction can be used to define a shortcut alias name for a JavaScript value, for example a static helper class, a formatter function, or a helper function.

The shortcut alias is only available in the scope of the `alias` instruction. Each nested scope can redefine aliases.

A proper relative name must be used. This proper name must not contain or consist of a dot. The value to which the alias refers to can be any JavaScript object or property including a function that is available at that point. Exisiting alias names can be used in new alias definitions to refer to values, for example, `<template:alias name="format" value="AH.format">`. Aliases are inherited into fragments, but of course a fragment may (re)define its own set of aliases. For compatibility reasons, aliases can also start with a dot, both in definition and in references.

Example: "alias" Template

```
<template:alias name="AH" value="sap.ui.model.odata.AnnotationHelper">
  <template:with path="meta>com.sap.vocabularies.UI.v1.Badge" var="badge">
    <form:SimpleForm>
      <form:title>
        <core:Title text="{path: 'badge>HeadLine', formatter: 'AH.format'}"/>
      </form:title>
      <Label text="{path: 'badge>Title/Label', formatter: 'AH.format'}"/>
      <Text text="{path: 'badge>Title/Value', formatter: 'AH.format'}"/>
      <Label text="{path: 'badge>MainInfo/Label', formatter: 'AH.format'}"/>
      <template:with path="badge>MainInfo" var="field">
        <core:Fragment fragmentName="sap.ui.core.sample.ViewTemplate.tiny.Field"
type="XML"/>
      </template:with>
      <Label text="{path: 'badge>SecondaryInfo/Label', formatter: 'AH.format'}"/>
      <template:with path="badge>SecondaryInfo" var="field">
        <core:Fragment fragmentName="sap.ui.core.sample.ViewTemplate.tiny.Field"
type="XML"/>
      </template:with>
    </form:SimpleForm>
  </template:with>
</template:alias>
```

require

The `template:require` attribute can be used at the root element of an XML template view or fragment. You can specify a list of required modules as Unified Resource Names, similar to `sap.ui.require`, and assign aliases to them using a JSON-like syntax. The aliases can then be used to access the modules in the same way `<template:alias>` works. (This requires that the view is loaded asynchronously.)

> **i** Note
>
> The aliases can be used for formatter references (first `text` element in the code sample) as well as for function calls inside an expression binding (second `text` element in the code sample).

Example: "require" Template

```
<mvc:View
  controllerName="sap.ui.core.sample.ViewTemplate.scenario.Detail"
  template:require="{Helper: 'sap/ui/core/sample/ViewTemplate/scenario/Helper',
    AnnotationHelper: 'sap/ui/model/odata/AnnotationHelper'}"
  xmlns:mvc="sap.ui.core.mvc"
  xmlns:template="http://schemas.sap.com/sapui5/extension/
sap.ui.core.template/1">
<template:alias name="bar" value="Helper.bar">
<Text text="{formatter: 'bar', path: '/foo'}"/>
<Text text="{= bar(${/foo}) }"/>
```

For compatibility reasons, especially if the view is loaded synchronously, the `template:require` attribute may contain a space-separated list of module names for `jQuery.sap.require`. These modules will then be required before processing. You have to access them via their global names.

`sap.ui.model.odata.AnnotationHelper` is automatically available.

Example

```
<mvc:View
  controllerName="sap.ui.core.sample.ViewTemplate.scenario.Detail"
  template:require="sap.ui.core.sample.ViewTemplate.scenario.Helper"
  xmlns:mvc="sap.ui.core.mvc"
  xmlns:template="http://schemas.sap.com/sapui5/extension/
sap.ui.core.template/1">
```

Replacement of Bindings

For attributes, SAPUI5 binding expressions are used instead of preprocessing instructions. If the value of an XML attribute represents a valid SAPUI5 binding which refers to currently available model (= `<variable>`) names only, the binding is evaluated and the result is written back into the XML attribute.

The `sap.ui.model.odata.AnnotationHelper.format` method can be used as a formatter which properly interprets OData Version 4.0 annotations from the OData meta model. You can use the same formatter for labels and values. For more information, see SAP Annotations for OData Version 2.0.

Formatters for labels are usually not needed. Instead, pointing to `'badge>MainInfo/Label/String'` could be used, but this does not take care of escaping and works only for string constants. The `sap.ui.model.odata.AnnotationHelper.format` inserts references to translatable texts in case the preprocessor has been called with `bindTexts : true`. This is important for design-time templating.

The following example shows a template with binding:

```
<Label text="{path: 'badge>MainInfo/Label', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}"/>
<Text text="{path: 'field>Value', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}" />
```

At the time the binding is resolved, `field>Value` refers to `meta>/dataServices/schema/0/entityType/0/com.sap.vocabularies.UI.v1.Badge/MainInfo/Value`. In the resulting `XML DOM`, the references to the meta model are gone and the type information including the constraints is inserted in the binding. This is shown in the following example:

```
<Label text="Phone"/>
<Text text="{path : 'PhoneNumber', type : 'sap.ui.model.odata.type.String',
constraints : {'maxLength':'30'}}" />
Custom Formatter Functions
```

Custom Formatter Functions

You can also write your own custom formatter functions. For information how you access the model and path related to the current formatter call, see sap.ui.core.util.XMLPreprocessor.IContext.

The following code snippet shows a composite binding example. It assumes that the structure of the meta model that is used corresponds to the structure in the example and that `title>` refers to the header info's title property (line 2 in the code snippet):

```
1   "com.sap.vocabularies.UI.v1.HeaderInfo": {
2       "Title": {
3           "Label": {
4               "String": "Customer"
5           },
6           "Value": {
7               "Path": "CustomerName"
8           }
9       }
10  }
```

The following code snippet shows a formatter function that can be used in composite bindings either at root level (line 1), or for individual parts (Line 2). You can also use it for a simple binding. In this case, it behaves in the same way as a single part.

```
1   <Text text="{path: 'title>Label', formatter: 'formatParts'}: {path:
'title>Value', formatter: 'formatParts'}"/>
2   <Text text="{parts: [{path: 'title>Label', formatter: 'formatParts'}: {path:
'title>Value'}], formatter: 'formatParts'}"/>
```

The following code snippet shows an example formatter function.

```
1   /*
2    * Custom formatter function for complex bindings to demonstrate access to
ith part of binding.
3    * Delegates to {@link sap.ui.model.odata.AnnotationHelper#format} and wraps
label texts in
4    * square brackets. Joins parts together, separated by a space.
5    *
6    * @param {sap.ui.core.util.XMLPreprocessor.IContext} oInterface
7    *   the callback interface related to the current formatter call
8    * @param {...any} [vRawValue]
9    *   the raw value(s) from the meta model
10   * @returns {string}
11   *   the resulting string value to write into the processed XML
12   */
13  window.formatParts = function(oInterface, vRawValue) {
```

```
14      var i, aResult;
15
16      /*
17       * Delegates to {@link sap.ui.model.odata.AnnotationHelper#format} and
wraps label texts
18       * in square brackets.
19       *
20       * @param {sap.ui.core.util.XMLPreprocessor.IContext|
sap.ui.model.Context} oInterface
21       *   the callback interface related to the current formatter call
22       * @param {any} [vRawValue]
23       *   the raw value from the meta model
24       * @returns {string}
25       */
26      function formatLabelValue(oInterface, vRawValue) {
27        var sResult = sap.ui.model.odata.AnnotationHelper.format(oInterface,
vRawValue);
28        return sMyString.endsWith(oInterface.getPath(), "/Label")
29             ? "["+ sResult + "]"
30             : sResult;
31      }
32
33       try {
34          if(oInterface.getModel()) {
35              returnformatLabelValue(oInterface, vRawValue);
36          } else {
37              // root formatter for a composite binding
38              aResult = [];
39              // "probe for the smallest non-negative integer"
40              for (i = 0; oInterface.getModel(i); i += 1) {
41                  aResult.push(
42                      // Note: arguments[i + 1] is the raw value of the ith
part!
43                      formatLabelValue(oInterface.getInterface(i), arguments[i
+ 1])
44                  );
45              }
46              return aResult.join(" ");
47          }
48      } catch (e) {
49          return e.message;
50      }
51  }
52  window.formatParts.requiresIContext = true;
```

This example formatter opts to the extended signature (see line 51), which provides a context interface as the first parameter. It distinguishes between root level calls and others (see line 34), delegates to `sap.ui.model.odata.AnnotationHelper#format` (see line 27), and wraps label texts in square brackets for demo purposes (see line 29). For root level calls, it loops over all available parts (see line 40) and accesses each part (see line 43). The demo code handles each part individually and joins the result, but in practice some more complicated dependency between parts would be realistic.

The delegation to `sap.ui.model.odata.AnnotationHelper#format` provides the raw value we already have at hand, even for root level calls (see comment in line 42).

> **i Note**
>
> The custom formatter function needs to be accessible globally, because XML templating cannot call formatter functions inside the view's controller. This controller does not yet exist at the time of preprocessing. However, it is not sufficient to simply put it into window (see line 8). You must put it into your own namespace.

The example formatter has the following output:

```
<Text text="[Customer]: {CustomerName}"/>
<Text text="[Customer] {CustomerName}"/>
```

> **i Note**
>
> The colon (":") is taken over literally from the first composite binding which consists of two bindings separated by a string literal.

Mixing Runtime Data and Meta Data Within a Single Binding

The following code snippet shows a single binding that mixes runtime data and meta data. This will not work: The binding refers to the runtime and as runtime is not available ar this point, XML templating cannot replace the binding. (In the example, "runtime" stands for the name of the model at runtime. This would typically be the default model and thus has no name.)

```
{= ${runtime>value} > ${meta>threshold} }
```

`meta` will no longer be available anymore, so this binding cannot work as expected, but it will be evaluated every time the value changes and will compare the value to `undefined`.

To solve this, a clear separation is required: One expression binding that refers to meta data only and can be replaced by XML templating, and another expression binding that refers to runtime data only and can be evaluated later on. These two bindings need to be nested as follows:

```
{= '{= ${runtime<value} > ' + ${meta>threshold} + ' }' }
```

XML templating replaces this with a kind of a partial evaluation of the original mixed binding. By carefully putting the pieces into string literals and by taking care of escaping, you have full control over this process of partial evaluation. This is shown in the following examples, where the threshold value is assumed to be a number:

Expression binding with runtime data only:

```
{= ${runtime>value} > 42 }
```

Escaping for string constants:

```
{= '{= \'' + ${meta>A} + '\' + ${/B} } // --> {= 'A' + ${/B} }
```

Using the annotation helper:

```
{= '{= $' + ${path : 'meta>value, formatter :
'sap.ui.model.odata.AnnotationHelper.format'} + ' > ' + ${path :
'meta>threshold',
formatter : 'sap.ui.model.odata.AnnotationHelper.format'} + ' }' }
// --> {= ${path : 'path/to/property/value', type :
'sap.ui.model.odata.type.Int16'} > 42 }
```

XML Templating [page 1018]
Formatting, Parsing, and Validating Data [page 854]

XML Fragments

SAPUI5 fragments of type XML are used in the context of XML templating to provide reuse parts for templates.

Any reference to an XML fragment is inlined by the preprocessor; that is, the reference is replaced by the fragment's XML DOM and preprocessing takes place on that DOM as well. All currently available variable names are inherited into the fragment.

Example: XML Fragment

```
<core:Fragment fragmentName="sap.ui.core.sample.ViewTemplate.tiny.Field"
type="XML"/>
```

The fragment name can also result from a binding, including an expression binding which evaluates to a constant. As formatter functions return strings, and not booleans, `=== 'true'` has been added in the following example:

Example: Dynamic Fragment Name

```
<core:Fragment fragmentName="{= ${path: 'facet>Target', formatter:
'sap.ui.model.odata.AnnotationHelper.isMultiple'} === 'true'
    ? 'sap.ui.core.sample.ViewTemplate.scenario.TableFacet'
    : 'sap.ui.core.sample.ViewTemplate.scenario.FormFacet' }" type="XML"/>
```

Related Information

XML Templating [page 1018]

Extension Points

Extension points can be used in XML templating to extend the standard with custom content.

The extension point has a default content which is used unless the extension point is replaced via customizing. The extension point name can result from a binding, including an expression binding which evaluates to a constant. If the extension point is to be replaced by an XML fragment, the extension point element is replaced by the fragment's XML DOM and preprocessing takes place on the DOM as well. All currently available variable

names and aliases are inherited into the fragment as usual. You get the same debug output as for fragment instructions, and you see the customized fragment name there.

```
<!-- expression binding just to showcase dynamic names -->
<core:ExtensionPoint name="{:= 'HeaderInfo' }">
    <form:SimpleForm>
        <form:title>
            <core:Title text="HeaderInfo"/>
        </form:title>
        <template:with path="entityType>com.sap.vocabularies.UI.v1.HeaderInfo">
            <!-- ... -->
        </template:with>
    </form:SimpleForm>
</core:ExtensionPoint>
```

Annotation Helper

A collection of methods which help to consume OData Version 4.0 annotations in XML template views.

The `AnnotationHelper` connects all the pieces related to XML templating: It knows the OData meta model and its structure as well as the OData v4 annotations. The `AnnotationHelper` offers formatter functions and helper functions. You can call these methods directly from the JavaScript code without XML runtime templating. You do not need to require `sap.ui.model.odata.AnnotationHelper` before use.

> → Tip
>
> You can see more information on the expressions, constants and functions used by the `AnnotationHelper`, in the respective chapters of the specification OData Version 4.0 Specification: Part 3: Common Schema Definition Language .

Formatter Functions

The formatter functions can be used in binding expressions and `<template:if>` instructions for test conditions.

> ℹ Note
>
> To use formatter functions, you need to enable the extended binding syntax by setting the configuration option `xx-bindingSyntax` to `complex`. For more information, see Composite Binding [page 843]. If the extended binding syntax is not enabled and expressions are created by means of the annotation helper's format functions, the following warning is issued in the console: *Complex binding syntax not active*.

The following formatter functions exist:

- `createPropertySetting`: Creates a property setting which is either a constant value or a binding info object from the given parts and from the optional root formatter function. Each part can have one of the following types:
  - boolean, number, undefined: The part is a constant value.
  - string: The part is a data binding expression with complex binding syntax (for example, as created by format) and is parsed accordingly to create either a constant value or a binding info object. Proper backslash escaping must be used for constant values with curly braces.
  - object: The part is a binding info object if it has a "path" or "parts" property, otherwise it is a constant value.

  If a binding info object is not the only part and has a `parts` property itself, then it must have no other properties except `formatter`. This applies to expression bindings and data binding expressions that are created by `format`. If all parts are constant values, the resulting property setting is also a constant value computed by applying the root formatter function to the constant parts once. If at least one part is a binding info object, the resulting property setting is also a binding info object and the root formatter function will be applied again and again to the current values of all parts, no matter whether constant or variable.

  > **i Note**
  >
  > The root formatter function should not rely on its `this` value because it depends on how the function is called.
  >
  > A single data binding expression can be given directly to `applySettings`; you do **not** need to call `this` function first.

- `format`: General purpose method that handles proper escaping and formatting of constant values and provides binding expressions with suitable types. `format` supports the following constructs:
  - The *"14.4 Constant Expressions"* for *"edm:Bool"*, *"edm:Date"*, *"edm:DateTimeOffset"*, *"edm:Decimal"*, *"edm:Float"*, *"edm:Guid"*, *"edm:Int"*, *"edm:TimeOfDay"*.
  - Constant *"14.4.11 Expression edm:String"*: This constant is either turned into fixed text, for example *"Width"*, or into a data binding expression, for example `"{/##/dataServices/schema/0/entityType/1/com.sap.vocabularies.UI.v1.FieldGroup#Dimensions/Data/0/Label/String}"`. If XML template processing has been started with the setting `bindTexts : true`, data binding expressions are used. The constant is used to reference translatable texts from OData v4 annotations, especially for XML template processing at design time. The string constants that contain a simple binding `"{@i18n>...}"` to the hard-coded model name `"@i18n"` with an arbitrary path are not turned into a fixed text, but kept as a data binding expression. This enables local annotation files to refer to a resource bundle for internationalization. If you want to avoid this behaviour, add a space at the end of the string constant and it will be turned into a fixed text again.
  - Dynamic *"14.5.1 Comparison and Logical Operators"*: Turned into an expression binding to perform the operations at runtime
  - Dynamic *"14.5.3 Expression edm:Apply"*:
    - *"14.5.3.1.1 Function odata.concat"*: Turned into a data binding expression relative to an entity
    - *"14.5.3.1.2 Function odata.fillUriTemplate"*: Turned into an expression binding to fill the template at runtime
    - *"14.5.3.1.3 Function odata.uriEncode"*: Turned into an expression binding to encode the parameter at runtime

    The *apply* functions can be nested arbitrarily.

- Dynamic *"14.5.12 Expression edm:Path"* and *"14.5.13 Expression edm.PropertyPath*: This dynamic expression is turned into a data binding relative to an entity including type information and constraints as available from metadata, for example `"{path : 'Name', type : 'sap.ui.model.odata.type.String', constraints : {'maxLength':'255'}}"`.
- Dynamic *"14.5.6 Expression edm:If"*: This dynamic expression is turned into an expression binding to be evaluated at runtime. The expression is conditional, for example, `"{=condition ? expression1 : expression2}"`.

> **i Note**
>
> Unsupported values are turned into strings, and indicated as such. To ensure that the data binding syntax is not corrupted, proper escaping is used.

```
<Text text="{path: 'meta>Value', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}"/>
```

- `getNavigationPath`: Special formatter that extracts a data binding expression for the navigation path from one of the following dynamic expressions: *14.5.2 Expression edm:AnnotationPath*, *"14.5.11 Expression edm:NavigationPropertyPath"*, *"14.5.12 Expression edm:Path"* and *"14.5.13 Expression edm:PropertyPath"*; example:
  - The input value `{AnnotationPath : "ToSupplier/@com.sap.vocabularies.Communication.v1.Address"}` returns `"{ToSupplier}"`
  - The input value `{AnnotationPath : "@com.sap.vocabularies.UI.v1.FieldGroup#Dimensions"}` returns `"{}"`
  - The input value `{}` returns `""`

```
<template:if test="{path: 'facet>Target', formatter:
'sap.ui.model.odata.AnnotationHelper.getNavigationPath'}">
    <form:SimpleForm binding="{path: 'facet>Target', formatter:
'sap.ui.model.odata.AnnotationHelper.getNavigationPath'}" />
</template:if>
```

- `isMultiple`: Special formatter that knows about the one of the following dynamic expressions: *14.5.2 Expression edm:AnnotationPath*, *"14.5.11 Expression edm:NavigationPropertyPath"*, *"14.5.12 Expression edm:Path"* and *"14.5.13 Expression edm:PropertyPath"*. The formatter returns the information whether the navigation path ends with an association end with multiple "*". If the multiple "*" are not the last characters, the formatter returns an error.

```
<template:if test="{path: 'facet>Target', formatter:
'sap.ui.model.odata.AnnotationHelper.isMultiple'}">
```

- `simplePath`: Specialized method useful for design-time templating in connection with smart fields; it can only return simple binding expressions without type information. This has the advantage that the resulting XML view, which is shown at design-time, looks much simpler and nicer without `&quot;` escapes.
  Example:

```
<mvc:View
  xmlns:mvc="sap.ui.core.mvc"
  xmlns:sfi="sap.ui.comp.smartfield"
  xmlns:sfo="sap.ui.comp.smartform"
  xmlns:template="http://schemas.sap.com/sapui5/extension/
sap.ui.core.template/1">
  <sfo:SmartForm title="{path: 'meta>com.sap.vocabularies.UI.v1.HeaderInfo/
TypeName', formatter: 'sap.ui.model.odata.AnnotationHelper.format'}">
    <template:repeat list="{path:'meta>', filters: {path: 'RecordType',
operator: 'EQ', value1: 'com.sap.vocabularies.UI.v1.FieldGroupType'}}">
```

```
      <sfo:Group label="{path: 'meta>Label', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}">
        <template:repeat list="{meta>Data}">
          <sfo:GroupElement label="{path: 'meta>Label', formatter:
'sap.ui.model.odata.AnnotationHelper.format'}">
            <sfi:SmartField value="{path: 'meta>Value', formatter:
'sap.ui.model.odata.AnnotationHelper.simplePath'}"/>
          </sfo:GroupElement>
        </template:repeat>
      </sfo:Group>
    </template:repeat>
  </sfo:SmartForm>
</mvc:View>
```

Output:

```
<mvc:View xmlns:mvc="sap.ui.core.mvc" xmlns:sfi="sap.ui.comp.smartfield"
xmlns:sfo="sap.ui.comp.smartform">
  <sfo:SmartForm title="Sales Order">
      <sfo:Group label="Order Note">
          <sfo:GroupElement label="Text">
            <sfi:SmartField value="{Note}"/>
          </sfo:GroupElement>
      </sfo:Group>
  </sfo:SmartForm>
</mvc:View>
```

The formatter functions can also be called directly from JavaScript. The following code snippet shows an example for the use of a formatter function outside templating:

```
var oModel = this.getModel(),
    sPath = "##com.sap.vocabularies.UI.v1.HeaderInfo/Description/Label",
    oContext = oModel.getContext(oModel.resolve(sPath,
this.getBindingContext())),
    oLabel = new sap.m.Label({
        text : sap.ui.model.odata.AnnotationHelper.format(oContext)
    }));
...
```

The formatter functions are called with a context object as first parameter. The second parameter (`vRawValue`) is optional. If the value is not provided, it is calculated in the formatter function. If the application has already calculated the value, it passes the raw value as second parameter, thus avoiding unnecessary further calculations of the raw value.

Helper Functions

The following helper functions can be used with `<template:with>`:

- `gotoEntityset`: Helper function for a `with` instruction for the entity set with the given name or the entity set that depending on how it is called has been determined by the last navigation property of one of the following dynamic expressions: *14.5.2 Expression edm:AnnotationPath*, *"14.5.11 Expression edm:NavigationPropertyPath"*, *"14.5.12 Expression edm:Path"* and *"14.5.13 Expression edm:PropertyPath"*.

```
<template:with path="facet>Target"
helper="sap.ui.model.odata.AnnotationHelper.gotoEntitySet" var="entitySet" />
<template:with path="associationSetEnd>entitySet"
helper="sap.ui.model.odata.AnnotationHelper.gotoEntitySet" var="entitySet"/>
```

The binding context passed to the helper function, as determined by the `template:with` instruction's `path` property, must point to a simple string or to an annotation (or annotation property) of type `Edm.AnnotationPath`, embedded within an entity set or type; the context's model must be an `sap.ui.model.odata.ODataMetaModel`.

- `gotoEntityType`: Helper function for a `with` instruction that goes to the entity type with the given qualified name. The binding context passed to the helper function, as determined by the `template: with` instruction's `path` property, must point to the qualified name of an entity type; the context's model must be an `sap.ui.model.odata.ODataMetaModel`.
  Example: Assume that `entitySet` refers to an entity set within an OData meta model; the helper function is then called on the `entityType` property of that entity set (which holds the qualified name of the entity type) and in turn the path of that entity type is assigned to the variable `entityType`.

```
<template:with path="entitySet>entityType"
helper="sap.ui.model.odata.AnnotationHelper.gotoEntityType" var="entityType">
```

- `resolvePath` is a helper function for a `template:with` instruction that resolves one of the following dynamic expressions: *14.5.2 Expression edm:AnnotationPath*, *"14.5.11 Expression edm:NavigationPropertyPath"*, *"14.5.12 Expression edm:Path"* and *"14.5.13 Expression edm:PropertyPath"*. The function supports navigation properties and term casts. The binding context passed to the helper function, as determined by the `template:with` instruction's path property, must point to an annotation or annotation property of type `Edm.AnnotationPath`, embedded within an entity type, The context's model must be `sap.ui.model.odata.ODataMetaModel`.

```
<template:with path="meta>Value"
helper="sap.ui.model.odata.AnnotationHelper.resolvePath" var="target">
```

- `gotoFunctionImport`: Helper function for a `template:with` instruction that goes to the function import with the name which `oContext` points at. Example: Assume that `dataField` refers to a `DataFieldForAction` within an OData meta model; the helper function is then called on the `Action` property of that data field (which holds an object with the qualified name of the function import in the String property) and in turn the path of that function import is assigned to the variable `function`.

```
<template:with path="dataField>Action"
helper="sap.ui.model.odata.AnnotationHelper.gotoEntityType" var="function">
```

OData Version 4.0

Debugging

For the debug levels `DEBUG` and `ALL`, the XML preprocessor writes a trace for what it exactly does.

The following events are traced (the numbers represent the line numbers in the example below):

- The start including the view being processed (1)

- A list of all binding contexts with the path they are pointing to (2)
- Start of processing of a `<with>` statement including the new variable assignment (3,6)
- Evaluation of an `<if>` or `<elseif>` statement including the test result (4,10)
- Start of processing of a `<repeat>` statement (8)
- Each iteration of the `<repeat>` statement including the current variable assignment (9)
- Start of processing of a `<Fragment>` statement including the resulting fragment name (7)
- Finished processing of any of the following statements: `<with>`, `<if>`, `<repeat>`, `<Fragment>` (12-17)
- If any attribute of any other node has been resolved (5,11)
- The finish (18)

Each debug line looks as follows:

```
[level] message - <node> sap.ui.core.util.XMLPreprocessor
```

`[level]` is the number of currently active preprocessor statements. It is incremented each time when the processing of an `<if>`, `<with>`, `<repeat>` or `<Fragment>` starts. It is decremented when the node is completely processed. `<node>` is the node being processed with all its attributes.

Example:

```
1  [ 0] Start processing Element sap.ui.core.mvc.XMLView#__xmlview5
(sap.ui.core.sample.ViewTemplate.scenario.Detail) -
sap.ui.core.util.XMLPreprocessor
2  [ 0] meta = /dataServices/schema/0/entityContainer/0/entitySet/0 -
sap.ui.core.util.XMLPreprocessor
3  [ 1] entityType = /dataServices/schema/0/entityType/0 - <template:with

```

Working with Controls

Controls are used to define the appearance and behavior of screen areas.

Controls consist of:

- Control name
  The control name is a string that consists of the library name and the control name, separated by a dot. The library name can be omitted if there is no need to assign the control to a library. It is possible, for example, to use `Square` as control name. For controls that are reused by others, we recommend to use a unique library name, for example `sap.byd.Square`.
- Control metadata
  The metadata defines the properties, events, aggregations and associations of a control.
  Control properties, such as text or width, are used to modify the appearance or to relate to data that is displayed by the control. The controls are defined by the control metadata, which is the public API of the control. The API can be used by applications at runtime and also contains information on runtime features such as data binding and type validation checks.
  Controls can aggregate other controls. These controls with aggregations serve as a container or layout control to which the application can add child controls. They can also serve as composite controls if the control itself adds child controls and reuses available components. In an aggregation, child controls are owned by the parent control and are destroyed together with the parent control. A control can only have one aggregation parent. Adding the control to another aggregation removes it from the previous parent control.
  Associated controls are not part or children of an aggregation control. They are connected by ID instead of reference. Destroying a control in an association does not affect the other control. It is possible that an associated control does not yet or no longer exist.
  Controls fire events. Events typically relate to the control's purpose and functionality on a semantically higher level than browser events such as `click`. Examples for control events are `triggerSearch` for a search field or `collapse` in a panel.
- Elements
  Elements are parts of controls or rather configuration packages for parts of controls. Elements **cannot** be used standalone and do **not** have their own renderer. Instead, the control that uses the element does the rendering: The `ComboBox` control, for example, renders the `Item` elements. The information provided for controls also applies to elements but not to the renderer. The `sap.ui.core.Element` class is the base class of `sap.ui.core.Control`.
- Methods
  By convention, methods are public, unless their name starts with an underscore or if it is one of the special method types. When developing control libraries, public methods must be annotated with `@public` in the JSDoc, and private methods with `@private`. The generated getter/setter methods for properties are also public methods.
  Methods are added to a new control by simply providing the implementation. It is not necessary to add the method to the metadata. Other controls and the application must only call public methods and the control ensures that they remain compatible. There are no technical rules that prevent the call of private methods, but it is not allowed.

The base class for all controls in SAPUI5 is `sap.ui.core.Control`. To inherit and extend the functionality, specific controls can either inherit from the base class, or from another control.

UI Control Constructors

A constructor is a special type of function that is called to create an object. The constructor uses values to set control properties, thus preparing the new object for use.

In SAPUI5, control constructors accept the following arguments in the specified order:

1. An optional unique identifier of type `string` which must either be the first argument, or omitted altogether. If you omit the ID, the SAPUI5 framework automatically computes an ID. Specifying your own identifier allows your application to easily find the control and, for example, retrieve the current user input from it. Alternatively, you can keep a reference to the control in a variable.
2. A simple object as `mSettings` parameter that defines values for any property, aggregation, association, or event.

The following code snippet shows an example of a constructor that is called to create a new text control saying "Hello World" with the specified tooltip and width:

```
// required from sap/m/Text
var oText = new Text("testText",
{text : "Hello World", tooltip: "This is an example tooltip", width: "100px"});
```

The above example is an abbreviated version of the following code snippet with a detailed list of statements, which is alternatively supported:

```
// required from sap/m/Text
var oText = new Text("testText");
oText.setText("Hello World");
oText.setTooltip("This is an example tooltip");
oText.setWidth("100px");
```

The supported parameters are documented in the *API Reference* of the respective control.

Related Information

Developing Controls [page 2158]

Custom Data - Attaching Data Objects to Controls

SAPUI5 provides the `data()` method to attach data objects to controls.

The `data()` method is contained in `sap/ui/core/Element`. You can use this method to set and get data. The API is equivalent to `jQuery.data()`.

The following additional options exist for attaching data to SAPUI5 controls:

- Attaching data declaratively in XML views and JSON views, see XML View [page 787]
- Using data binding, see Data Binding [page 815]
- For strings only: Writing data to the HTML DOM as "data-*" attribute, see Writing Data to the HTML DOM as DATA-* Attribute [page 1045]

Setting and Retrieving Data

To set and retrieve data, use the following code:

```
myButton.data("myData", "Hello");  // attach some data to the Button
alert(myButton.data("myData"));     // alerts "Hello"
var dataObject = myButton.data();  // a JS object containing ALL data
alert(dataObject.myData);          // alerts "Hello"
```

Binding Data: Use in a List Binding

For list bindings, use the following code:

```
// "CustomData" required from "sap/ui/core/CustomData"
// "JSONModel" required from module "sap/ui/model/json/JSONModel"
// "List" required from module "sap/m/List"
// "StandardListItem" required from module "sap/m/StandardListItem"
function giveAnswer(oEvent) {
  var oItem = oEvent.getSource();      // the StandardListItem
  var sData = oItem.data("theAnswer"); // access the custom data stored under
the key "theAnswer"
  alert("The answer is: " + sData);
}
// create a JSONModel, fill in the data and bind the ListBox to this model
var oModel = new JSONModel(aData);         // aData.questions is an array of
elements like {question:"Some question?",answer:"Some answer!"}
var oList = new List({select:giveAnswer}); // method giveAnswer() retrieves the
custom data from the selected ListItem
oList.setModel(oModel);
// create an item template and bind the question data to the "text" property
var oItemTemplate = new StandardListItem({title: "{question}", press:
giveAnswer, type: "Active"});
// create a CustomData template, set its key to "answer" and bind its value to
the answer data
var oDataTemplate = new CustomData({key:"theAnswer", value: "{answer}"});
// add the CustomData template to the item template
oItemTemplate.addCustomData(oDataTemplate);
// bind the items to the "questions" (which is the name of the data array)
oList.bindAggregation("items", "/questions", oItemTemplate);
```

You can find a productive example in the SAPUI5 test suite by searching for `CustomData` in `sap.ui.core`.

Use in XML Views

In XML views, `CustomData` objects can be written as normal aggregated objects. However, to reduce the amount of code and improve the readability, a shortcut notation has been introduced: You can directly write the data attributes into the control tags. Simply use the following namespace for the respective attributes:

`myNamespace="http://schemas.sap.com/sapui5/extension/sap.ui.core.CustomData/1"`.

The difference between this more formal namespace and the existing MVC namespaces is intentional.

Example

Use without Data Binding

The following example shows how you attach the string "just great" to a button:

```
<mvc:View xmlns:core="sap.ui.core" xmlns:mvc="sap.ui.core.mvc" xmlns="sap.m"
controllerName="my.own.controller"
          xmlns:app="http://schemas.sap.com/sapui5/extension/
sap.ui.core.CustomData/1">
     <Button id="myBtn" text="Click to show stored coordinates data"
app:mySuperExtraData="just great" press="alertCoordinates"></Button>
</mvc:View>
```

The string is returned at runtime by calling `button.data("mySuperExtraData")`.

Example

Use with Data Binding

You can use data binding with the following notation:

```
<mvc:View xmlns:core="sap.ui.core" xmlns:mvc="sap.ui.core.mvc" xmlns="sap.m"
controllerName="my.own.controller"
          xmlns:app="http://schemas.sap.com/sapui5/extension/
sap.ui.core.CustomData/1">
     <Button id="myBtn" text="Click to show stored coordinates data"
app:coords="{data}" press="alertCoordinates"></Button>
</mvc:View>
```

Use in JSON Views

To add custom data to an element in a JSON view, add the following code to the element properties (examples with data binding):

```
customData: {
  Type:"sap.ui.core.CustomData",
    key:"coords",
    value:"{data}" // bind custom data
  }
```

To add multiple data elements, use an array:

```
customData: [{
  Type:"sap.ui.core.CustomData",
```

```
    key:"coords",
    value:"{data}" // bind custom data
  },
  {
  Type:"sap.ui.core.CustomData",
    key:"coords",
    value:"{data}" // bind custom data
  }]
```

In context, this looks as follows:

```
var json =
  {
    Type: "sap.ui.core.mvc.JSONView",
    controllerName:"my.own.controller",
    content: [{
      Type:"sap.m.Panel",
      content:[{
        Type:"sap.m.Button",
        text:"{actionName}",
        press: "doSomething",
        customData: {
          Type:"sap.ui.core.CustomData",
          key:"coords",
          value:"{data}" // bind custom data
        }
      }]
    }]
  };
```

Use in HTML Views

To add custom data objects to a control or an element in HTML views, use a specific HTML attribute with the following syntax: `data-custom-data:my-key="myValue"`. A custom data attribute starts with `data-custom-data:` followed by the name of the key. The dashes convert the respective following character into an upper case character. The value can be either a string or a binding expression:

```
<div data-sap-ui-type="sap.m.Button" data-text="This button is added
dynamically" data-custom-data:my-key="myValue" data-custom-data:my-bound-key="{/
mypath}"></div>
```

Writing Data to the HTML DOM as DATA-* Attribute

SAPUI5 supports writing custom data to the HTML DOM.

These are two use cases, where this feature can be useful:

- To generate markers in the HTML from data binding which then can then be used for data-dependent styling.
- To create stable anchors in the HTML which can be used for automated tests.

A "data-" prefix is added to the key and the result is then written as an attribute into the root HTML element of the control. The `CustomData` value is written as an attribute value.

For this, the key has to be a valid HTML ID and the value has to be a string; otherwise an error is logged.

> **i Note**
>
> HTML attribute names are case-insensitive and browsers may convert the key to lowercase.
>
> Do not write too much data into the DOM.

In JavaScript, you can set the flag as shown in the following code snippet:

```
myButton.data("mydata", "Hello", true); // attach some data to the Button and
mark it as
          "write to HTML"
```

To set the `writeToDom` flag in XML views, the aggregation has to be written in expanded notation:

```
<Button ... >
  <customData>
  <core:CustomData key="mydata" value="Hello" writeToDom="true" />
  </customData>
</Button>
```

This results in the following HTML:

```
<button ...  data-myData="Hello"  ... >
```

This is done similarly in HTML views:

```
<div data-sap-ui-type="sap.m.Button" data-text="This button has custom data
written to the DOM">
   <div data-sap-ui-aggregation="customData">
      <div data-sap-ui-type="sap.ui.core.CustomData" data-key="mydata" data-
value="Hello" data-write-to-dom="true"/>
   </div>
</div>
```

The CSS can now use attribute selectors to check the presence or the value of the custom data attribute:

```
button[data-mydata="Hello"] { border: 3px solid red !important; }
```

Using Predefined CSS Margin Classes

SAPUI5 gives you the option of adding spacing in between controls by adding a margin. A margin clears an area around its respective control, outside of its border.

Unlike paddings, margins are transparent, are not part of the control's clickable area, and they collapse with adjacent margins, meaning that they do not add to each other. For instance, if you have two 32px margins next to each other, the result is that only one 32px margin is displayed, not 64px of space.

All margins predefined in SAPUI5 support right-to-left (RTL) languages: when you add a margin to the left, we make sure that it's displayed on the right if your user has chosen an RTL language such as Hebrew or Arabic. For our CSS classes, we offer four standard sizes, namely tiny (0.5rem or 8px), small (1rem or 16px), medium (2rem or 32px) and large (3rem or 48px).

There are four types of margins available:

- Full margins, which completely surround your control
- Single-sided margins
- Two-sided margins
- Responsive margins, which adapt to the available screen width

Full Margins

If you would like to clear an area **all around your control**, use one of the following margin classes:

- `sapUiTinyMargin`
- `sapUiSmallMargin`
- `sapUiMediumMargin`
- `sapUiLargeMargin`

Single-Sided Margins

For single-sided margins, choose a size (`Tiny`, `Small`, `Medium`, or `Large`, which stands for 8, 16, 32 or 48px respectively) and a direction (`Begin`, `End`, `Top`, or `Bottom`, where `Begin` is left and `End` is right and vice versa in RTL mode). For example, if you need to clear a 32px space to the left of your control (or to the right in RTL mode), you would add the class `sapUiMediumMarginBegin`. You can also add several classes at once, as long as they point to different directions. For example, you would add classes `sapUiLargeMarginEnd` and `sapUiLargeMarginBottom` to clear a 48px space to the bottom and to the right of a control (or to the left in RTL mode).

Here are the classes we provide for single-sided margins:

`sapUiTinyMarginTop`	`sapUiSmallMarginTop`	`sapUiMediumMarginTop`	`sapUiLargeMarginTop`
`sapUiTinyMarginBottom`	`sapUiSmallMarginBottom`	`sapUiMediumMarginBottom`	`sapUiLargeMarginBottom`
`sapUiTinyMarginBegin`	`sapUiSmallMarginBegin`	`sapUiMediumMarginBegin`	`sapUiLargeMarginBegin`
`sapUiTinyMarginEnd`	`sapUiSmallMarginEnd`	`sapUiMediumMarginEnd`	`sapUiLargeMarginEnd`

Two-Sided Margins

If you'd like to clear the space to the left and right or top and bottom of your control, we've provided several two-sided margin classes for you to use. Again, just choose the size and orientation that you need (`BeginEnd`,

TopBottom). For example, if you need to clear a 32px space both to the left and right of a control, you would add the class sapUiMediumMarginBeginEnd. Here are the classes that are available:

sapUiTinyMarginBeginEnd	sapUiSmallMarginBeginEnd	sapUiMediumMarginBeginEnd	sapUiLargeMarginBeginEnd
sapUiTinyMarginTopBottom	sapUiSmallMarginTopBottom	sapUiMediumMarginTopBottom	sapUiLargeMarginTopBottom

We've also provided a set of negative margin classes that add a two-sided (BeginEnd) negative margin of an element. The negative margins are useful for aligning elements with built-in paddings.

sapUiTinyNegativeMarginBeginEnd	sapUiSmallNegativeMarginBeginEnd	sapUiMediumNegativeMarginBeginEnd	sapUiLargeNegativeMarginBeginEnd

Responsive Margins

If your application is supposed to run on smartphone, tablet and desktop, it can be useful to choose your margins depending on the screen width that is available. SAPUI5 now comes with CSS class sapUiResponsiveMargin, which does just that. It works with media queries to determine the available screen width and adapts its margin as follows:

Screen Width	Example
Screen width less than 600px (smartphones): For devices such as these, sapUiResponsiveMargin provides a 16px (1rem) bottom margin to your control. Each of the panels shown in the screenshot is using sapUiResponsiveMargin. As a result, they're all clearing the same 16px area of space below them.	
Screen Width	Example
Between 600px and 1023px (tablets and small desktops): For these, `sapUiResponsiveMargin` provides a 16px (1rem) margin all around your control, as you can see in the screenshot.	Larger than 1023px (large desktops): For these, `sapUiResponsiveMargin` provides 16px (1 rem) top and bottom margin as well as a 32px (2 rem) left and right margin, as shown in the screenshot.	
The following exceptions to these rules exist:

- When your `sapUiResponsiveMargin` control is placed within an `sap.m.SplitApp` master view, it's always provided with a 16px bottom margin and nothing else. Here, the thresholds mentioned previously do not affect your control.
- Within a `SplitApp`'s detail view, there's always a 16px margin all around your `sapUiResponsiveMargin` control, regardless of the available screen width. Usually, the `SplitApp` is responsive as well, though. If it hides its master view because the available screen width isn't sufficient, or if it's running in 'HideMode', your control also ignores the fact that it's placed into a `SplitApp`'s detail view and it becomes responsive again.

Controls with 100% Width

When applying classes with horizontal margins to a control, such as `sapUiSmallMargin` or `sapUiSmallMarginBegin`, for example, make sure that your control doesn't have a 100% width. If your control has a `width` property (which most controls have), set the width value to `auto`, for example:

```
<Panel width="auto" class="sapUiLargeMarginBegin
      sapUiLargeMarginBottom">
```

If your control does **not** have a `width` property but still has a default width of 100%, you can add our CSS class `sapUiForceWidthAuto` to your control, which ensures that the control's default width is overwritten with the value `auto`. An example for such a control is `sap.m.IconTabBar`.

Adding Margin Classes to Your Code

To apply the classes described here in your code, simply add a `class` attribute and the margin class to the respective control tag in your declarative xml views. If you need to add several classes at once (which can be the case if you're using single-sided margins), separate them by a space. Here's a sample snippet containing a panel and an `IconTabBar`:

```
<mvc:View
      height="100%"
      controllerName="sap.m.sample.StandardMarginsEnforceWidthAuto.Page"
      xmlns:mvc="sap.ui.core.mvc"
      xmlns="sap.m">
      .
      .
      .
      <Panel width="auto" class="sapUiLargeMarginBegin sapUiLargeMarginBottom">
          <content>

          </content>
      </Panel>
<IconTabBar
  expanded="{device>/isNoPhone}"
  class="sapUiForceWidthAuto sapUiMediumMarginBeginEnd">
  <items>
        .
        .
        .
  </items>
</IconTabBar>
      .
      .
</mvc:View>
```

If you would like to add margins to javascript code, use the control's `addStyleClass` method. For example: `myPanel.addStyleClass('sapUiLargeMargin')`. Again, if you need to add several classes at once, you can do so by separating them by a space. Make sure that you set the panel's width to `auto` as shown here: `myPanel.setWidth('auto')`.

Removing Margins

If a control comes with a margin that you don't want for some particular reason, you can use one of our convenience classes to remove it. You can either use `sapUiNoMargin` to remove the margins all around your control, or you can choose one or more classes from the following list to remove a margin in one or more particular directions:

- `sapUiNoMarginTop`
- `sapUiNoMarginBottom`

- `sapUiNoMarginBegin`
- `sapUiNoMarginEnd`

Sample

For a detailed example of how our predefined margin classes work, see the Samples.

Using Container Content Padding CSS Classes

For many container controls in SAPUI5, such as a Dialog or a Page, you can define whether the container should have a padding within the content area. A padding clears the area between the container layout and the controls that are displayed in the content area.

You can either choose to have no padding, a small padding, or a responsive padding that is based on the user's screen size.

The following CSS classes for content padding are provided by SAPUI5:

```
sapUiNoContentPadding
sapUiContentPadding
sapUiResponsiveContentPadding
```

The effects of these paddings will be different depending on the container that is being used:

- If the container is defining a padding on its content area by default, then setting `sapUiNoContentPadding` in the application code will remove the padding and thus not display any space between the container layout and the content controls.
- If the container is defining no padding on its content by default, then setting `sapUiContentPadding` will add 1rem (16px) of padding around the content area to layout the content controls.
- Setting `sapUiResponsiveContentPadding` on the container control will add a padding based on the user's screen size. On small screen devices such as smartphones, or when the browser window is resized to a small size, no padding is displayed. On medium screen sizes and applications that are using a `SplitApp`, the control will get 1rem (16px) of padding. Finally, on large screen sizes in full-screen mode, the container control will get 2rem (32px) of padding to the left and right and 1rem (16px) of padding at the top and bottom.

The following list shows examples of controls that support container content padding CSS classes:

```
sap.f.DynamicPage
sap.m.Carousel
sap.m.Dialog
sap.m.IconTabBar
sap.m.List
sap.m.Page
sap.m.Panel
sap.m.Popover
sap.m.ScrollContainer
```

```
sap.m.Table
sap.ui.layout.BlockLayoutCell
sap.ui.layout.DynamicSideContent
sap.ui.layout.HorizontalLayout
sap.ui.layout.VerticalLayout
```

Example

```
<Page class="sapUiResponsiveContentPadding">
```

Example

For a detailed example of how our container padding classes work, see the sample sap.ui.core.ContainerPadding.

Enabling Responsive Paddings

Apply responsive paddings over separate parts of the controls.

> **i** Note
>
> You can enable the responsive paddings only for the SAP Quartz themes.

Usage

Application developers can now apply responsive paddings over separate parts of the controls and align the space distribution properly, according to the width of the control (and not the whole screen). This can be done by using a set of classes, which are available for the different controls.

Applied Paddings

Based on the container's size, one of the following classes is added, and the corresponding padding-left and padding-right are applied:

Container Size (pixels)	Class	Padding-Left and Padding-Right Applied
<= 600	sapUi-Std-PaddingS	1rem
>600	sapUi-Std-PaddingM	2rem

Container Size (pixels)	Class	Padding-Left and Padding-Right Applied
>1024	sapUi-Std-PaddingL	2rem
>1440	sapUi-Std-PaddingXL	3rem

Supported Controls

The following table shows the controls that support responsive paddings. To enable this concept and to add responsive paddings to an element of the controls, add the corresponding classes to the controls, depending on your use case:

Supported Controls	sapUiResponsivePadding--header	sapUiResponsivePadding--subHeader	sapUiResponsivePadding--content	sapUiResponsivePadding--footer	sapUiResponsivePadding--floatingFooter
sap.m.Dialog (sap.m.MessageBox, sap.m.SelectDialog, sap.m.TableSelectDialog)					
sap.m.IconTabBar					
sap.m.ObjectHeader					
sap.m.Page					
sap.m.Popover					
sap.m.TabContainer					
sap.m.Wizard					

> **i Note**
>
> If nessecary, you can further align controls by using the available set of predefined CSS margin classes. For example, you can add negative margins to an element on its left and right sides. For more information, see Using Predefined CSS Margin Classes [page 1046].

Example

```
<Page class="sapUiResponsivePadding--header sapUiResponsivePadding--subHeader
sapUiResponsivePadding--content sapUiResponsivePadding--footer
sapUiResponsivePadding--floatingFooter">
```

For a detailed example, see the Samples for `sap.m.Page`.

How to Enable Responsive Paddings

As a control developer, you can enable application developers to apply responsive paddings, by implementing the `sap.ui.core.util.ResponsivePaddingsEnablement` utility.

Here is an example:

```
ResponsivePaddingsEnablement.call(MyCustomControl.prototype, {
                    header: {suffix: "-myCustomControlHeader"},
                    content: {selector: ".myCustomControlContent"}
                    });
```

As the example demonstrates, there are two ways to select an element:

- Using suffix: This enables you to select an element by its ID.
- Using selector: This covers all possible CSS selections.

To call the utility, when initializing the control, use:

```
MyCustomControl._initResponsivePaddingsEnablement()
```

As a result, application developers will be able to use classes, such as `sapUiResponsivePadding—header` and `sapUiResponsivePadding--content`, to enable the paddings on the respective element.

Field Groups

Group of controls that belong together semantically. This group can be used, for example, for validating the data consistency for the field group.

Field groups are built by means of a common `fieldGroupIds` array for a group that can be set for each control. When the user changes the focus to a control with a different `fieldGroupIds` array, the `validateFieldGroup` event is raised and bubbled in the control hierarchy, that is, the event is propagated to the parent control until it reaches the top most control, or the event is handled and `oEvent.bCancelBubble` is set to `true`. The application developer can now validate the fields within the group. The `validateFieldGroup` event is also raised if the user presses Enter in a field without any modifier keys.

Example: Validation of Credit Card Information

Depending on the credit card vendor, different validation rules can be implemented for a field group, for example:

- Vendor 1: First digit must be a 3 and second digit must be a 4 or 7, the valid length is 15 digits
- Vendor 2: First digit must be a 5 and second digit must be in the range from 1 to 5 inclusive, the valid length is 16 digits

Plenty of other validation rules for vendors exist. In addition to this, the expiry date must not be in the past and, in case of Vendor 1, is only allowed to be 4 years in the future.

Defining a Field Group ID

`fieldGroupIds` is a property of all `sap.ui.core.Control` instances and can be set there as an array of strings. The developer has to make sure that the ID is unique. Field group IDs can be added as a comma-separated string as it is usually done in an xml view declaration.

```
var myInput1 = new sap.m.Input({fieldGroupIds:["MyGroup","MyGroup2"]}),
myInput2 = new sap.m.Input({fieldGroupIds:["MyGroup","MyGroup2"]});
```

```
//XMLView declaration of multiple groups
<input fieldGroupIds="MyGroup,MyGroup2" />
```

Validating Field Groups

The `validateFieldGroup` event is raised on the control that lost the focus and at least one field group was left. The event bubbles up the control hierarchy. In the example below, the surrounding `VerticalLayout` is handling the event for its fields.

```
var myVerticalLayout = new sap.ui.layout.VerticalLayout({content:[myInput1,
myInput2], validateFieldGroup: function(oEvent) {
    var aFieldGroup = oEvent.getParameters().fieldGroupIds;
    if (aFieldGroup.indexOf("MyGroup") > -1) {
        //do validation
        oEvent.bCancelBubble = true; //stop bubbling to the parent control
    }
}});
```

Accessing Controls in a Field Group

In some scenarios, it is required to find all controls that belong to a specific field group, or to all controls with a `fieldGroupId`. For this, the control implements the public `getControlsByFieldGroupId` method that gets a list of child controls in the application code.

```
var aAllControlsWithFieldGroupId =
myVerticalLayout.getControlsByFieldGroupId();              //all where
fieldGroupId is not empty
var aMyGroupControls             =
myVerticalLayout.getControlsByFieldGroupId("myGroup");     //exact matches to
myGroup
```

Similar to the above you can use the `byFieldGroupId` method of `sap.ui.Core` to all controls with certain field group IDs.

```
var aAllControlsWithFieldGroupId =
sap.ui.getCore().byFieldGroupId();              //all where fieldGroupId is not
empty
var aMyGroupControls             =
sap.ui.getCore().byFieldGroupId("MyGroup");     //exact matches to myGroup
var aNotGrouped                  =
sap.ui.getCore().byFieldGroupId([]);            //exact empty array (default
value of fieldGroupIds)
```

Using the `fieldGroupId` With Composite Controls

Composite controls that derive from control base class automatically support setting a `FieldGroupId`. Nevertheless, the `FieldGroupId` is not propagated to inner controls of the composite control as they are unknown to the SAPUI5 framework. Therefore, a composite control needs to propagate the `FieldGroupId` on its own. For all internally aggregated controls, the `FieldGroupId` should be propagated as follows:

```
MyCompositeControl.prototype.setFieldGroupIds = function(vValue,
bSuppressInvalidate) {
    this._myAggregatedInnerControl.setFieldGroupIds(vValue, bSuppressInvalidate);
    this.setProperty("fieldGroupIds",vValue, bSuppressInvalidate);
}
```

Note

For a control with a `fieldGroupId` that currently has the focus, the following applies:

- If the control is destroyed before the focus is moved to another control, the `validateFieldGroup` event is not fired.
- If the control changes its `fieldGroupIds`, the `validateFieldGroup` event is fired for the new `fieldGroupIds` and **not** for the old.

Sample: `Field Groups`

Declarative Support

Declarative programming allows you to define the UI within the HTML document as elements.

For this, SAPUI5 provides the `sap.ui.core.plugin.DeclarativeSupport` plugin that can be included either as required or marked as a module in the initial bootstrap script tag. The plugin parses the document and converts its tags with special attributes into SAPUI5 controls.

Declarative support is aware of properties, associations, events, and aggregations in a SAPUI5 control manner. This means that you can specify them within the markup of the HTML document either as data attributes or as child elements.

The following sections provide an overview of the declarative support and introduce the use of declarative support in SAPUI5.

Example

The following example shows the concept by combining a `sap.m.input` with a `sap.m.Button` control. When you click the button, the value of the text field is displayed in an alert box:

```
<!Doctype HTML>
<html>
<head>
    <title>Declarative Programming for SAPUI5 - sample01</title>
    <script id="sap-ui-bootstrap"
         type="text/javascript"
         src="resources/sap-ui-core.js"
         data-sap-ui-theme="sap_belize"
         data-sap-ui-libs="sap.m"
         data-sap-ui-modules="sap.ui.core.plugin.DeclarativeSupport"
         >
    </script>
</head>
<body class="sapUiBody">
  <div data-sap-ui-type="sap.m.Input" id="message" class="my-button" data-
value="Hello World"></div>
  <div data-sap-ui-type="sap.m.Button" data-text="Click me!" data-
press="handlePress"></div>
</body>
</html>
```

Summary: Attributes Used by Declarative Support

The table summarizes the attributes used by declarative support and gives examples.

Attribute	Description	Example
`data-sap-ui-type`	Type of control	`<div data-sap-ui-type="sap.m.Button"></div>`
`data-sap-ui-aggregation`	Defines the aggregation that shall be used for the element or child element	`<div data-sap-ui-type="sap.m.Panel"><div data-sap-ui-aggregation="content" data-sap-ui-type="sap.m.Button" data-text="My Button"></div></div>`
`data-sap-ui.default-aggregation`	Sets or overrides the default aggregation of a control	`<div data-sap-ui-type="sap.m.Panel" data-sap-ui-default-aggregation="headerToolbar"><div data-sap-ui-type="sap.m.Toolbar"></div></div>`
`id`	Defines the ID property of a control	`<div data-sap-ui-type="sap.m.Button" id="myButton"></div>`
`class`	Adds a style class to the control	`<div data-sap-ui-type="sap.m.Button" class="myButton"></div>`

Enabling Declarative Support

Declarative support needs to be enabled in the HTML document by adding an attribute to the SAPUI5 bootstrap script tag.

This is done as follows:

```
data-sap-ui-modules="sap.ui.core.plugin.DeclarativeSupport"
```

SAPUI5 then requires (loads) the plugin `sap.ui.core.plugin.DeclarativeSupport`. When started, the plugin parses and enhances special HTML tags in the HTML document. The complete bootstrap script tag for SAPUI5 (based on a CDN version) looks as follows:

```
<script id="sap-ui-bootstrap"
  type="text/javascript"
  src="resources/sap-ui-core.js"
  data-sap-ui-theme="sap_belize"
  data-sap-ui-libs="sap.m"
  data-sap-ui-modules="sap.ui.core.plugin.DeclarativeSupport"
  >
</script>
```

Defining Controls

For declarative support, define the controls in your HTML document as HTML tags.

For this, use the following data attribute that defines the SAPUI5 control that should be rendered in the HTML tag by using the HTML tag as its UI area:

```
data-sap-ui-type="sap.m.Button"
```

Rendering a button in the body of an HTML document without setting any property, association, event, or aggregation looks as follows:

```
<body>
  <div data-sap-ui-type="sap.m.Button"></div>
</body>
```

> **i** Note
>
> Make sure that you close the tags properly. HTML5 does not support self-closing tags.

> **i** Note
>
> All attributes used to define properties, associations, events, or aggregations are data attributes except for attributes that exist in HTML, for example `id` or `class`. Data attributes are prefixed with `data-*`, for example `data-text`.

Declarative Support: Properties

For setting a property, define the property as a data attribute of the corresponding HTML tag.

To add text to the button, add the attribute `data-text` to its HTML tag:

```
<div data-sap-ui-type="sap.m.Button" data-text="HelloWorld"></div>
```

> **i** Note
>
> To define a property with upper case characters, you have to "escape" them with a dash character, similar to CSS attributes. The following code gives an example:
>
> ```
> <div data-sap-ui-type="sap.ui.commons.ApplicationHeader" data-display-
> logoff="false" data-display-welcome="false">
> ```
>
> As the name of the attributes of HTML tags are case-insensitive, the properties `displayLogoff` and `displayWelcome` of the `ApplicationHeader` control have to be "escaped" as `data-display-logoff` and `data-display-welcome` for the name of the attributes of the HTML tag. Keep this in mind when matching properties, associations, or events as an attribute of the HTML tag.
>
> The `id` attribute defines the ID of a control:
>
> ```
> 
> ```

To add a CSS class to the control, use the class attribute:

```
<div data-sap-ui-type="sap.m.Button" class="my-button"></div>
```

Declarative Support: Associations

An association is defined as a data attribute of the HTML tag. Instead of passing the reference to another control you define the ID of another control.

The following code gives an example:

```
<div data-sap-ui-type="sap.m.Label" data-text="Message:" data-label-
for="message"></div>
<div data-sap-ui-type="sap.m.Input" id="message"></div>
```

The code snippet defines the link between `Label` and `Input` by using the ID of `Input` as a value for the `data-label-for` attribute of the `Label`.

Declarative Support: Events

The value of the event data attribute contains the name of a JavaScript function which will be used as callback once the event has been triggered.

The following code snippet gives an example how a change of `Input` results in an alert with its new value when the focus is lost:

```
<script>
  function handleChange (oEvent) {
    alert (oEvent.getSource().getValue());
  }
</script>
<div data-sap-ui-type="sap.m.Input" data-value="Change me!" data-
change="handleChange"></div>
```

Currently, SAPUI5 only supports to specify the name of a callback function. You can define callback functions within any class, see the following code example:

```
<div data-sap-ui-type="sap.m.Input" data-value="Change me!" data-change=
"my.company.MyClass.handleChange"></div>
```

Declarative Support: Aggregations

Aggregation support is required to allow nested controls for layout containers and/or add elements to a control, for example, for `ComboBox`.

SAPUI5 uses the control's default aggregation as default. If, for example, the panel control has the default aggregation content, all child elements of the `data-sap-ui-type="sap.ui.commons.Panel"` element are added to this aggregation:

```
<div data-sap-ui-type="sap.ui.commons.Panel">
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 1"></div>
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 2"></div>
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 3"></div>
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 4"></div>
</div>
```

The markup in the example above generates an instance of the `sap.ui.commons.Panel` control and adds implicit four buttons to the default aggregation content of the control.

You can also explicitly declare an aggregation. In general, an explicit aggregation is expressed with a meta HTML tag between the parent controls HTML tag and the HTML tags of the children. The following code adds four buttons explicitly to the "content" aggregation of the declared panel:

```
<div data-sap-ui-type="sap.ui.commons.Panel">
  <div data-sap-ui-aggregation="content">
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 1"></div>
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 2"></div>
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 3"></div>
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 4"></div>
  </div>
</div>
```

For aggregations with the cardinality "0..1" the `"data-sap-ui-aggregation"` attribute can be written directly to the control tag:

```
<div data-sap-ui-type="sap.ui.commons.Panel">
  <div data-sap-ui-aggregation="title" div data-sap-ui-
type="sap.ui.commons.Title" data-text="My Panel"></div>
</div>
```

The default aggregation of the declarative support is usually also the default aggregation of the control as defined in the control's meta information. However, when no default aggregation is set or another aggregation should be used as a default, for example to avoid unnecessary meta tags, it can be useful to define a so-called default aggregration attribute on the parent controls HTML tag. This is done as follows:

```
data-sap-ui-default-aggregation="title"
```

With this, all children which are not included in the `data-sap-ui-aggregation` meta tag are added to the default aggregation. This is shown in the following example:

```
<div data-sap-ui-type="sap.ui.commons.Panel" data-sap-ui-default-
aggregation="title">
  <div data-sap-ui-type="sap.ui.commons.Title" text="My Panel"></div>
  <div data-sap-ui-default-aggregation="content">
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 1"></div>
    <div data-sap-ui-type="sap.ui.commons.Button" data-text="My Button 2"></div>
  </div>
/div>
```

You can now apply this to the `MatrixLayout` as follows:

```
<div data-sap-ui-type="sap.ui.commons.layout.MatrixLayout" data-layout-
fixed="false">
  <div data-sap-ui-type="sap.ui.commons.layout.MatrixLayoutRow">
    <div data-sap-ui-type="sap.ui.commons.layout.MatrixLayoutCell">
      <div data-sap-ui-type="sap.ui.commons.TextField" data-value="Hello
World"></div>
    </div>
    <div data-sap-ui-type="sap.ui.commons.layout.MatrixLayoutCell">
      <div data-sap-ui-type="sap.ui.commons.Button" data-text="Hello World"></
div>
    </div>
  </div>
</div>
```

Or you can add `ListItems` to a `ComboBox`:

```
<div data-sap-ui-type="sap.ui.commons.ComboBox" data-value="Item 1">
  <div data-sap-ui-type="sap.ui.core.ListItem" data-text="Item 1"></div>
  <div data-sap-ui-type="sap.ui.core.ListItem" data-text="Item 2"></div>
  <div data-sap-ui-type="sap.ui.core.ListItem" data-text="Item 3"></div>
  <div data-sap-ui-type="sap.ui.core.ListItem" data-text="Item 4"></div>
  <div data-sap-ui-type="sap.ui.core.ListItem" data-text="Item 5"></div>
</div>
```

Declarative Support: Data Binding

Declarative support in SAPUI5 also enables data binding.

Just add the model path in curly brackets and bind the model to the control (or parent control):

```
<div data-sap-ui-type="sap.m.Button" data-text="{/stringValue}" data-
enabled="{model2>/booleanValue}"></div>
```

0..n aggregations can define templates to use for the list binding:

```
<div data-sap-ui-type="sap.m.Carousel" data-content="{/buttons}">
    <div data-sap-ui-type="sap.m.Button" data-text="{title}"></div>
</div>
```

In the example above, the button template is used for the carousel content data binding.

Data Binding [page 815]

Compiling Declarative HTML

SAPUI5 provides a plugin for controls that are defined as declarative markup on startup time.

To compile the declarative UI markup deferred, for example, when the markup is dynamically loaded and added to the DOM you can call the `sap.ui.core.plugin.DeclarativeSupport`.compile method, see the following code snippet:

```
<div id="button">
  <div data-sap-ui-type="sap.m.Button" data-text="This button is added
dynamically"></div>
</div>
<script>

sap.ui.core.plugin.DeclarativeSupport.compile(document.getElementById("button"));
</script>
```

Error, Warning, and Info Messages

SAPUI5 provides a central place for storing and managing info, warning, and error messages.

Messages can be used to notify the user about specific states of the application and can help the user to correct their incorrect inputs. The central `MessageManager` for storing messages is available globally by calling `sap.ui.getCore().getMessageManager()` and the central `MessageModel` for managing messages is available by calling `sap.ui.getCore().getMessageManager().getMessageModel()`.

Message Object Properties

The following properties of `sap.ui.core.message.Message` instances are important:

- Target: Describes the part of the application to which the message applies. If the target is empty, the message applies to the entire application. The target format depends on the used message processor. Currently,SAPUI5 supports two types of targets:
  - Control IDs with control properties: The `sap.ui.core.message.ControlMessageProcessor` propagates these messages to the affected control.
  - Binding path: The `sap.ui.model.Model` propagates these messages to affected bindings.
- Message processor: The object that handles the message in the application and propagates the message to correct controls, bindings, or other objects, see `sap.ui.core.message.ControlMessageProcessor` in the API reference.
- Type: Defines the severity of the message; possible types are: error, warning, info, and success, see `sap.ui.core.MessageType` in the API reference.
- Message text: The actual message text describing the issue. This text is shown to the user.
- Persistent: This property influences the lifecycle of the message. Non-persistent messages are cleaned up by the framework messaging lifecycle, persistent messages have to be removed manually by the application.

Message Creation

There are several ways to create messages automatically and push them into the central message model:

- Validation messages refer to a control. They are created by the SAPUI5 framework when data is parsed, formatted, and validated according to defined data types, see Formatting, Parsing, and Validating Data [page 854]. Such messages are propagated to one specific control. For more information, see Validation Messages [page 1065].
- OData V2 messages refer to a binding path. They are typically managed by the server and are changed every time the back end responds to a request. Such messages are propagated to all bindings with the specific binding path. For more information, see OData V2 Messages [page 1067].

You can also create messages manually or extend the messaging features provided by the framework:

- You can create custom messages manually via the central `sap.ui.core.message.MessageManager` APIs. For these manually created messages, the application has to ensure a proper message lifecycle.
- For custom target formats, you can use the custom message processor. The own message processor has to inherit from the class `sap.ui.core.message.MessageProcessor`.
- If the used back end serves messages in a special way, you can use your own implementation of `sap.ui.core.message.MessageParser`. For more information, see Implementing Your Own OData V2 Message Parser [page 1071].

Validation Messages

Validation messages are either created by the framework and processed by the `sap.ui.core.message.ControlMessageProcessor` or manually by the application.

Target

The target of a validation message can be empty. In this case, the message has no specific target and is relevant for the whole application. If a target is set, the target is a string consisting of a control ID, a slash ("/"), and the name of the property to which the message applies.

Example: `label0/text`

Lifecycle

Validation messages are added with a target referencing a control and its specific property. The messages are kept until a validation message for the property is created and assigned. If new data for the same property is received from the server, the valdation messages are erased unless their `persistent` property is set to `true`.

Automatically Created Messages

Validation messages are generated by the framework type validation when data changes. If a bound property has an assigned type, the validation can trigger the message creation. To activate the automatic message creation, the following options exist:

- Component:
  You can activate the automatic message generation in the component metadata or as a parameter when instantiating the component as follows:

```
// "UIComponent" required from "sap/ui/core/UIComponent"
// "ComponentContainer" required from "sap/ui/core/ComponentContainer"
UIComponent.extend("MyComponent", {
    metadata  : {
        version  : "1.0" ,
        handleValidation  : true
    }
});
```

```
var oComponentContainer = new ComponentContainer("MyComponentContainer", {
    name: "MyComponent",
    id: "myComponentId",
    handleValidation: true
});
```

- Descriptor for Applications

You can activate the automatic message generation in the `"sap.ui5"` section of the `manifest.json` file as follows:

```
"sap.ui5": {
       "handleValidation": true
}
```

- Control
  You can activate automatic message generation for controls by registering the control in the message manager as follows:

```
// "Input" required from "sap/m/Input"
// "TypeFloat" required from "sap/ui/model/type/Float"
var oInput = new Input({
    value: { path: "/Products(1)/Price", type: new TypeFloat() }
    value: { path: "/Products(1)/Price", type: new sap.ui.model.type.Float() }
});
sap.ui.getCore().getMessageManager().registerObject(oInput, true);
```

> **i Note**
>
> If you don't set the second attribute of `sap.ui.core.message.MessageManager.registerObject` to `true`, the event is canceled without any message, see `sap.ui.core.message.MessageManager.registerObject` in the API reference.

Manually Created Messages

You can also create validation messages manually and add them to the message manager. If you add the message to a control property that is bound and validated by a data binding type, your message gets deleted when new validation results from the type comes in. You can override this behavior by setting the `persistent` property of the message to `true`.

```
var oMessageProcessor = new sap.ui.core.message.ControlMessageProcessor();
var oMessageManager  = sap.ui.getCore().getMessageManager();
oMessageManager.registerMessageProcessor(oMessageProcessor);
var oInput = new sap.m.Input({
    id: "myInputId",
    value: { path: "/Products(1)/Price" , type: new sap.ui.model.type.Float() }
});
oMessageManager.addMessages(
    new sap.ui.core.message.Message({
        message: "ZIP codes must have at least 23 digits",
        type: sap.ui.core.MessageType.Error,
        target: "/myInputId/value",
        processor: oMessageProcessor
     })
);
```

OData V2 Messages

OData V2 messages are either created automatically by `sap.ui.model.odata.ODataMessageParser` and processed by the `sap.ui.model.odata.v2.ODataModel` or can be created manually by the application.

Target

The target of these messages can be empty. In this case, the message has no specific target and is relevant for the whole application. If a target is set, it must correspond to a binding path which is then used to propagate the message to the corresponding bindings. If these bindings belong to a control that implements the `refreshDataState` function, the control is able to react to data state changes.

Lifecycle

OData V2 messages are kept until a message from the server for the same path arrives. The server always sends all messages for a specific target which means that all current messages are replaced with the ones sent by the server, except for `persistent` UI messages. Back-end messages with property `transition` set to `true` are parsed to `persistent` UI messages.

Manually Created Messages

To create messages manually that are handled like OData messages, use `model` as message processor as follows:

```
// oMyModel is defined elsewhere...
// "Input" required from module "sap/m/Input"
// "TypeFloat" required from module "sap/ui/model/type/Float"
// "Message" required from module "sap/ui/core/message/Message"
// "coreLibrary" required from module "sap/ui/core/library"
var oMessageManager = sap.ui.getCore().getMessageManager();
oMessageManager.registerMessageProcessor(oMyModel);
var oInput = new Input({
    id: "myInputId",
    value: { path: "/Products(1)/Price", type: new TypeFloat() }
});
oMessageManager.addMessages(
    new Message({
        message: "Price must contain only numbers",
        type: coreLibrary.MessageType.Error,
        target: "/Products(1)/Price",
        processor: oMyModel
    })
);
```

Automatically Created Messages

The `sap.ui.model.odata.v2.ODataModel` supports automatic parsing of OData V2 messages by means of `sap.ui.model.odata.ODataMessageParser`.

For other back-end service types, an application can implement its own parser, see Implementing Your Own OData V2 Message Parser [page 1071].

OData V2 Message Parser

The `ODataMessageParser` is created automatically for all `v2.ODataModel` instances and parses all responses from the server. The `ODataModel` implements the message processor interface and is used to propagate the messages to the message manager. In case of an error response, the response body is parsed for error messages. In case of a successful response, the "sap-message" header is parsed as a JSON-formatted error object. The name of the header field can be changed by calling the `setHeaderField()` method on the `ODataMessageParser`.

Troubleshooting for the OData V2 Message Parser

In this section you find known limitations of the `ODataMessageParser` and how you can resolve issues with unexpected numbers of UI messages.

Duplicate messages with different targets

Mulitple OData changes that are part of the same change set are send as batch request to the back end, for example:

- Change operation (POST Product('id=123'))
- Change operation (POST Product('id=456'))

If one change operation fails, the back end rolls back all operations of the change set, but returns only a single message, for example:

```
{
  "code": "MYCODE/111",
  "message": "Invalid input!",
  "severity": "error",
  "target": ""
}
```

This leads to two UI message objects with the following message targets:

- "/Product('id=123')"
- "/Product('id=456')"

Solution: The message target has to be defined in the back-end error message. By this, only one UI message which represents the failed change is created and pushed into the central message model. Otherwise, the `ODataMessageParser` creates a separate error message for every change included in the change set.

Duplicate messages with the same target

The OData service error response can also contain multiple inner-errors to deliever more than one error message to the front end. The inner-error messages should generally be used to describe the problem in more detail, for example

```
{
  "code": "MYCODE/111",
  "message": "Failed operations!",
  "severity": "error",
    "details": [
    {
      "code": "MYCODE/222",
      "message": "Object 1 already exists!"
      "severity": "error"
    },
    {
      "code": "MYCODE/222",
      "message": "Object 2 already exists!"
      "severity": "error"
    },
    ...
  ]
}
```

Solution: The outer-error will also be parsed into a separate UI error message. These general error messages, such as *Failed operations*, can be confusing for end users. To prevent these general UI messages, the outer-error message has to have the same error code and error message text ("message" property) as an inner-error. This way, the outer message information is ignored, that is, not parsed into a UI message, since there already is an inner-error message with more details that represents the same issue.

Hint: The duplicate detection only works for request body error messages. For request header error messages, the unwanted outer-error must be filtered out in the front end. As an alternative, the outer-error could already represent the first detailed error, see the example error with message *Object 1 already exists*.

Scenario 3: Missing UI messages

This can happen when an OData entity is changed and the same entity is requested again shortly afterwards. The change and the read operation could also be part of the same batch request, for example:

- Change operation ('POST' request with target "Product('id=123')")
- Read operation ('GET' request with target "Products")

If the change operation fails, a UI message is created. But this UI message is deleted directly afterwards via the messaging lifecycle since the read operation of the same entity does not return any message. There are two options to get the expected behavior in this scenario:

Solution 1: Mark the UI message as persistent. By this, the message lifecycle will not delete the UI message, but the application has to take care of cleaning up such messages by using the `sap.ui.core.message.MessageManager` APIs.

Solution 2: Defer the read operation. By this, the UI message is also not deleted, but the application has to make sure the read operation is triggered at an appropriate point in time.
